In all these examples, as well as in the data from which the preceding tables were computed, Troughton's micrometer was used as a celestial eye-piece, where the object was consequently inverted, which is the manner in which this micrometer was intended to be used; but according to the construction of the modern terrestrial eye-tube, this micrometer may be substituted, by help of an adapter, for the two glasses at the eye-end of this tube, in which situation the magnifying power is very considerably increased, and consequently the scale rendered capable of measuring smaller portions of a second, than in the usual way, particularly when there is light enough in the field of view, *i. e.* when the object-glass has a large diameter. When the micrometer in question is applied to the eye-end of the terrestrial tube of the telescope of 45.75 inches, one turn is equal to only 16".03, which shews the power to be somewhat greater than when the 118.8 inches telescope was used as a celestial telescope with the same micrometer; and with the telescope of 63.5 inches, which has three pair of separate field-glasses, the terrestrial powers with the said micrometer gives the respective values of one turn of the screw 9".97, 7".98, and 5".15; so that this telescope has four various values of the micrometrical scale, which may be used in succession for measuring the same angle, according to circumstances, and each variety may have a separate table computed for its particular use. This application of Troughton's micrometer to the terrestrial tube, and the additional pairs of field-glasses, were contrived by the author of this article, and led to another addition, which in itself admits of still greater varieties. On observing that the modern terrestrial eye-tube is in fact a *compound microscope*, it occurred to him, that there are three modes of increasing the power of this instrument; first, by shortening the compound focus of the eye-glasses; secondly, by shortening the compound focus of the pair of field-glasses; and thirdly, by lengthening the distance between the compound eye-glass and compound field-glass (or object-glass of the microscope). The two former modes had now been tried, and afforded the varieties in the measures which we have specified: the last one was therefore resorted to thus; a tube was made to slide within the terrestrial tube, after its own eye-piece was withdrawn, and the micrometer was made to screw into this moveable tube, so as to vary the distance of the micrometer glasses from the field-glasses of the telescope at pleasure. The result proved as was expected; every new position for distance gave a new value to the scale of the micrometer, and the two extremes of these values, with the 63.5 inch telescope, were 10" and 5" respectively *per* revolution of the screw; at least the points were found by experiment on the sliding tube, where these values, and also the intermediate ones 9", 8", 7", and 6" *per* revolution, were marked with a graver. The distances of these points depended on the field-glasses used with the sliding tube; and three sets of points were inserted, to correspond to the three pairs of field-glasses, any one of which admitted the scale to be subdivided into tenths of a

second. This mode of applying a sliding micrometer in the terrestrial tube is as useful as novel; for when the position is made for an exact number of seconds *per* turn of the screw, the tables are dispensed with; the only operation being to multiply the number of turns by the number of seconds belonging to the position of the sliding tube, and then to reduce them to minutes by 60 as a divisor. A few examples will render these new methods of using the micrometer perfectly intelligible, and will at the same time shew that they contribute greatly to accuracy, by a species of repetition of the measure, of which they are capable. We will first exemplify the method without the sliding tube.

1. The measures of Jupiter's diameter, taken by the 63.5 inch telescope on the 19th of April 1816, were as follow:

By Troughton's micrometer used	}	
as a celestial eye-piece	-	$1.43 \times 31.3 = 44.8$
By N ^o 1. of the field-glasses with	-	$4.23 \times 9.97 = 42.2$
the terrestrial tube	-	
By N ^o 2. of ditto	-	$5.53 \times 7.98 = 44.13$
By N ^o 3. of ditto	-	$8.32 \times 5.15 = 42.85$
		$4)173.98$
Average of the four measures	-	$= 43.495$

The values of the three field-glasses had been taken by terrestrial measurement at 700 feet, on the 31st of March 1816, and may require farther correction.

2. On the 30th of April 1816, Jupiter being very nearly in opposition, his diameter was measured with the 45.75 inch telescope, which has only two varieties, a celestial and a terrestrial application of the micrometer, and the result was thus: *viz.*

By the celestial measure, taken to the	}	
right of zero	-	1.04 turns.
By the same, taken to the left of zero	-	1.05 ditto.
		$2)2.09$
		$1.045 = 43.52$
By the terrestrial measure $2.72 \times 16''.03$	$= 43.50$	
		$2)87.02$

The average of the celestial and terrestrial measures = 43.51

3. On the 25th of October 1815, the following measures were taken of the diameter of Mars with Troughton's micrometer attached to the sliding tube of the telescope 63.5 inches; *viz.*

	Turns.	"	"	
First position at the dot of 7"	}			
with third field-glass	-	3.43×7	$= 24.01$	
Second position with ditto	-	2.96×8	$= 23.68$	
Third position with ditto	-	2.68×9	$= 24.12$	
Fourth position with ditto	-	2.40×10	$= 24.00$	
With N ^o 1. field-glass and its	}			
dot 4"	-	6.0×4	$= 24.00$	
With N ^o 2. field-glass and its	}			
dot 8"	-	3.0×8	$= 24.00$	
With the micrometer used as a	}			
celestial eye-piece	-	0.77×31.3	$= 24.10$	
				$7)167.91$
				23.987

These

TELESCOPE.

These observations of Mars were made near the meridian, when he was a little past opposition, and consequently when his diameter was near a maximum, which circumstance we mention, because astronomers have given very discordant accounts of the apparent diameter of this planet; and perhaps no determination has been more accurate than we have here given.

4. The sun's diameter was measured at noon on the 24th of September 1816, by Troughton's micrometer adapted to the 30.15 inch telescope, in the following manner; viz.

By the celestial power	-		29.21	×	65 ^{''} .7	=	31 ['] 59 ^{''} .1	
By the terrestrial, with the eye-tube slid to dot 30 ^{''}	}		63.92	×	30	=	31 57.6	
			68.50	×	28	=	31 58.0	
By the terrestrial, at dot 28 ^{''}			76.74	×	25	=	31 58.5	
							4)	127 53.2

Average measure	-		=	31 58.3
By the Nautical Almanac	15' 59 ^{''} .1	×	2	= 31 58.2

On the sliding tube of this telescope, the dots on the scale run from 31^{''} to 19^{''}, at which dots the powers are to each other inversely as these numbers; but the whole diameter of the sun cannot be taken on the scale of the micrometer when a greater power is used, than when the position is at dot 25^{''}, or middle dot of the sliding tube, where the power is about 82.

In these four examples, the diameters measured were the vertical diameters, for taking which Troughton's micrometer is peculiarly adapted; but the horizontal diameter of a body in motion cannot be taken with the same accuracy with this instrument, on account of the difficulty of keeping the extreme edges of the object in contact with the spider's lines, while the final adjustment of the measure is making. For this purpose, Dollond's divided object-glass micrometer is more convenient, and may have its scale appreciated, and the values thereof tabulated in the way we have already explained. For instance, we obtained a divided object-glass, with the requisite adjustments both for circular motion and for the separation of the centre of the semi-lenses, of three inches and a half diameter, and fitted it over the object-end of the 45.75 inch achromatic of Tulley, while the original object-glass, of the same dimensions, remained in its place. The focus of this divided object-glass was so long, that it shortened the original focus only to 40.3 inches. The scale of the object-glass is divided into inches and twentieth parts of an inch, one of which parts or subdivisions is again reduced by a vernier into twenty-five subordinate parts, so that $\frac{1}{25}$ of $\frac{1}{20}$, or $\frac{1}{500}$ th of an inch, is the smallest quantity appreciable by the vernier. On the 9th of August 1816, when the sun's diameter was 31' 37^{''}, or 1897^{''}, the opposite limbs of the two apparent images of the sun coincided when the scale indicated three inches, one-twentieth part, and eleven towards 25 on the vernier, after an allowance was made for the index error by a crossed observation of a very small angle. Now these numbers reduced into the lowest denomination, give 1536 parts of the vernier, and

$$\frac{1897''}{1536} = 1''.235 \text{ is the value of one of those parts; but by}$$

a terrestrial measurement, to be explained hereafter, the value taken at 700 feet distance, with a correction for want of parallelism of the rays at this distance, the value came

$$\text{out } \frac{888''}{713} = 1''.245; \text{ the average of which two determina-}$$

tions, unconnected with each other, is 1^{''}.24 for each unit read on the vernier, and this determination was afterwards confirmed by an observation of the sun taken on the 25th

September 1816, viz. $\frac{1919''}{1549} = 1''.24$ very nearly. After

having given a value to Dollond's micrometer thus fitted up, on the 21st of August 1816, the diameter of Saturn's ring was measured when its longer diameter was very nearly horizontal, both to the right and left of zero, and was found equal to one subdivision and 7.7 on the vernier, or 25 + 7.7 = 32.7 parts of the vernier; then 32.7 × 1^{''}.24 = 40^{''}.548 is the measure of the greatest length of Saturn's ring taken near the meridian, when the passage was at nearly 28 minutes past eleven P.M.; and, consequently, when the planet was at no greater distance than eight days from opposition. On the 4th of August 1815, the greatest diameter of Saturn's ring however, measured with Troughton's micrometer attached to the 63.5 inch telescope, had been found by careful measurement = 1.50 × 31^{''}.3 = 46^{''}.95, the planet being then only three days from opposition. By the same apparatus the ring had been made 48^{''}.2 on the 10th of September 1815, and on the 25th of the same month only 43^{''}. These discrepancies shew that no dependence can be placed in horizontal measures made with Troughton's micrometer when the object is in *apparent motion*, but for all other measures of small angles, it is no doubt the best that has been yet invented.

Dr. Brewster's micrometer has the same advantage as Dollond's, when the divided lens is used as the sliding lens within the tube; but the power of the patent telescopes hitherto constructed is so small, that an angle can seldom be measured with it nearer than to 10^{''}, and frequently not so near. The principle, however, is applicable to telescopes of larger dimensions.

When Dollond's and Troughton's micrometers are both applied to the telescope of 45.75 inches, the value of the scale of Troughton's becomes altered from 43^{''}.5 to 49^{''}.4, namely, in the inverse ratio of the diminished focus; and they may both be used with great convenience at the same time, in which case, one may measure the angular length and the other the angular breadth of the same body; or, if the body be celestial, one may give the horizontal and the other the vertical dimensions at the same instant. This mode of applying two micrometers, one optical and the other mechanical, at the same time, affords a mutual check on the measures of each, when the body is round, like one of the heavenly bodies, and gives a very satisfactory result, when it can be adopted. When Troughton's micrometer is used as a celestial eye-piece, along with Dollond's micrometer attached to the telescope 45.75, shortened to 40.3, the double images are formed beyond both eye-glasses, reckoning from the eye, and gives there 1^{''}.24 as the value of one stroke on the vernier; whereas when a common celestial eye-piece is used with Dollond's, the second glass of the compound piece shortens the focus of the object-glass a little, and the images are seen between the two glasses of the eye-piece; consequently the value of Dollond's micrometer varies a trifle with every different eye-piece, which is not the case with Troughton's, where the image is always in the unaltered focus of the object-glass. On the 26th of September 1816, a careful series of observations was made of the sun's diameter with both Troughton's and Dollond's micrometers used at the same time, when the former gave 38.85 × 49^{''}.4 = 31' 59^{''}.2, and the other 15.47 (3 in. 1 div. 22 on vern.) × 1^{''}.21 = 31' 58^{''}.28, the diameter of the sun by the Nautical Almanac being

TELESCOPE.

being $31' 59''.2$ horizontally, and $31' 57''.9$ vertically, at the altitude of 38° .

Terrestrial Measures.—In the examples which we have given of celestial angular measures taken, by a micrometrical telescope, no correction of the measured angle was necessary; because the rays of light coming from these objects may be considered as parallel on entering the object-glass, and as always converging to the same focal point, where the image is formed; hence the magnifying power of the celestial telescope does not vary. But when terrestrial objects are viewed at different distances, there is a deviation from parallelism in the course of the rays, which increases in the inverse ratio of the distance, and which lengthens the focus of the object-glass, and consequently increases the power of the instrument, even with the same glasses. This alteration in the effective length of a telescope is practically discovered by the adjustment of the eye-piece for distinct vision, which is necessarily different at different distances from the object viewed. But we have shewn, that the scales of Troughton's and of Dollond's micrometers will vary with the variable powers of even the same telescope, and therefore will require a correction for each variety of power, or, in other words, for each variety of terrestrial distance. The determination of these varying corrections, therefore, is essential to the accuracy of the measures taken by a micrometer in all cases, where the incident rays of light come diverging from objects placed at moderate distances. If we put f for the solar or principal focus of the object-glass of any telescope, and d for the distance of an object from the said object-glass when used, the addition to the length of the solar focus, which we will call e , according to the

laws of *dioptrics*, may be found by this theorem, $\frac{f^2}{d-f} = e$;

that is, the square of the solar focus, divided by the distance in the same measure, when diminished by one focal distance, will be the elongation, or excess of the lengthened focus over the solar focus; then as the powers are to each other respectively as the focal lengths, with the same eye-piece, we shall have $f : f + e :: \text{true angle} : \text{measured or apparent angle}$; and conversely, as $f + e : f :: \text{apparent}$

angle : true angle. For instance, let it be required to ascertain what is the necessary correction for an angle, measured by a telescope of 63.5 inches focus, that is subtended by one yard at a hundred yards distance from the object-glass. By a simple case in plain trigonometry, the true angle subtended by a yard, at a hundred yards distance, is $34' 59''.4$, or $34'.99$; and 63.5 inches are 1.764, when reduced into the denomination of yards and decimal parts; then

$$\frac{1.764 \times 1.764}{100 - 1.764} = \frac{3.111696}{98.236} = 0.03167 = e, \text{ the increased}$$

length of the focus; and $\frac{1.764 + 0.03167 \times 34'.99}{1.704} =$

$35'.618$, or $35' 37''.08$ will be the measured angle, therefore $35' 37''.08 - 34' 59''.4 = 37''.68$ is the correction to be added to the true angle, in order to obtain the apparent angle, that would have been the true angle also, if the focus of the object-glass had remained unaltered at the distance of 100 yards. But it is the correction answering to the apparent or measured angle that we want, and the determination of this requires a transposition which is operose, and therefore objectionable in practice; on which account we recommend each surveyor, military tactician, and leveller, who is disposed to avail himself of the use of a micrometrical telescope, for shortening his labours, to use tables adapted to the focal length of his own telescope, which may give by inspection the correction proper in all cases for reducing the apparent angle into the true one, and *vice versa*. Tables III. and IV. which are subjoined, were computed for this purpose, from the theorem just exemplified, and are adapted for a telescope of 63.5 inches focal length, to which we have added Table V., as a general table for finding the distance, in yards and decimal parts, corresponding to any angle, from $1'$ to $30' 59''$ inclusively; even to the accuracy of a single second, when that angle is subtended by an exact yard. The labour of constructing these tables has been considerable, but the facility and accuracy with which they give the desired results, has amply repaid the computer, and, it is presumed, will be a recommendation to the notice of our scientific readers, to whom their application may in many cases be found useful.

TELESCOPE.

TELESCOPE.

Construction and Use of the Tables.—We have already explained the construction and use of Tables I. and II., which are required to be adapted to the particular telescope with which any given micrometer is used; and we have also explained how the value of a single division, or turn of a screw, is ascertained by means of the sun's diameter: but this method gives a derivative rather than an original independent value to the micrometrical scale; for if the sun's diameter be not truly given in the Nautical Almanac (and the late Dr. Maskelyne had reason to alter it in the latest years of his life), the error of this measure will be introduced into the scale derived from it; Table III. is therefore inserted, as affording the ready means of obtaining an independent scale from actual terrestrial measurement. We have already shewn how the table of corrections is constructed in this table; and the reader will have no difficulty in taking out the proper numbers, as corrections to be added to the true angle, in order to convert it into the apparent or measured angle, if he be careful to take the minutes of the given angle from the left-hand vertical column, and the seconds from the horizontal line at the top; for in every instance, the meeting of the two columns will contain the additive quantity that is to be applied to the true angle, in order to obtain what the telescope will give when the value of its scale is once duly assigned. For instance, suppose the true angle $14' 20''$, where $14'$ is taken at the side, and $20''$ at the top, the junction of the two columns gives $+ 6''.28$, which shews that this quantity must be added to $14' 20''$, the true angle, to make $14' 26''.28$, the apparent angle, as measured by a telescope of 63.5 inches focal length. If now this angle, reduced into seconds, be divided by the turns of the screw, or divisions on any scale used as a micrometrical scale, the quotient will be the value in seconds of one turn, or division, as the case may be, provided the angle in question be that which a true yard actually subtends at a known distance. For example, when a yard of 36 exact inches was erected at the distance of 190.08 yards, the micrometer of Troughton, attached to Tully's 63.5 inch telescope, measured it by 34.78 revolutions of its screw; and by Table V. the true angle, read as in Table III. at the side and top, corresponding to this distance, is $18' 0''$; the additive quantity belonging to this angle, as taken from Table III., is $+ 9''.89$; and therefore the apparent angle, if measured by the said telescope, would be $18' 9''.89$; therefore $\frac{18' 9''.89}{34.78} = 31''.33$ is the value of

one revolution of the screw, which is very nearly the same as was determined from the sun, and before tabulated. This coincidence of the celestial and terrestrial measures affords a convincing proof that the scale has been duly appreciated.

We have said, that this table of corrections, and also the following one, which we shall explain presently, are computed exclusively for a telescope of 63.5 inches focus, being that which is represented, with a Troughton's micrometer attached, in fig. 6. of Plate XXIX.; and that each different telescope ought to have its own tables of corrections corresponding to its focal length, which limitation is required by the theorem on which we have grounded our calculations. But as the distance, which is the varying term, is the same for all telescopes, we find that in practice the corrections of any other telescope will be so nearly proportionate to their respective focal lengths, that they may be taken exactly as such, without any sensible error; that is, the error arising from the table of corrections will be always as small as the error of observation in ordinary telescopes, unless the distance be very small, and its correction consequently great. On this account, Table III., and also Table IV., which, it will be

seen, is derived from it, like Table V., may be considered as general tables, admitting of proportional parts of their whole corrections to be taken as suitable corrections for telescopes of other dimensions. This consideration is of great importance, with respect to the general utility of our tables of correction; and therefore the reader shall not depend solely on the authority of our bare assertion. We have already computed the correction for a telescope of 63.5 inches focal length, to be added when the true angle is $34' 59''.4$, or distance 100 yards, and found it $37''.68$; let us see what it will be with the same data, when the telescope has just one half of the said focal length: here we have $\frac{1.764}{2} = .882$ of a yard for the focal length; then $.882 \times .882 = .77924 = \frac{.77924}{99.118} = .00785 = e$, the elongation of the focus, and $\frac{.882 \times .00785 \times 34'.99}{.882} = 35'.3$, or $35' 18''$

for the apparent angle, from which, if we subtract $34' 59''.4$, the true angle, the difference $18''.6$ will be the corresponding correction, which differs only a quarter of a second from $\frac{37''.68}{2}$, or half the correction of the telescope of

double dimensions. Beyond 100 yards distance, the error, small as it is, will continue to diminish as the distance increases, and a smaller distance will seldom require to be measured in this way. The accuracy of this conclusion has been still farther corroborated by actual experiment: a graduated staff was placed erect at a distance, by measurement of a Troughton's chain of five-foot links, of 261.9 yards, and the two telescopes of 63.5 and 45.75 inches focal length, were tried against each other thus; a yard by the first was found, with Troughton's micrometer, to be equal to 25.33 turns; and by the second, with the same instrument, to be 18.19; the true angle belonging to this distance by Table V. is $13' 7''.54$; and the correction for the larger telescope by Table III. $+ 5''.25$; therefore, taking $\frac{45.75}{63.5}$ or .72 of $5''.25 = 3''.8$ for the correction of the smaller telescope, we have the following values of the respective scales; viz. $\frac{13' 7''.54 + 5''.25}{25.33} = 31''.2984$, &c. and

$$\frac{13' 7''.54 + 3''.8}{18.19} = 43''.504, \text{ which values accord very}$$

nearly with those that had been previously determined by a series of solar measures, and the latter of them exactly, as far as to the third place in the decimal figures.

Table IV. is the table to be used with Table V. for finding, first the true angle from the apparent one, and then the true distance at once from this true angle: its corrections are arranged somewhat differently from those in Table III., and have an opposite sign, but are borrowed from Table III. in such way, that by means of a little transposition, the terms of one may be converted into those of the other; as, for example, at the apparent angle $18' 40''$, in Table IV., the correction is $- 10''.4$, and the true angle consequently $18' 29''.6$; and at $18' 30''$, the nearest numbers for the true angle in Table III., the correction is $+ 10''.44$, which makes its corresponding apparent angle $18' 40''.44$. In the former of these two tables, the correction is calculated to the hundredth part of a second; it being that from which the scale has its value appreciated; but in the latter, it was deemed convenient to leave out the hundredth parts, as being

TELESCOPE.

being beyond the powers of the telescope, or rather of the human eye, when a single observation is taken.

Before Table V. was constructed, it was found by plane trigonometry, that one yard will subtend an angle of one minute at 3437.7 yards distance; and, as the distance decreases in the same ratio in which the angle increases, the table was made by a continual reduction of this number into halves, thirds, fourths, &c. as far as to 30', and all the intermediate seconds from 1' to 30', were inserted with their corresponding distances. For instance, at the true angle of 18' 30'', the true distance is 185.82 yards; it being always understood, that the measured angle is subtended by an exact yard placed at right angles to the line of sight, in either a vertical or horizontal position, and that the correction taken from Table IV. has been applied to the measured or apparent angle. If two yards should be used as the opposed object at a great distance, then *half* the angle only must be taken; but if half a yard only be used at small distances, then *double* the angle will be proper; and should the distance be within 110.95 yards, the smallest distance contained in the table; in which case the angle will exceed 30': the distance belong-

ing to *half* the angle will always be *double* the distance required. Suppose the angle 33'; then half of this is 16' 30'', and the double number 208.34; consequently 104.17 yards will be the corresponding distance; and thus the table will extend to any short distance, by taking a given portion of the measured angle, when reduced to the true one, and by using the same portion of the corresponding distance, provided the angle do not exceed 60', which is the limit of Table IV., and which is as much as a telescope magnifying only 30 times will usually take into the field of view.

In order to exemplify the use of these new tables, and at the same time to prove their accuracy, we obtained from Mr. Troughton a couple of staves, having each a sliding yard of brass, cut into notches for decimal divisions of a yard, which are capable of being seen at a distance, with an apparatus for placing them perpendicular in any given situation: on the 8th of October 1816, one of these staves was fixed in a perpendicular position at an unknown distance on level ground, and the following measures were taken of the angle subtended by a yard, by Troughton's micrometer successively adapted to each of the four telescopes, thus:

With telescope	30.15 in.	24.59 revol.	= 27	2.9 (by Tables I. and II.)	= 10.4 (by Table IV.)	= 26	52.5	
	45.75 in.	37.53 revol.	= 27	10.5	= 15.6	= 26	54.9	
	63.5 in.	52.25 revol.	= 27	15.43	= 21.85	= 26	53.58	
	118.8 in.	98.52 revol.	= 27	35.1	= 41.0	= 26	54.1	
							4)	215.08

Average = 26 53.77

By Table V. the distance corresponding to this angle is 127.81 yards, and by measurement of a good chain, it was afterwards found to be $5.808 \times 22 = 127.776$ yards, the difference or error being only .034 of a yard, or something less than an inch and a half. During the observations, the sun was obscured by clouds, and the object viewed had no vibratory motion, which is a circumstance essential to be attended to.

With Dollond's divided object-glasses applied to the telescope of 45.75, the measure was 2 in. 11 div. 19 ver., or 1294 of the vernier, which, multiplied by 1".24, the solar

value of unity, gave the measured angle only 26' 44".56; but on examining the ratio in which the focus elongates at different distances, we found that the divergence of the rays was lessened so much, in passing through the divided object-glasses, before they entered the achromatic object-glasses, that the table of corrections would be of no use for this arrangement of two separate object-glasses.

On the 16th of the same month the graduated staff was erected at a greater unknown distance, and the following measures were taken by Troughton's micrometer, as before, *viz.*

With telescope	45.75 in.	27.59 revol.	= 20	0.1	- 8.6 (correction)	= 19	51.5
	63.5 in.	38.48 revol.	= 20	4.4	- 12	= 19	52.4

2)103.9

Average = 19 51.95

to which angle the corresponding distance by Table V. is 173.0 yards; and the subsequent measure by the chain accurately repeated was 172.92 yards, in which determination the error was .08 of a yard, or 2.88 inches only.

From these operations we are persuaded that a good telescope, with a Troughton's micrometer, will determine distances, by simple inspection, when within the eighth part of a mile, with more accuracy than is usually done by a surveyor's chain or measuring-wheel; and, consequently, if both a backward and forward view be taken from one station, situated near the middle of a line joining two graduated staves, a *quarter of a mile* may be so determined at *one station* in the space of two or three minutes after the station is taken. But it may be said, why not take a quarter of a mile at one sight, since the power of a good telescope will command a small object at this distance? To which we answer, that the error arising from distance

may be considered rather as a geometrical than an optical error: our experiments have convinced us that a small angle may be measured by Troughton's micrometer, when the thickness of the spider's line is allowed for, (*viz.* $\frac{1}{8}$ th of a turn of the screw in our micrometer,) so accurately, that the error of observation in favourable weather will seldom exceed *one second*; but the error in distance, corresponding to an error of one second in the measured angle, increases in the duplicate ratio of the distance, and consequently becomes too considerable to be admissible beyond a limited distance; for instance, at the distance of 220 yards, or the eighth of a mile, an error of 1" in the angle subtended by a yard produces only an error of 0.23 of a yard in distance; but at 440 yards, or a quarter of a mile, the error in distance corresponding to the same error in the angle is 0.92; that is, at twice the distance the geometrical error is four times augmented; which circumstance limits

limits the distance at which micrometrical measurements in longimetry can be usefully employed at one station. What may be called the *optical error*, or that which arises from want of parallelism in the rays of light on entering the object-glass, and is allowed for in our fourth table, on the contrary, decreases with an increase of distance, and very nearly in a sub-duplicate ratio; so that the correction arising out of this optical error becomes insensible at no very great distance in telescopes of ordinary dimensions: for instance, at 220 yards, or its angle $15' 38''$, the correction is $- 7''.4$ by our Table IV.; but at 440, or its angle $7' 49''$, the correction diminishes to $1''.9$, or nearly a fourth of the former at double the distance. Hence there is a peculiar distance at which every separate telescope will have its optical error or correction reduced to $1''$, or quantity of probable error of observation, beyond which distance the tabulated corrections may be disregarded in ordinary operations. With the telescope of 63.5 inches focus, the correction will be less than $1''$ at 590 yards distance; with that of 45.75 inches, at 537; and with that of 30.15 inches, at 430, the distance continuing to diminish with the diminishing length of the focus of each object-glass, but not in the same ratio; consequently, when the telescope is very short, and its power small, the optical error may be altogether disregarded, wherever such telescope can be of any real use; because, in all probability, this error will be less than the error of observation arising from want of power.

TELESCOPE Shell, in *Conchology*, the name of a species of *turbo*, with plane, striated, and numerous spires.

TELESCOPICAL STARS, such as are not visible to the naked eye, but discoverable only by the help of a telescope. See **STAR**.

All stars less than that of the sixth magnitude are telescopic to a middling eye.

TELESE, in *Geography*, a town of Naples, in Lavora, the see of a bishop, who resides at Cerreto; 18 miles E.N.E. of Capua. N. lat. $41^{\circ} 12'$. E. long. $14^{\circ} 32'$.

TELESIA, or **TELESSIA**, in *Ancient Geography*, a town of Italy, in Samnium.

TELESIA, in *Mineralogy*. See **CORUNDUM**.

TELESIO, **BERNARDINO**, in *Biography*, a modern philosopher, the descendant of an illustrious family at Cosenza, in Naples, was born in the year 1508 or 1509. Having received the early part of his education under an uncle at Milan, he accompanied him to Rome in 1525, and shared in the calamities which attended the sack and pillage of that city. At Padua, whither he afterwards removed, he applied himself with diligence to the study of mathematics and philosophy. Returning again to Rome, he formed an intimate acquaintance with several persons of distinguished character, and so much ingratiated himself with pope Pius IV. that he was offered the archbishopric of Cosenza, which he declined for himself and obtained for his brother. From Rome he retired to his native country, where he married in advanced age, and for a short time became professor of philosophy in the university of Naples. However, the place of his more constant residence was Cosenza, and here he established an academy called Cofentina. He passed the remainder of his life under the patronage of several persons of distinction, particularly Ferdinand, duke of Nocera; but afflicted by the assassination of one of his sons, and by the calumnies circulated against his school of philosophy, he terminated his life in the year 1588. Telesio distinguished himself by his opposition to the physics of Aristotle, and employed mathematical principles in explaining the laws of nature. These were first divulged in a work printed at Rome in 1565, entitled "De Rerum Natura juxta propria

principia, Lib. II." and enlarged to nine books in an edition printed at Naples in 1586. The same system was maintained in other treatises, under the titles of "De his quæ in Aere fiunt, et de Terræ Motibus;" "De Mari;" "De Colorum Genere," &c. His system was in its essence the doctrine of Parmenides, who taught, that the first principles in nature, by means of which all natural phenomena are produced, are cold and heat. (See **PARMENIDES** and **ELEATIC**.) Telesio's theory is thus developed: "Matter, which is in itself incapable of action, and admits neither of increase nor diminution, is acted upon by two contrary incorporeal principles, heat and cold. From the perpetual opposition of these, arise the several forms of nature: the prevalence of cold in the lower regions producing the earth and terrestrial bodies, and that of heat in the superior regions, the heavens and celestial bodies. All the changes of natural bodies are owing to this conflict; and according to the degree in which each principle prevails, are the different degrees of density, resistance, capacity, moisture, dryness, &c. which are found in different substances." This system is founded on the fanciful conversion of mere attributes and properties into substantial principles. For lord Bacon observes, that Telesio, no less than Plato and Aristotle, places abstract notions at the basis of his system, and produces his world of real beings from non-entities. This eminent philosopher, however, characterises him as a lover of truth and a benefactor to science; and one who prepared the way for subsequent improvements. After his death, his writings, as containing "innovations," were put into the Index Expurgatorius of the Inquisition. His philosophy, nevertheless, had many advocates, among whom was Campanella; and his works were republished at Venice, in 1590, by Antonio Persio, who wrote a compendium of his philosophy in the vernacular tongue. Telesio's style was more polished than that of other philosophers of his time; and he intermixed some Latin verses of considerable eloquence. Brucker by Enfield.

TELESPHORUS, in *Mythology*, a deity invoked by the Greeks for health, together with Esculapius and Hygeia. The figures of these three divinities occur on several medals; and on some we have Telesphorus with Esculapius alone, and on others with Hygeia.

The figure of Telesphorus is invariably the same, viz. that of an infant clothed with a sort of cloak without sleeves, which enfolds its arms, descends below the knees, and has a kind of hood or cowl covering its head.

Montfaucon has given a particular description of this deity, the worship of which is supposed to have passed from Epidaurus to Rome, with that of Esculapius.

TELETÆ, among the *Ancients*, were solemn rites performed in honour of Isis.

TELETZKOI-OZERO, in *Geography*. See **ALTIN**.

TELETZKOI Mountain, deriving its name from the lake Teletzkoi-ozero, 'one of the greatest eminences of the Altay mountains (see **ALTAI**), and from which the river Oby issues. It forms, with its lofty summits, the boundary between Siberia and the Soongarey, strikes its powerful ridges down between the lake and the Katunia; and after having turned round the east side and the lake, unites with the Kunetzkoï mountains. This division is one of the greatest, but at the same time the coldest and most inaccessible, of all the Altaian ore-mountains; hence it is, that its quality and contents are little known. This, however, is certain, that very powerful granite and porphyry mountains are in its range, and that the earth near and upon it yields jasper, flint breccia, hornschistus, white (probably saline) chalk-stone, coloured marble, black schistus, marle, sand-stone, and in these

these there are iron, argenteous copper, and lead ores, naphtha, asphaltus, &c. The mountains to the right of the Katunia seem to be particularly rich in ores.

TELEUTES, or **TELENGUTES**, a tribe of Tartars, who are supposed to have derived their name from the lake Telegul in the Altay mountains. They are also denominated by the Russians the white Kalmucks, because they formerly lived among the Soongarians. Abulgasi reckons them among the Mongolian races; but as their speech is manifestly a corrupt Tartarian, their origin may more consistently be derived from that nation. In the year 1609 they did homage for the first time to the Russian empire; but it was not till towards the middle of the 17th century, when some stems of them removed higher up the Tom, that they became properly subjects of Russia: the greater part of them, however, remained with the Kalmucks. The former dwelt partly in the Tomskoi district of the Tobolskian, partly in the Kufnetskian circle of the government of Kolhyvan; and their number is so small, that they only reckon about 500 males.

TELS, a town of the county of Tyrol, near the Inn; 15 miles W.S.W. of Innsbruck.

TELGEN, a town of Sweden, in Sudermanland, on the lake Mæler; 15 miles S.W. of Stockholm.

TELGET, a town of Germany, in the bishopric of Munster; 5 miles E.S.E. of Munster.

TELGHIOURAN, a town of Asiatic Turkey, in the government of Diarbekir; 30 miles S. of Diarbekir.

TELHEIM, a town of the duchy of Wurzburg; 7 miles S.S.W. of Schweinfurt.

TELHEIRO, a town of Portugal, in the province of Beira; 6 miles S.W. of Pinhel.

TELICA, a volcano of Mexico, near Tecoaatepecque.

TELICARDIOS, in *Natural History*, the name given by some authors to a stone found in the shape of a heart. It owes this figure to its having been found in the shell of some large bivalve of the cockle kind; and is more usually known among authors under the name of bucardites.

TELIGUL, or **TELEGUL**, in *Geography*, a lake of Russia, in the Altay mountains, about 120 miles in circumference. N. lat. 43° 12'. E. long. 64° 14'.

TELIPHANO, in *Botany*, a name used by some authors for the doricum, or leopard's bane.

TELL, **WILLIAM**, in *Biography*, a celebrated Swiss, was an inhabitant of middle rank of Burgeln, in the canton of Uri, and son-in-law of Walter Furst. In 1307 he engaged in the conspiracy against the Austrian tyranny. Gesler, the German bailiff, suspecting a plot, artfully contrived a scheme for ascertaining the extent of submission to the Austrian yoke. Accordingly he set up a hat upon a pole, and commanded that obedience should be paid to it. Tell resisted the command; and, as tradition reports, the arbitrary bailiff ordered him to shoot with an arrow at an apple placed on the head of his son. He cleft the apple without hurting the child; and being observed to have another arrow, he was interrogated what he intended to do with it. He unhesitatingly replied, that if he had wounded his son, the other shaft should have been directed to the bailiff's heart. This bold declaration caused him to be imprisoned. Of this fact there is no doubt; though the incident of the arrow and apple may be fabulous, as it is applied by Saxo Grammaticus to a Dane at an earlier period. The bailiff took Tell with him across the lake of Lucern, designing to convey him to another canton. In the passage, a storm arose; and the vessel being in danger, the fetters of Tell who was known to be a skilful boatman, were taken off, and the helm was committed to his hands. Availing himself of this circumstance, he steered to a rock and made his escape. Gesler on landing met with his fate from an arrow

of Tell, who afterwards retired to Stauffacher in the canton of Schweitz; and on the following new-year's day, all the Austrian governors were seized and dismissed from the country; and this circumstance is said to be the commencement of Swiss freedom. Tell's death is supposed to have been occasioned by an inundation at Burgeln in the year 1354. His grateful countrymen erected a rude chapel to his honour on the spot where he resided, and another upon the rock on which he landed. His posterity, however, sunk into oblivion, without any permanent distinction; the last who bore his name died in 1684, and the last of the female line in 1720. Coxe. Muller. Gen. Biog.

TELLA PASHNUM, in *Natural History*, a name given by the people of the East Indies to a kind of white arsenic, or rat's-bane, found native among them.

It is well known to be a fatal poison, and used to destroy vermin. It lies in the cliffs of rivers among strata of stone in large white irregular lumps; when held to the fire, it emits copious fumes, smelling strongly of garlic and sulphur, but it does not readily melt or run.

TELLA Sagrum, a name given by the natives of the East Indies to a kind of earth which they use externally to dry up ulcers, and internally in cases of coughs and colds. It is of the nature of the finer clays, and is found at the bottom of some of their rivers.

TELLEGROD, in *Geography*, a morass on the borders of Norway and Lapland, which cannot be crossed without much apprehension of danger. During winter it is frozen to the depth of several yards, and does not thaw till the summer is far advanced. The surface may appear dry and solid, but as the heat still penetrates downwards, the icy floor which supports it, softening and melting, bends and trembles under the shock of pressure, and at last gives way, so that horses, carriages, and passengers—all sink into the abyss. Near the mouth of the Fiord, or firth, a bed of clay-marle is seen distinctly mixed with small shells. Appearances of a like kind occur along the southern shores of Norway, and the fact is the more remarkable, since no fossil shells have been ever found in the interior of the country. This marle, however, is only a local formation, and rests on the fundamental gneiss.

TELLER, an officer in the exchequer, of whom there are four: whose business is to receive all monies due to the crown, and thereupon to throw down a bill through a pipe into the tally-court, where it is received by the auditor's clerks, who attend there to write the words of the said bill upon a tally, and then deliver it to be entered by the clerk of the pells, or his clerk.

The tally is then split or cloven by the two deputy chamberlains, who have their seals; and while the senior deputy reads the one part, the junior examines the other part with the other two clerks.

The tellers' places are in the king's gift, and they have besides their chief clerk or deputy, and other clerks for the dispatch of business.

TELLER, MARCUS, in *Biography*, a priest and musical composer in the church of St. Gervais, in Maestricht, published in 1726, his first work at Augsburg, under the title of "Musica sacra stylo plane Italico et Chromatico pro Compositionis amatoribus, complectens IX Motetta brevia de Tempore, et II Missas solemnes, &c." His second work was posthumous, and published likewise under the solemn title of "Musica sacra," consisting of four masses and four motets, for four voices, two violins, tenor, bassoon, and a basso continuo, or figured base.

TELLER, FLOBIAN, an eminent dramatic composer of the music of grand opera ballets. In 1763 he composed music for the ballet of Orpheus and Euridice, for the

duke of Wurtemberg's theatre at Stuttgart; and the year after, for his highness's birth-day, that of Noverre's grand ballet called "The Triumph of Neptune." The ballet music of this composer superfed that of Lulli and Rameau at Paris; and in our opera, the music of the *ballets historiques*, and chaconnes danced by Mad. Heinel and Veftris, was chiefly the production of Teller.

TELLES, in *Geography*, a fea-port of Africa, in the kingdom of Fez, on the coast of the Mediterranean; the harbour is small but safe, and the bottom good; 120 miles E.S.E. of Tangiers.

TELLICHERY, a city of Hindooftan, on the coast of Malabar, belonging to the English, and defended by lines. It was long besieged by the forces of Hyder Ali; but in the year 1782 the troops were defeated, the camp taken, and the general wounded and made prisoner by the British, under the command of major Abingdon. The situation of the town is beautiful and healthy: pepper is the great article of trade, and cardamoms; 48 miles N.N.W. of Calicut. N. lat. $11^{\circ} 15'$. E. long. $75^{\circ} 20'$.

TELLICO, a town of the state of Tennessee, with a block-house; 50 miles S.W. of Knoxville. N. lat. $35^{\circ} 37'$. E. long. $84^{\circ} 18'$.

TELLIER, MICHAEL, in *Biography*, a distinguished Jesuit, was born in 1643, near Pire, in Lower Normandy. He studied at the Jesuits' college at Caen, and entered into the society at eighteen years of age. Having for some time taught the schools, he was directed by his superiors to prepare an edition of Quintus Curtius, "in usum Delphini," which was printed in 1678. He was afterwards selected, with other eminent brethren, to establish at the Jesuits' college at Paris a society of learned men, who might retrieve the honour of the body; but his views were directed to other objects, and he became a zealous controversialist in the subjects of dispute between the Jesuits and other orders. Accordingly, in 1687, he published "Defense des Nouveaux Chretiens et des Missionnaires de la Chine, du Japon, et des Indes," which was attacked by Arnauld in his "Morale Pratique," and was announced to the holy office: and sentence of condemnation was averted by a promise that Tellier should come to Rome, and make alterations in his work. This prepared the way for numerous publications; in consequence of which Tellier gained increasing reputation, and was advanced to the offices of revisor, rector, and provincial. Upon the death of F. la Chaise in 1709, he was chosen, in competition with another candidate, and in consequence of an assumed air of modesty, to succeed him as confessor to the king. But whatever modesty he might assume to serve a present purpose, he had little true humility. Ardent, unsympathizing, and despotic, he was hated by his brethren over whom he tyrannized, in the most unwarrantable manner. Fontenelle, who well knew his disposition and character, hearing of his appointment, said, "The Jansenists have sinned." His first act was the demolition of the famous house of Port Royal, which he razed to its foundation; he then forced upon the nation and the magistrates the bull Unigenitus; and he proceeded with such violence, that the Jesuits themselves said, "Father le Tellier drives us at such a rate that he will overturn us." Tellier's conduct brought disgrace on the society, and was ultimately the chief occasion of its abolition. On the death of Louis XIV. he was exiled, first to Amiens, and afterwards to La Flèche, where he died in 1719, at the age of seventy-six. The morals of Tellier were regular; and though some persons suspected him of hypocrisy, others have with greater probability believed, that he was actuated by real zeal for the principles which he had adopted. He was a man of literature, wrote many works, and was a member of

the Academy of Belles Lettres. Nouv. Dict. D'Alenbert's Hist. of the Jesuits.

TELLIGT, in *Geography*, a town of Germany, in the bishopric of Munster, with a rich abbey, on the Ems; 3 miles from Munster.

TELLIGUO MOUNTAINS, or *Iron Mountains*. See *IRON Mountains*.

TELLINA, in the Linnæan system of *Conchology*, a distinct genus of the class of Vermes, and order of Testacea. For the characters of this genus, see *CONCHIOLOGY*. Gmelin enumerates ninety-one species.

TELLINGANA, in *Geography*, a province of Hindooftan, now called Golconda.

TELLINGSTEDE, a town of the duchy of Holstein; 11 miles S.E. of Lunden.

TELLIPOLI, a town on the N. coast of the island of Ceylon; 9 miles N. of Jaffnapatam.

TELLO, a town on the W. coast of the island of Celebes, and capital of a small kingdom, once united to Macassar. S. lat. 5° . E. long. $120^{\circ} 2'$.—Also, a town on the W. coast of the island of Lombeck. S. lat. $8^{\circ} 24'$. E. long. $115^{\circ} 45'$.

TELLO *Langue*, a town on the W. coast of Sumatra. N. lat. $0^{\circ} 51'$. E. long. $98^{\circ} 21'$.

TELLO *Point*, a cape on the W. coast of Sumatra. S. lat. $1^{\circ} 50'$. E. long. $100^{\circ} 31'$.

TELLONIUM. See *THELONIUM*.

TELLONUM, in *Ancient Geography*, a place of Gaul, in Aquitania, near the sea-coast, S.E. of Burdigala.

TELOW, in *Geography*, a town of Brandenburg, in the Middle Mark, famous for its turnips; 10 miles S. of Berlin. N. lat. $52^{\circ} 23'$. E. long. $13^{\circ} 15'$.

TELLUDOPIN, a town of the island of Celebes, in Bugge's bay. S. lat. $2^{\circ} 35'$.

TELLURE, in *Agriculture*. See *TILLER*.

TELLURIUM, in *Mineralogy*, a metal discovered by Klaproth, combined with gold and silver, in the ores from the bannat of Temeswar, and in the Farzebay mountains in Transylvania. The ores of this metal are denominated *native tellurium*, *graphic tellurium*, *yellow tellurium*, and *black tellurium ore*.

Native Tellurium; *Gedigen Sylvan*, Werner.—The colour is intermediate between tin and silver white, and sometimes inclines to steel-grey. This ore is found massive and disseminated; it is said sometimes to occur crystallized in four-sided prisms; it occurs also in small granular concretions. It yields to the knife, and is rather brittle. The specific gravity, according to Klaproth, is 6.15. Before the blow-pipe, native tellurium melts easily before ignition; it burns with a greenish flame, and is entirely volatilized in a dense white vapour, which has the acrid odour of horse-radish. When exposed to a low heat, it is converted into a yellowish or blackish oxyd: by an increase of temperature it forms a dark brown or black glass, in which gold grains are interspersed: at a still higher heat the oxyd is entirely volatilized. The constituent parts are, according to Klaproth,

Tellurium	-	-	-	-	92.55
Iron	-	-	-	-	7.20
Gold	-	-	-	-	.25

The proportion of gold is however variable. In one variety of native tellurium, Klaproth found 9 parts in the 100 of gold. Native tellurium occurs in veins with quartz and lithomarge. It is known, in the older works on mineralogy, by the name of *aurum problematicum*, *aurum paradoxicum*, and *white gold ore*.

Graphic Tellurium; *Tellure natif graphique*, Haüy.—This is worked as an ore of gold at Ossenbanya, in Transylvania,

TELLURIUM.

where it has hitherto only been found. It is so called, from the particular appearance formed by the aggregation of the crystals; it occurs in veins in porphyry. The colour of graphic tellurium is steel-grey, which is sometimes variously tarnished by exposure to the air: it is also found white, yellow, or lead-grey. It has a shining metallic lustre. It occurs massive, disseminated in leaves, and crystallized in small compressed hexahedral prisms, either with or without tetrahedral summits, and generally arranged in rows on the surface of quartz. There are frequently other prisms attached to the extremities of the former, at right angles with them, giving the whole row an appearance of Perieopolitan characters. The planes of the crystals are smooth. "The massive variety, which is very rare, occurs in granular distinct concretions." (Jamieson's Min.) It is soft, brittle, and frangible, and yields a lead-grey streak. The specific gravity is 5.723. Before the blow-pipe it burns with a green flame, and is volatilized. The constituent parts, according to Klaproth, are

Tellurium	-	-	-	-	-	60
Gold	-	-	-	-	-	30
Silver	-	-	-	-	-	10

Yellow Tellurium Ore.—The colour of this ore is silver-white, passing into yellowish or brass-white and grey. It occurs in grains, and in minute compressed four-sided prisms, with a lamellar structure and bright metallic lustre: it also occurs massive and reticulated: it is soft and somewhat sectile: the specific gravity is 10.878. The constituent parts, according to Klaproth, are

Tellurium	-	-	-	-	-	44.75
Gold	-	-	-	-	-	26.75
Lead	-	-	-	-	-	19.5
Silver	-	-	-	-	-	8.5
Sulphur	-	-	-	-	-	5

This ore, which is worked for the gold and silver it contains, has hitherto been found only at Nagyag, in Transylvania. It occurs in small irregular veins in porphyry. The most frequent vein-stones are brown spar and quartz: it is sometimes associated with red manganese ore, sulphuret of manganese, native arsenic, plumose antimony, and native gold.

Black Tellurium Ore; Nagyagerz, Werner.—The colour of this ore is between iron-black and dark lead-grey. It occurs massive and in leaves, and also crystallized, in the following forms; oblique four-sided tables, rectangular four-sided tables, six and eight-sided tables, and in acute octohedrons acuminate at the summit. It has a splendid metallic lustre, a more or less curved lamellar structure, with joints on cleavage in one direction. It yields easily to the knife, and is sectile: the thin laminæ are flexible: it stains slightly when rubbed in the fingers. The specific gravity is 8.919. This ore melts very easily before the blow-pipe; the sulphur and tellurium are volatilized; a blackish round-coloured globule remains, which, on being melted with borax, yields a globule which consists of gold alloyed with silver; the slag which remains tinges borax violet-blue. Its constituent parts, according to Klaproth, are

Tellurium	-	-	-	-	-	32.2
Lead	-	-	-	-	-	54.0
Gold	-	-	-	-	-	9.0
Silver	-	-	-	-	-	0.5
Copper	-	-	-	-	-	1.3
Sulphur	-	-	-	-	-	3.0

This ore is found associated with the preceding ore of tellurium. An ore of tellurium has lately been discovered in Norway by Esmark. An account of the mines where tellurium is obtained, was published by M. Stutz in the new *Memoirs of the Society of Naturalists at Berlin*, vol. ii,

1799, and by Esmark, entitled "An Account of a Mineralogical Journey through Hungary, Transylvania, and the Bannat," in the *Neuen Bergmannischen Journal*, vols. i. and ii. Dr. Clarke, in the 4th vol. of his *Travels*, has also recently given a description of the tellurium mines, from which we shall briefly extract the most interesting particulars at the close of the present article.

Analysis of the Ores of Tellurium.—These ores are worked for the gold and silver they contain; and the tellurium with which they are combined being extremely volatile at a low degree of heat, this metal was lost in the process of extraction, and was for a long time supposed to be antimony. Muller first suspected that it was a new metal. Bergmann made several experiments upon it, but left the question undecided.

Klaproth, in 1798, read an account of the discovery of this new metal in the public sitting of the Royal Academy of Sciences at Berlin.

The process of extracting the metal from native tellurium is as follows. Six parts of muriatic acid are poured on the crude ore, which has been previously separated as much as possible from its matrix, and mechanically divided. Heat is applied, and three parts of nitric acid are added by degrees. A violent effervescence takes place. By this process the metallic portion of the ore is dissolved, leaving the matrix, which is principally quartz, behind. In the next place, the filtered solution is carefully diluted with as much water as it will bear without being rendered turbid. Caustic potash or soda is added, until the precipitate which is first produced disappears, and only a dark-brown slimy residue remains.

Decant the solution, setting the residuum apart for subsequent examination: it consists of iron and gold. To the alkaline solution add muriatic acid, until it be saturated, most accurately observing the point of saturation. A copious white precipitate ensues, which in a raised temperature falls to the bottom of the vessel in the form of a heavy powder. It is then collected, and washed with equal parts of water and spirits of wine, and dried in a gentle warmth. This is the oxyd of tellurium. To reduce it to a metallic form, it should be heated in a small glass retort along with one-twelfth of its weight of charcoal, or it may be previously moistened with oil. Adapt a receiver to the retort, and let heat be applied till the powder be brought to a state of ignition. Small metallic drops will be seen lining the upper part of the retort, which fall down separately, and are succeeded by others. On refrigeration, the reduced metal (excepting some few metallic drops on the shoulder of the retort) is found fused, with a clean splendid surface, which is most frequently crystalline. At the moment the reduction takes place, a quantity of carbonic-acid gas is suddenly generated, carrying along with it some particles of the mixture, which it deposits in the receiver. The other ores of tellurium being worked as gold ore; for their analysis, see GOLD.

Tellurium in the pure reguline state was first obtained by Klaproth, who has given the following description of it: it is of a tin-white colour, verging to lead-grey; it has a very high metallic splendour, and a foliated structure; the surfaces of the fragments are very brilliant. When cooling slowly after fusion, it assumes a crystalline surface. It is very brittle, and easily reduced to powder. Among all the known fusible metals, except the metalline alkalies or earths, tellurium possesses the least specific gravity, being only 6.185.

Tellurium melts sooner than antimony, when exposed to the same degree of heat, but later than lead. It inflames upon charcoal before the blow-pipe with a violence resembling detonation, and with a vivid light-blue flame, which on the edges has a greenish tinge. By the continued action of the blow-pipe, it is entirely dissipated in a greyish-white vapour, and emits a smell like that of scraped radish.

Tellurium amalgamates very imperfectly with mercury, even when heat is applied. It combines with sulphur in equal proportions when fused in a gentle heat, and forms a lead-coloured striated substance. With nitric acid, tellurium yields a limpid colourless solution, which is not rendered turbid by water. In the concentrated solution, very light, slender, needle-shaped crystals are formed, which commonly assume a dendritical arrangement. Muriatic acid, on the addition of a little nitric acid, affords a similar clear solution of this metal. This saturated solution is decomposed by the mere addition of water, which throws down a white powder, but this is again dissolved on adding more water.

The powder thrown down is not a pure oxyd of tellurium, as it is combined with a small quantity of muriatic acid. If tellurium be exposed to one hundred times its weight of concentrated sulphuric acid, the acid gradually acquires a tinge of a fine deep amethystine red. This colour is destroyed by the addition of water, and by heat.

Carbonated and pure alkalies precipitate tellurium in the form of a white oxyd, combined with water or an hydrate. This is redissolved by an excess of alkali. Alkaline sulphurets throw down a dark-brown or blackish precipitate. Tincture of galls produces a flocculent yellow precipitate. The solutions of this metal in acids are not decomposed by prussiate of potash, a property which tellurium possesses in common with gold, platina, iridium, osmium, rhodium, and antimony. Zinc and iron precipitate tellurium from its solution in acids, in the metallic state, in the shape of blackish flocculi, which acquire a metallic lustre by trituration. Phosphorus is gradually coated with metallic laminae in a muriatic solution of tellurium.

Oxyd of tellurium on charcoal is reduced with brisk effervescence, and afterwards volatilized; but if heated in a small glass retort it fuses, and on refrigeration exhibits a straw-yellow colour and a striated texture. Some of these properties of pure metallic tellurium are common to native tellurium. Since the first discovery of this metal by Klaproth, it has been further ascertained, that it combines with chlorine in the proportion of 100 parts of tellurium with 90.5 of chlorine. Tellurium forms two distinct compounds with hydrogen, the one of which is solid, and the other gaseous. The first is formed by making tellurium the negative surface in water in the Galvanic circuit; by this a brown powder is produced, which is a solid hydruret of tellurium. The second is formed by acting with dilute sulphuric acid upon the alloy of tellurium and potassium, by which a peculiar gas is produced, having a smell resembling that of sulphuretted hydrogen. It is absorbed by water, and a claret-coloured solution results, which by exposure to the air becomes brown, and deposits tellurium. After being washed with a small quantity of water, this gas does not affect vegetable blue colours. It burns with a blueish flame, depositing oxyd of tellurium, and unites with alkalies. It precipitates most metallic solutions, and is itself instantly decomposed by chlorine gas. It may be called telluretted hydrogen gas.

Tellurium is one of those metals whose oxyds possess the characters of acids, and form distinct classes of salts. The salts formed by a combination of a base with the oxyd of tellurium, are called by Berzelius *tellurets*.

Tellurium, according to Klaproth, combines with oxygen in the proportion of 100 parts of the metal with 20.5 of oxygen; but Berzelius determines the proportions to be 100 tellurium and 27.83 oxygen.

This metal has not hitherto been applied to any useful purpose in the arts, which may probably be attributed to its scarcity, and the comparative recentness of its discovery.

Tellurium Mines.—"The mine of Nagyag is distant about

15 miles from Deva, in the bannat of Temeswar: it is situated in the heights of the mountains, lying on the north side of the river Moros. After crossing the river, we began to climb these heights. The roads were not bad, but almost the whole journey to Nagyag was up a steep ascent. We were five hours, although drawn by four horses in a light car, before we reached the small town where the mine has been opened.

"As Transylvania is the only country in the whole world where tellurium has been discovered, our curiosity was greatly excited to view the Nagyag mine. At last the prospect opened upon us with great boldness of scenery quite among the summits of this mountainous region, and in a manner highly picturesque and striking. The situation of the mine was distinguished by an immense heap of discarded minerals thrown out in working it.

"The whole village of Nagyag has been undermined: the works are not only carried on upon a grand and extensive scale, but they are conducted with a degree of neatness, for which the Germans have long been famous in mining. Some specimens of tellurium are so exceedingly rich in gold, that in the sale of them for the crown, it is necessary to weigh them, and to estimate the price according to the quantity of gold they contain. This kind of ore is always kept locked up in private warehouses. The common ore lies exposed in heaps, at which the workmen are busily employed in preparing the ore for stamping.

"When the mine was first discovered, the mountains around it were covered with forests, which have since been cut down to supply the mines with timber. The discovery of the mine is thus related on the respectable authority of baron Boon, in his letter to professor Feber. 'A Wallachian, whose name was Armenian John, came to my father, then possessed of a rich silver mine at Cuertes, telling him, that as he constantly observed flames issuing from and playing upon a fissure in the Nagyag forest, he was of opinion that rich ore might be hid under ground. My father was fortunate enough to listen to the poor man's tale; and accordingly he drove a gallery in the ground which the Wallachian had pointed out. The works went on some years without success, and my father had resolved to give them up. However, he made a last drift towards the fissure, and there he discovered the black and lamellated gold ores, which were at first looked upon as iron glimmer, but proved, when assayed, to be, what they really are, rich gold ores.' Travels through the Bannat, Lond. 1799.

"Other veins were afterwards discovered running parallel to each other from north to south, and dipping from west to east. When Boon visited Nagyag, the mine had only been worked to the depth of 60 fathoms. Its depth is now 150 fathoms. The mountains are entirely composed of porphyry, covered with red clay or red slate and sandstone. The veins break off as soon as they reach the red slate. These veins contain with the ore, feldspar and fat quartz. There is also found here a very rich kind of ore, which is finely woven into the texture of a reddish feldspar. Among the rich ores, native silver occurs mixed with gold. Another variety is called by the miners *cotton ore*; it consists of little native silvery gold grains in tellurium, adhering to an argillaceous matrix. All the semi-metals at Nagyag are found, when carefully analysed, to contain gold. According to Boon, the tellurium mines in the course of 20 years yielded above 4,000,000 florins in gold and silver. At the time of our arrival it had been worked 60 years, and was equally productive."

TELLUS, TERRA, \oplus , in *Astronomy*. See EARTH.

TELMARA, in *Ancient Geography*, a town of Asia Minor, in Caria.

TELMEEN,

TELMEEN, in *Geography*, a town of Africa, in the country of Sahara, anciently called *Almæna*; 50 miles W. of Gabs.

TELMES, a town of Morocco; 15 miles from Safi.

TELMISSUS, in *Ancient Geography*, a name given to three towns in Asia Minor, one at the distance of 60 stadia from Halicarnassus, in Lycia; situated at the S.E. part of the gulf of Glaucus, $2\frac{1}{4}$ leagues N.E. of the promontory Telmessus, and nearly S.W. of the mouth of the river Glaucus. Its inhabitants were famous for their skill in augury: this town had a very fine theatre:—the second was in Caria, and the third in Pisidia.—Also, a mountain of Asia Minor, in Lycia.

TELO MARTIUS, a port of Gallia Narbonensis. See TOULON.

TELOBIS, a town of Spain, in the Tarragonese, belonging to the Jaccetani. Ptol.

TELOBO, in *Geography*, a small island in the East Indian sea, near the west coast of Gilolo. S. lat. $1^{\circ} 6'$. E. long. $127^{\circ} 15'$.

TELON, a name given by the chemists to fire.

TELONÆ, *τελωναι*, among the Athenians, farmers of the public revenues: for the severity with which they were handled, in case they failed, see Potter, *Archæol. Græc.* lib. i. c. 14. tom. i. p. 81.

TELONIUM. See THELONIUM.

TELONIUS, SALTO, in *Ancient Geography*, a river of Italy, in the country of the Sabines. It sprang towards the S. of Carseoli, and ran N. to discharge itself into the Velinus.

TELOPEA, in *Botany*, from *τηλωπος*, conspicuous at a distance, a name very suitable to this magnificent shrub, with its fine scarlet flowers.—Brown Tr. of Linn. Soc. v. 10. 197. Prodr. Nov. Holl. v. 1. 388. Ait. Hort. Kew. v. 1. 212.—Our *Embothrium speciosissimum*, with *E. truncatum* of Labill. Nov. Holl. v. 1. 32. t. 44, constitute this genus. See *EMBOTHRIUM*, from which we are unwilling to separate them, for the reasons given under *OREOCALLIS*. The extremely close natural affinity, and great resemblance, of these plants to each other, makes us mistrust even the technical character of the lateral stigma (omitted indeed in Hort. Kew.), supposing that organ to be really terminal in *Embothrium*, which on a careful inspection we find reason to doubt. The efficient part of the stigma in *E. coccineum* is certainly oblique. We wish to learn, rather than to dictate, but we cannot confide implicitly in the most able guide.

TELOS, PISCOPIA, in *Ancient Geography*, an island of the Archipelago, situated S.E. of the isle of Cos, and N.W. of that of Rhodes. Pliny says that it was celebrated for its perfumes.

TELPAH, in *Geography*, a town of Hindooistan, in Bahar; 40 miles S.S.W. of Patna.

TELPHUSSA, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia, upon an eminence, at some distance from the river Ladon, S.E. of Trophæa. A temple of Ceres was situated near this town, in which she was honoured under the name of Lusia.

TELUMNUM, a town of Aquitanic Gaul, on the route from Aquæ Tarbellicæ to Burdigala, between Cæquosa and Salamacum. Anton. Itin. This is the same with Tellonum.

TELWARAH, in *Geography*, a town of Hindooistan, in Agimere; 25 miles N. of Buddakano.

TEMA, a town of Africa, in the kingdom of Ningo, on the Gold Coast.

TEMACHIS, in *Natural History*, the name of a genus of fossils, of the class of the gypsums; the characters of which are these: it is of a softer substance than many of the other genera, and of a very bright and glittering hue. The name is derived from the Greek *τεμαχος*, *frustulum*, a small irregular fragment; the bodies of this genus being

composed of an assemblage of multitudes of irregular flaky fragments, as are all the gypsums; but no genus of them so visibly as these. Hill. See GYPSUM.

TEMALA, NEGRAIS, in *Ancient Geography*, a maritime town of India, on the western coast beyond the Ganges, S. of Berabonna, where the coast turns towards the E. at the W. mouth of the river Sabaracus.—Also, a river of India, the mouth of which was near Berabonna, and the promontory of Temala.

TEMAN, in *Commerce*, the name of a dry measure at Mocha, in Arabia, containing 40 mecmedas or kellas, and weighing in rice 168 lbs. avoirdupois.

TEMANIK, in *Geography*, a town of Persia, in the province of Kerman; 25 miles S. of Mastih.

TEMAPARA, in *Zoology*, the name of a peculiar species of lizard, called also *tejuguacu*.

It approaches much to the nature of the iguana, but is black, spotted with white.

TEMBA, in *Geography*, a province of the kingdom of Angola.

TEMBARE, a town on the west coast of the island of Celebes. S. lat. $1^{\circ} 21'$. E. long. $119^{\circ} 20'$.

TEMBASA, in *Ancient Geography*, a celebrated town of Greece, in the Peloponnesus. Pliny.

TEMBEN, in *Geography*, a town of Abyssinia; 100 miles E.S.E. of Siré.

TEMBLEQUE, a town of Spain, in New Castile; 13 miles E.S.E. of Toledo.

TEMBRIUM, or TYMBRIUM, in *Ancient Geography*, a town of Asia, in Phrygia.

TEMBROGIUS, a river of Asia, in Phrygia, which ran into the Sangarius.

TEMBRUS, a town of the island of Cyprus.

TEMBUL, in *Botany*, a name used by some authors for the plant called betel.

TEMDE, in *Geography*, a river of England, which runs into the Severn, 2 miles above Ludlow.

TEMDEGUE KIAMEN, a post of Chinese Tartary; 10 miles S.E. of Tciticar.

TEME, or TEAM, a river of England, which rises in the county of Radnor, and runs into the Severn, 2 miles below Worcester.

TEMEH, a town of Egypt, on the left bank of the Nile; 9 miles N. of Tahta.

TEMEH *Iffbag*, a town of Egypt; 12 miles N. of Fayoum.

TEMELET, a town of Morocco; 70 miles W.S.W. of Morocco.

TEMELO, in *Ichthyology*, a name used by some for the fish called in English the *grayling*, and in some places the *umber*.

TEMEN, in *Geography*, a town of Arabia, in the province of Nedsjed; 80 miles S.S.E. of Jamama.

TEMENDEFUST, or METAFUST, a town of Algiers; 10 miles E. of Algiers.

TEMENEH, a town of Asiatic Turkey, in Natolia; 52 miles W.N.W. of Sinob.

TEMENI, a town of the island of Candia; 6 miles S. of Candy.

TEMENI *Porta*, in *Ancient Geography*, a small town of Asia Minor, in Lydia.

TEMENIA, a town of Asia, in Phrygia, on the confines of Lycaonia.

TEMENIUM, a fortress of the Peloponnesus, on the confines of the Argolide. Here were two temples, one dedicated to Neptune, and another to Venus.

TEMERICUS AGER, a small country of Gallia Narbonensis, towards the source of the Rhine.

TEMES, in *Geography*, a river of Hungary, which rises in

in the south-east part of the mountains, and runs into the Danube, opposite Belgrade.

TEMESA, in *Ancient Geography*, a town of Italy, in Brutium, called Tempia or Temfa in the time of Strabo.

TEMESCAMANG, in *Geography*, the principal of those lakes in Lower Canada formed by the Utawas and its contributory streams, which lake has always been a trading port, and which may be said to continue, by a succession of rivers and lakes, upwards of 50 leagues from the Forks, passing near the waters of the lake Abbitiby, in N. lat. $48^{\circ} 30'$, which is received by the Moose river, that discharges itself into James bay. Mackenzie's Travels.

TEMESCHU, a town of New Mexico, in the province of Mayo; 160 miles E.N.E. of Santa Cruz.

TEMESVAR, or TEMESWAR, a town of Hungary. This is an important fortress, situated on the river Beg, which forms a morass round it, and is strongly fortified. It is the capital of a bannat, the residence of a governor, and the see of a Greek bishop. It was taken by prince Eugene in 1716; and by the peace of Passarowitz was, with the whole bannat, confirmed to the house of Austria; since which time it has been almost wholly rebuilt. It is large and populous; the streets broad and well paved. The fortress is a castle with walls nine feet thick, and requires a garrison of 14,000 men. It contains about 443 square German miles, with a population of about 450,000 inhabitants; 52 miles E.N.E. of Belgrade. N. lat. $45^{\circ} 49'$. E. long. 21° .

TEMIN, in *Commerce*, a money of account in Algiers, equivalent to 2 carubes, or 29 aspers. See COIN.

TEMISCHBERG, in *Geography*, a fortress of Russia, in the government of Caucasus; 60 miles W. of Stavropol.

TEMISSAH, or TEMMISSA, a large town of Africa, in the province of Fezzan, distant from Mourzouk, its capital, in an E.N.E. direction, about 120 miles. Here the caravan of pilgrims from Bornou and Nigritia, which takes its departure from Mourzouk about the end of October, or beginning of November, and travels by the way of Cairo to Mecca, arrives in the evening of the seventh day, and usually provides the stores of corn and dates, and dried meat, that are requisite for its dreary passage.

TEMISVAR. See BABA.

TEMITZ, a town of Bohemia, in the circle of Chrudim; 18 miles N.W. of Chrudim.

TEMLOWKA, a town of Algiers, anciently called "Sigus;" 24 miles S.E. of Constantina.

TEMMA, a town of Africa, on the Gold Coast. N. lat. $5^{\circ} 45'$. W. long. $0^{\circ} 55'$.

TEMMELISSUS, in *Ancient Geography*, a town of Asia, in Syria, on the route from Celecoma to Larissa, between Chalcida and Apamea. Anton. Itin.

TEMME, in *Geography*, a town of Sweden, in the government of Ulea; 20 miles S. of Ulea.

TEMNIKOV, a town of Russia, in the government of Tambov; 116 miles N.N.E. of Tambov. N. lat. $54^{\circ} 28'$. E. long. $43^{\circ} 14'$.

TEMNOS, in *Ancient Geography*, a town of Asia Minor, in Ionia, at the mouth and north of the river Hermus. It did not subsist in the time of Pliny.

TEMOEL, in *Geography*, a town on the west coast of the island of Celebes. S. lat. $0^{\circ} 5'$. E. long. $119^{\circ} 35'$.

TEMORIS, a town of New Mexico, in the province of Culiacan; 70 miles N.N.E. of Culiacan.

TEMOSOSHI, a town of New Mexico, in the province of Hiaqui; 130 miles E. of Riochico.

TEMPATLAHOAC, in *Ornithology*, the name of a broad-billed bird of the West Indies, described by Nierem-

berg; and by him esteemed a species of duck. It is a variety of the *anas clypeata*. See DUCK.

It is of the size of the common duck; is common on the lakes of Mexico, and is a good eatable bird. Ray.

TEMPE', in *Ancient Geography*, a celebrated valley of Thessaly, between the mountains Ossa and Olympus. Ælian, Pliny, and Strabo represent it as 40 stadia in length, along the middle of which lay the course of the river Peneus, which separated Thessaly from Macedonia. Tempé, according to Livy, was the name given to the wood or forest, which, though not dangerous, was difficult for an army to pass, because of two defiles five miles in length; and the river Peneus made a terrifying noise in passing through this deep valley. Tempé, it is said, is derived from the Greek *τυμπε*; in the plural, signifying wood. Tempé, at its entrance, has a large village, which has been long famous for the accomplishments of its inhabitants, and for the great trade they carry on with Vienna and the interior of Europe.

TEMPE, in *Commerce*. See STAMPE.

TEMPELBERG, in *Geography*, a town of Hinder Pomerania; 19 miles W. of New Stettin. N. lat. $53^{\circ} 29'$. E. long. $16^{\circ} 12'$.

TEMPER, in a *Physical Sense*. See MAN.

TEMPER of a Horse, the disposition of the animal, which should be carefully attended to while he is young, as well as in the purchase.

TEMPER, in a *Musical Sense*. See TEMPERAMENT, in Music.

TEMPER, in a *Mechanical Sense*. See TEMPERING.

TEMPERAMENT, TEMPERAMENTUM, *Temperature*, in *Physiology*. See MAN.

TEMPERAMENT, *Temperamento*, in Music, generally denotes a rectifying or amending of the false or imperfect concords, by transferring to them part of the beauty of the perfect ones.

The degrees of the octave, which may be called its *elements*, as being the smallest intervals into which it is resolvable, are two greater semitones, two less tones, and three greater tones.

Now the different situation of these elements, with respect to each other, occasions that intervals or concords of the same name, as thirds, fourths, &c. do not consist of the same degrees or elements, though there be always the same number of them: but one fourth, for instance, is agreeable and perfect, and another not.

To mend these imperfect concords, the musicians have bethought themselves to *temper*, *i. e.* give them part of the agreeableness of perfect ones. In order to this, they take a medium between the two, and this they call a *temperament*; which necessarily produces a new division of the octave, or, which amounts to the same, new elements.

For instance, whereas naturally its elements are the greater semitone, and the greater and less tone; they take a middle tone formed of the greater and the less: and the only elements now are the greater semitone, and this mean tone, which renders the five intervals that are tones equal, and those that are semitones less unequal to these.

One might also divide each of the five tones of the octave into semitones, which, joined to the two it naturally has, would make twelve: in which case, the whole octave would be divided into twelve equal parts, which would be mean semitones.

It is easy to form various other kinds of temperaments: all the difficulty is to find such as are free from two great inconveniences, *i. e.* which do not alter either all the concords too much, or, at least, some of them.

All such divisions of the octave are called *tempered* or *temperative system*.

The temperament does, indeed, according to the definition above given, and considered in one view, correct some false concords,

TEMPERAMENT.

conords, yet, in other respects, it spoils and falsifies both perfect and imperfect conords, and renders discords more harsh than they would otherwise be, if the intervals were justly taken. To explain this, we must consider that all the intervals are founded on the primary proportions arising from the numbers 2, 3, and 5, that is, if we do not exceed the compass of an octave, $\frac{2}{3}$, $\frac{3}{4}$, and $\frac{4}{5}$. See INTERVAL.

The nearer we come in practice to the true intervals, the more perfect the melody and harmony will be; and it is certain, that the human voice, and some instruments, as violins, &c. which have no stops nor frets, will execute music to a great degree of exactness; but the case is not the same with fixed or fretted instruments, as harpsichords, organs, lutes, viols, &c. Accuracy is here impossible, unless we would content ourselves with always playing in the same key, without any transition or transposition whatsoever. In this case, indeed, the harpsichord or organ might vie with the accuracy of the voice or violin. For instance: if we were to compose or play in the key of C, then we might make the several intervals of that key to be in the following true proportions, $1, \frac{9}{8}, \frac{10}{9}, \frac{11}{10}, \frac{6}{5}, \frac{16}{9}, \frac{5}{4}, \frac{15}{8}$, that is, in whole numbers, $\left\{ \begin{array}{cccccccc} C & D & E & F & G & A & B & C \\ 24 & 27 & 30 & 32 & 36 & 40 & 45 & 48 \end{array} \right\}$ and the instrument tuned in this manner, would perform any piece of music in C, justly composed, with great beauty and exactness; taking for granted, that every key, fundamental note, or sound, ought to have its true fifth and fourth, and that these ought also to have their true fifths and thirds.

Now this being premised, it will presently appear, that in making any transposition or transition from C, we shall find some false concord. Thus, for instance, if we proceed to G, and consider it as a key, or fundamental sound, we shall have the following series of numbers for the octave of G, viz. $\left\{ \begin{array}{cccccccc} G & A & B & C & D & E & F & g \\ 36 & 40 & 45 & 48 & 54 & 60 & 64 & 72 \end{array} \right\}$

But here the interval between 40 and 54 is false, being a comma too much, for the second of a key must make a true fifth with the fifth of the same key. In like manner, if we were to proceed from C to A, as a new key, we should find the following series for the octave of A, $\left\{ \begin{array}{cccccccc} A & B & C & D & E & F & G & a \\ 40 & 45 & 48 & 54 & 60 & 64 & 72 & 80 \end{array} \right\}$ where the interval between A 40 and its fourth D 54 is false, being too great by a comma. If any other transition were examined, we shall always find some note false; as in F, the sixth would be redundant by a comma; and in D, the fifth would be deficient by a comma. All which shews the impossibility of truth and exactness of music on fixed instruments. Yet as these instruments have their use and convenience in some respects, it was proper to endeavour to find out a method of making them tolerable. It has been observed under the article INTERVAL, that the tone major exceeds the tone minor by a comma. Their difference is necessary for the truth and perfection of music; but yet if these tones were rendered equal, the ear would not be offended. And this has suggested the means of tempering fixed instruments. If we were to make all tones equal to the tone major, as some imagine the ancients did, then we should find the ditonus, or third, exceeding a true third major by one comma, which would be intolerable. In like manner, if all tones were to be minor, we should have thirds major defective by a comma, which would also be intolerable, not to mention other false intervals that must necessarily arise from such a supposition.

Supposing then one tone increased, and the others diminished by half a comma, we should have our thirds major remain perfect. But still it would be necessary to examine what fifths this supposition would give. Now it is evident that a tone major added to an octave, makes just two fifths,

thus $\frac{2}{3} \times \frac{3}{2} = \frac{2}{2} = \frac{2}{2} \times \frac{2}{2}$. But the tone here added is a tone major, and the tone we have assumed is a temperate tone deficient from the tone major by half a comma; hence the sum of the two fifths, on this supposition, will fall short of the truth by half a comma, and consequently one fifth will be deficient a quarter of a comma. Which difference, although it be sensible, yet experience shews, that fifths so diminished are tolerable.

This temperament is what is called the common or vulgar temperament, and consists, as has been said, in diminishing the fifth by a quarter of a comma, in preserving the third major perfect, and dividing it into two equal tones. Which being supposed, it follows that the fourth must exceed the truth by a quarter of a comma; that the third minor will be deficient by the same quantity; that the sixth minor will be perfect, and the sixth major redundant by a quarter of a comma; and lastly, that the semitone major will exceed the truth by a quarter of a comma. If we introduce chromatic notes, or flats and sharps, the semitone minor will also exceed the truth by a quarter of a comma, and consequently the difference between the two semitones, or the diesis enharmonica, will be preserved.

If then we had a harpsichord or organ, with each note or half note divided, we should have the following notes or sounds, viz. C C*, D b, D, D**, E b, E, E**, G b, G, G**, A b, A, A**, B b, B, c, in the compass of an octave. Yet this system of notes, numerous as they seem, would not be sufficient for all transitions and transpositions. For though a piece of music transposed to any of the natural keys C, D, E, F, G, A, B, and to the flats, as E b and B b, and some others, would do well; yet, in transposing to sharps, as to C**, we should not find a true third major, unless we introduced E*. And even in flats, as A b and E b, we should not find a true third major in descending, or a sixth minor in ascending, unless we introduced F b and C b. And in like manner, transpositions to G* and E b would oblige us to introduce B* and C b. Nor would even this suffice, for if necessity required a transposition from the key of C to that of D**, we should not find a true third major without introducing F** and c. So that at last we shall come to a temperate system, where, in ascending, the notes C, D, F, G, A, would each have its sharp and double sharp, and the notes B and E each a single sharp. In descending, the notes E, D, B, A, G, would each have their flat and double flat, and the notes F and C each a single flat. And thus the octave would be divided into 31 intervals, whose designations are C D b b C* D b C** D E b b D* E b D**

$\begin{array}{cccccccccccccccccccccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 & 19 & 20 & 21 & 22 & 23 & 24 & 25 & 26 & 27 & 28 & 29 & 30 & 31 \\ C & F b & E* & F & G b b & F* & G b & F** & G & A b b & G* & A b b & G** & A & B b b & A* & B b & A** & B & C & B* & C. \end{array}$

Where the letters C, D, E, F, G, A, B, signify the common diatonic notes: those marked with a single * or b are the chromatic; and those marked with a double ** or b b are enharmonic notes; so called, because the interval between them and the next diatonic note is an enharmonic diesis; for which reason, the notes E*, F b, and B*, C b, are also enharmonic.

But even in this division of the octave, all the notes would not have a third major in ascending and descending: thus, for instance, D** has no third major; for this would be F***, which is not in the scale, nor can any number of additional notes suffice in all cases. But this inconvenience is easily remedied, and the system considerably improved, by making all the thirty-one intervals equal. We have already observed, that in

TEMPERAMENT.

the common temperament, the semitones major and minor exceed the truth by a quarter of a comma, and that the enharmonic diesis is preserved true. Hence it follows, that the hyperroche, or difference between the chromatic and enharmonic diesis; for example, the interval between F♭ and E♯, or D♭♭ and C♯, &c. will also exceed the truth by a quarter of a comma. Now the hyperroche, by our table under INTERVAL, is equal to 1.37695, to which adding a quarter of a comma = 0.25000, we have 1.62695, which differs from the enharmonic diesis 1.90917 only by 0.28222, or about $\frac{1}{7}$ of a comma. Neglecting this small difference, let us suppose all the thirty-one intervals of the octave equal, it will follow that transpositions to all the notes of the system, whether diatonic, chromatic, or enharmonic, will be equally good, and differ only in pitch or tone, as they ought, but not in accuracy, which must next be examined.

The division of the octave into thirty-one parts may be conveniently done by logarithms. Under the article INTERVAL, I find the logarithm of the octave = 55.79763 commas; consequently each diesis, or division of the octave, = 1.79992 comma; hence the fifth, being 18 diesis, will be 32.399 commas. Now the true fifths being 32.640, the fifth consequently in this temperament is deficient by 0.241 parts of a comma, which is less than a quarter of a comma by $\frac{1}{10}$ part; and therefore this fifth will, strictly speaking, be better than that of the vulgar temperament by $\frac{1}{10}$ of the comma; but this is insensible. Next, proceeding to examine the third, we shall find it equal to 10 diesis or divisions, that is, 17.999 commas; and the true third major being 17.963 commas, the difference is 0.036, that is, about $\frac{1}{27}$ of a comma. Now as the ear can bear a fifth, altered by a quarter of a comma, it will much more easily bear the alteration of $\frac{1}{27}$ of a comma in a third major. Again, in this temperament the third minor is indeed, strictly speaking, worse than in the vulgar, which differs from the truth but a quarter of a comma, whereas here it differs by about $\frac{1}{27}$ of a comma more; but then this difference is insensible.

Thus we have been led from the consideration of the vulgar temperament, to the invention of the temperament which divides the octave into 31 equal intervals, commonly called Huygens's temperament. This great mathematician was, indeed, the first who gave a distinct account of it, and shewed its use and accuracy. But here, as in many other inventions, we find the hint of the thing much older than the true knowledge of it. See Huygenii Opera omnia, vol. i. p. 748, 749, edit. 1. Lugd. Batav. 1724.

The division of the octave into 31 parts was invented in Italy about 300 years ago, by Don Nicola Vincentino. The title of his book is "L'Antica Musica Riddotta alla Moderna Prattica, &c." Roma, 1555. fol.; and an instrument, called *archicembalo*, was made upon this scheme, as Salinas informs us, who at the same time condemns it, as very disagreeable in practice. But this could be owing to nothing but its not being tuned according to the intention of the inventor. For if all the thirds major of this instrument were made perfect, and the fifths diminished by a quarter of a comma, it is evident that the instrument would be equally exact with any tuned according to the vulgar temperament, and would suffice for transpositions to any diatonic or chromatic notes, though not to all the enharmonic, as D♯♯, &c. because we should not find its third major. And if the instrument were tuned according to M. Huygens's scheme, of making all the divisions equal, it would then have all the 31 keys equally good, and very near the truth. See Salinas, lib. iii. The title of his work is "Francisci Salinæ Burgensis de Musica Libri Septem," Salnanticæ, 1577, fol. Merfennus's work is intitled "Harmonicorum, Libri XII. auctore F. M. Merfeno Minimo, Lutetiæ Parisiorum," 1648, fol. He published another book before this, the title

of which is "Harmonic Universelle, contenant la Théorie et la Pratique de la Musique," Paris, 1636, fol. 2 vols.

Hence it is plain, Salinas and Merfennus had not sufficiently examined this matter.

The use of this temperament of M. Huygens deserves to be introduced into the practice of music, as it will facilitate the execution of all the genera of music, whether diatonic, chromatic, or enharmonic; nor does the multiplicity of its parts render it impracticable, the author assuring us that he had a harpsichord made at Paris with such divisions, which was approved of and imitated by some able musicians. Merfennus also gives a scheme for this purpose; and Salinas says he saw and played upon such an instrument. See also Don Vincentino before cited, lib. v. p. 99, &c.

M. Huygens, to facilitate the tuning of instruments with such divisions, has given us a table of the parts of an octave, according to his system, together with their logarithms. The table is as follows:

The division of the octave into 31 equal parts.					The division of the octave according to the common temperament.

4.9999999993					

The second column of this table contains the numbers expressing the length of chords making 31 equal divisions, the longest, answering to C, being supposed to be divided into 100,000 parts.

In the third column are the syllables by which the notes are usually named in France; and the asteric * shews some enharmonic notes, of which that near *sol* is most necessary.

In the fourth column are the letters commonly used to denote the sound of the octave.

TEMPERAMENT.

The numbers of the second column were found by means of those in the first, which are their respective logarithms; and these were found by dividing 0.30102999566, the logarithm of 2, by 31. The quotient 97106450 is marked N, and being continually added to the logarithm of 50000, that is, to 4.6989700043, gives all the logarithms of the first column to the greatest 4.999999993, which being extremely near to 5.000000000, the logarithm of 100000, shews the operation to have been rightly performed.

The fifth column shews the lengths of the chords in the common temperament; and the sixth column contains their respective logarithms. Vide Huygenii Opera, vol. i. p. 752, 753.

The learned author of this temperament has not given the notes answering to all the divisions of the octave; but that may easily be supplied from what has been said above when we derived this temperament from the consideration of the common.

As Huygens has not given the names of all the intervals that occur in his temperate scale, we shall here insert them in the octave, from C to c, with their respective measures in the commas, and tenths of a comma

Intervals.	Names.	Measures.
From C to	Dbb 1. Diminished second, extreme flat second, or enharmonic diesis.	1.8
	C* 2. Semitone minor, or chromatic diesis.	3.6
	Db 3. Flat second, or semitone major.	5.4
	C** 4. Double semitone minor.	7.2
	D 5. Second, or tone.	9.0
	Ebb 6. Diminished third, or extreme flat third.	10.8
	D* 7. Superfluous second.	12.6
	Eb 8. Third minor, or flat third.	14.4
	D** 9. Extreme superfluous second.	16.2
	E 10. Third major, or sharp third.	18.0
	Fb 11. Diminished fourth.	19.8
	E* 12. Superfluous third.	21.6
	F 13. Fourth.	23.4
	Gbb 14. Extreme diminished fifth.	25.2
	F* 15. False fourth, or tritonus.	27.0
	Gb 16. False fifth, or semidiapente.	28.8
	F** 17. Extreme superfluous fourth.	30.6
	G 18. Fifth.	32.4
	Abb 19. Diminished sixth, or extreme flat sixth.	34.2
	G* 20. Superfluous fifth.	36.0
	Ab 21. Flat sixth, or sixth minor.	37.8
	G** 22. Extreme superfluous fifth.	39.6
	A 23. Sharp sixth, or sixth major.	41.4
	Bbb 24. Diminished seventh, or extreme flat seventh.	43.2
	A* 25. Superfluous sixth.	45.0
	Bb 26. Flat seventh, or seventh minor.	46.8
	A** 27. Extreme superfluous sixth.	48.6
	B 28. Sharp seventh, or seventh major.	50.4
	cb 29. Diminished octave.	52.2
	B* 30. Superfluous seventh.	54.0
	c 31. Octave.	55.8

The temperate diesis enharmonica of Huygens being 1.8 comma, nearly, which is easily remembered, the measure of any interval in the octave may be found by multiplying it by the number denoting the place of that interval. Thus the sixth minor, being the twenty-first interval, will be = $1.8 \times 21 = 37.8$. The octave, being the thirty-first, will be = $31 \times 1.8 = 55.8$, which does not differ from the truth by more than 0.00237, that is, not by $\frac{1}{420}$ of a comma, and therefore perfectly insensible. See INTERVAL.

All the intervals in the foregoing table, either have received names, or at least might receive them, from a perfect analogy to the names in use among practical musicians; but many of these intervals are as yet unheard of among practitioners. Perhaps, if all the genera of ancient music were restored, every interval here mentioned might be of use, either in melody or harmony, and thereby greatly add to the variety of composition.

We have already mentioned the advantages of M. Huygens's system; but its excellency will better appear by comparing it with the schemes of others. We may distinguish and name the different temperaments by the number of equal parts into which the octave is supposed to be divided. The temperaments that occur in books are temperaments of 12, 19, 31, 43, 50, 53, and 55 parts, of which in order.

The temperament of 12 parts is founded on the supposition that the semitones major and minor may be made equal. Hence the octave will be divided into 12 equal semitones, seven of which will make the 5th, four the 3d, and three the 3d minor.

The temperament of 19 parts goes upon the supposition that the semitone major is the double of the semitone minor, Hence the tone will be 3, and the third major 6. The diesis enharmonica will be 1, and consequently the octave, being three thirds major and a diesis, will be 19. The fifth contains 11 parts. The harpsichord, in this scheme, will have every feint cut in two, one for the sharp of the lower note, and the other for the flat of the higher. Between B and C, and between E and F, will be interposed keys, which must serve for the sharps of B and E, and the flats of C and F respectively.

The temperament of 31 parts is M. Huygens's, already described: here the semitones are as 3 to 2. The third major is 10, and the fifth 18.

The temperament of 43 is M. Sauveur's, and by him very fully described in the Memoirs of the Royal Academy of Sciences, A.D. 1701, 1702. He supposes the proportion of the semitones to be as 4 to 3. Hence his tone is 7, the third major 14, the fifth 25, and the octave 43. What musical foundation this learned gentleman went upon in the investigation of this temperament, is not known: but it seems liable to insuperable difficulties; for here the diesis enharmonica is but the half of the difference between it and the chromatic diesis: whereas, in truth, this difference, instead of being double of, is really less than the enharmonic diesis, as was long ago objected to him by Mr. Hensling, and appears from the table under INTERVAL. Miscel. Berolin. tom. i. p. 285, 286.

Besides, his enharmonic diesis falls greatly short of the truth; being but 1.27 of a comma, which is an error of 0.64, or nearly $\frac{1}{3}$ of a comma. Whereas, in M. Huygens's temperament, the error of the diesis is almost insensible, being but $\frac{1}{420}$ of a comma. Nor are the practical advantages of M. Sauveur's system any ways comparable to Huygens's. His fifth is indeed, strictly speaking, better; but so little, that the difference is not sensible, not being $\frac{1}{420}$ of a comma. On the other hand, his thirds are sensibly worse, the major being

TEMPERAMENT.

being $\frac{1}{3}$, and the minor $\frac{2}{3}$ of a comma false. Whereas Huygens's third major does not differ sensibly from the truth, and the minor has no sensible difference from the third minor deficient by $\frac{1}{3}$ of a comma of the common temperament, which ought to be deemed the limit of the diminution of concords. If we add to this, that the much greater number of parts in M. Sauveur's octave, makes it much more intricate than M. Huygens's, and that these parts would be false or useless, even supposing the enharmonic genus restored, no musician will long hesitate which he ought to prefer.

The temperament of 50 parts is proposed by Mr. Henfling in the Miscellan. Berolin. above cited: he takes the proportion of the semitone as 5 to 3: hence his tone is 8, the third major 16, the fifth 29, and the octave 50. The third major and fifth in this system will be worse than Huygens's, though the third minor be a little better. The third major is here less than the true, and the fifth deficient by more than $\frac{1}{3}$ of a comma, which is a fault, not to mention the inconveniency arising from dividing the octave into 50 parts; besides, 5 : 3, the proportion of the semitones here assumed, although expressed in greater numbers, is not so near the truth as M. Huygens's of 3 : 2. See RATIO.

The temperament of 53 parts is mentioned by Merfennus.

Here the tones will be unequal, 9 being the tone major, and 8 the minor. Hence the third major will be 17, and the fifth 31, which last does not differ from the truth by above $\frac{1}{3}$ part of a comma. The third minor is also more perfect than in M. Huygens's system. But the multiplicity of parts in the octave of this system renders it too intricate; and the distinction of tones major and minor upon fixed instruments is impracticable.

The last temperament we have to mention is that of 55 parts, which M. Sauveur calls the temperament of practical musicians. Its foundation lies in assuming the proportion of the semitones as 5 to 4; so that the tone will be 9, the third 18, and the fifth 32. The fifth in this system, as in that which makes the semitones equal, is nearer the truth than M. Huygens's, but this advantage is not $\frac{1}{3}$ of a comma; and on the other hand, the thirds, both major and minor, are here greatly mistuned, as will appear by the annexed table, exhibiting the thirds and fifths of these several temperaments, as also the thirds and fifths of the common temperament, and two mentioned by Salinas, marked 1st Salin. 2d Salin. The letter V. stands for the fifth; III. for the third major; and 3. for the third minor. The fifths are all deficient, but the thirds are sometimes less than the true; the first are marked +, the others -.

Temperaments formed by the division of the octave into equal parts, may be called geometrical temperaments. The common, and the two mentioned by Salinas, do not proceed upon this foundation; the intention of the first inventors not having been to make transpositions to every note of the system equally good; but only to make the most usual transitions in the course of a piece of music tolerable. Hence the parts of the octave, in their supposition, were not all equal.

The common temperament, as we have said, preserves the third major perfect. The first of Salinas preserves the third minor perfect. In the second of Salinas, the semitone minor is perfect. The foundation of his first temperament is making the temperate tone equal to the tone minor and $\frac{1}{3}$ of a comma, or the tone major less $\frac{2}{3}$ of a comma. Hence his fifth and third major will be deficient by $\frac{1}{3}$ of a comma; and the third minor consequently will be true. The ground of his second scheme is, to add $\frac{2}{3}$ of a comma to the tone minor, or take $\frac{1}{3}$ from the tone major for his temperate tone. Hence the fifth will be deficient by $\frac{1}{3}$ of a comma, and the thirds major and minor each deficient by $\frac{1}{3}$ of a comma. Consequently, the semitone, being their difference, will be preserved.

As to Mr. Salmon's scale in the Philosophical Transactions, there is nothing true in it, but the diatonic scale of C. His scale for A is false, the fourth being erroneous by a comma; most of his semitones are likewise false. In

short, it can neither be considered as a true scale, nor as a temperament.

Before we close this article, it may be proper to add a few words about the method of invention of the foregoing geometrical temperaments. M. Huygens having had the hint of a division of the octave into 31 parts, had nothing farther to do but to examine it by logarithms. But supposing no such hint had been given, he might have investigated it directly, by the method laid down by himself, and also by Dr. Wallis and Mr. Cotes, for approximating to the value of given ratios in smaller numbers. We have given Mr. Cotes's method under RATIO. The application of that method to the present purpose is thus: the ratio of the octave to the third major is 55.79763 to 17.96282, and the approximating ratios will be,

1. Greater than the true 28 : 9, 87 : 28, &c.
2. Less than the true 3 : 1, 31 : 10, 59 : 19, 205 : 66, &c.

The ratios greater than the true must all be rejected; because they give the third major less than true, and consequently the tone (its half) deficient by above $\frac{1}{3}$ of a comma; which gives the fifth deficient above $\frac{1}{3}$ of a comma: but this ought not to be. The first of the ratios less than true is 3 : 1, or 12 : 4, which is the temperament of 12 parts before described, and too inaccurate. The next is 31 : 10, or M. Huygens's. The rest divide the octave into too many parts.

The same may be also found thus: the ratio of the octave to

to the common temperate fifth, deficient by $\frac{1}{4}$ of a comma, is 56.79763 to 32.38952. The approximating ratios to which are,

1. Greater than the true 2 : 1, 7 : 4, 19 : 11, 50 : 29, &c.
2. Less than the true 1 : 1, 3 : 2, 5 : 3, 12 : 7, 31 : 18, 205 : 119. Where we have the temperaments of 12, 19, 31, and 50 parts, before examined.

And here all ratios greater than the true ought to be rejected, because they give the fifth less than true, that is, in this case, deficient by more than $\frac{1}{4}$ of a comma.

If we investigate the approximating ratios to the ratio of the semitones major and minor, or 5.19529 to 3.28612, we shall have the ratios 1 : 1, 2 : 1, 2 : 2, 5 : 3, which respectively give the temperaments of 12, 19, 31, and 50 parts, before described.

Again, investigating the approximating ratios of the fifth to the third major, we shall find 7 : 4, 9 : 5, 11 : 6, 29 : 16, which will also give the temperaments 12, 19, 31, 50, as before.

Lastly, the approximated ratios of the octave to the true fifth are 12 : 7 and 53 : 31 greater than the true; the others being of no use, since the fifth must necessarily be diminished. Here we find the temperament of 53 parts. As to the temperaments of 43 and 55, being destitute of any musical foundation, it is no wonder they do not appear by this method of investigation.

M. Huygens, in his Cosmotheoros, says that the tone or pitch of the voice cannot be preserved, unless the consonants be tempered, so as to deviate a little from the highest perfection. For the proof of this assertion, he brings a melody consisting of the following sounds, C, F, D, G, C; where, if the intervals were to be sung perfect, by taking the interval from C to F a true fourth ascending, from F to D a third minor descending, from D to G a true fourth ascending, and lastly, from G to C a true fifth descending, we should fall a comma below the C from whence we began. Therefore, if we were to repeat this series of notes nine times, we should at last fall near a tone major below our first found.

M. Huygens's solution of this difficulty is, that we remember the note from whence we set out, and return to it by a secret temperament, thereby singing the intervals a little imperfect; which, he says, will be found necessary in almost all songs or melodies.

A like difficulty is mentioned in the Memoirs of the Royal Academy of Sciences; and is there urged for the necessity of a temperament, even for singing in the same key. And M. Huygens's solution of the difficulty is there approved of. Ann. 1707, p. 264.

But the solution of these learned gentlemen is, as yet, far from being decisive. No experiment has yet been brought to shew that the human voice sings tempered notes; not even when accompanied by tempered instruments. It seems to us, on the contrary, that an exercised voice, guided by a good ear, sings true, even though accompanied by a mistuned instrument, as harpsichords most frequently are, especially in transposed keys. And were these instruments always as well tuned as art could make them, yet their tones would be equal; and it seems evident to the ear, that the human voice singing naturally two tones in succession, as C, D, E, never makes them equal: and cannot, without great difficulty, and by means of a variation of harmony, be brought to make them equal.

Another solution, therefore, of M. Huygens's difficulty, must be sought for. The truth seems to be, that the second of the key must be the true tone major above the key and therefore the third between the second and fourth of the

key must be sung deficient by a comma. Thus in the key of C, from C to D will be a tone major = $\frac{9}{8}$, and from D to F will be a deficient third = $\frac{4}{3}$. See INTERVAL.

M. Huygens's melody, therefore, will stand as follows:

$$\left\{ \begin{array}{cccccc} C & F & D & G & C \\ \frac{4}{3} \times \frac{9}{8} \times \frac{4}{3} \times \frac{9}{8} = 1 \end{array} \right\}$$

And the voice would sing the interval F, D, just as if the note E had been interposed; in which case the notes would be

$$\left\{ \begin{array}{cccccc} C & F & E & D & G & C \\ \frac{4}{3} \times \frac{9}{8} \times \frac{9}{8} \times \frac{4}{3} \times \frac{9}{8} = 1 \end{array} \right\}$$

These notes all come within the diatonic scale of C; and the voice naturally falls upon the note from whence it set out. The same answer will hold in the example mentioned in the Memoirs of the Academy of Sciences; where the intervals bB, G, E, C occur. And here the interval from bB to G should be taken = $\frac{4}{3} = \frac{9}{8} \times \frac{9}{8}$, as in the former example; and for the same reason, the key being F.

There seems, therefore, no repugnancy between the practice and theory of music, while the melody is confined to one key; but it must be owned, that in transitions from key to key, especially where several parts are to make harmony with each other, there still remain difficulties, not mentioned by M. Huygens, or any other writer we know of, which might deserve a farther examination.

We must not omit mentioning, that the learned Dr. Smith, in his Harmonics, has not only carried the theory of temperaments far beyond all the authors that preceded him; but has shewn how to tune an instrument according to any proposed temperament, by the ear only, which is certainly a most ingenious discovery.

This learned author prefers what he calls the temperament of equal harmony, which differs insensibly from the division of the octave into fifty parts, to all others; and insists, that it labours under the fewest defects, and is of all others the most agreeable in practice. In the system of equal harmony, the temperaments of the fifth, third major and third minor, are respectively $\frac{1}{15}$ and $\frac{1}{16}$ and $\frac{1}{18}$ of a comma less than the truth.

It would be impossible here to do justice to the learned author's reasonings on this subject; we shall only add, that he establishes, contrary to the common opinion, that the less simple consonances, generally speaking, will not bear so great temperaments as the simpler consonances.

Dr. Smith mentions a temperament communicated to him by the ingenious Mr. Harrison, which consists in making the proportion between the octave and third major equal to that of the circumference of a circle to its diameter. In this temperament the third major is diminished by $\frac{2}{3}$ of a comma, but the third minor is very near the truth, and extremely beautiful.

A late author seems to think the division of the octave into thirty-one parts, not to be of modern invention, but necessarily implied in the doctrine of the ancients. At first sight, it would seem as if the ancients made but twenty-four dieses or divisions in the octave, viz. ten to each fourth, and four to the tone; which (the octave being equal to two fourths and a tone) gives twenty-four dieses to the octave. But the author just quoted contends, that this division is to be understood only in one tension, that is, either ascending or descending; but that, accurately speaking, if we consider all the dieses, or divisions of the fourth, both ascending and descending, we shall find thirteen; five to each tone, and three to the semitone major; and consequently thirty-one divisions in the octave. These, indeed, are not all naturally equal; but if we make them so, we

shall have a temperament known by the moderns under the name of Huygens's temperament. Dr. Pepusch, in Phil. Trans. N° 481. p. 273. See the article **DIESTS**.

Such was the history and theory of temperament about half a century ago. But as our keyed and wind instruments have extended their compass and powers, and all the ancient laws of relative modulation are disregarded by modern composers, most practical musicians incline to equal harmony, in which all the keys participate of the imperfection of the scale when the octave is confined to twelve semitones, of which every one occasionally serves for two or three different purposes. As the note A natural, for instance, is sometimes B double flat, and sometimes G double sharp, E natural is obliged to officiate for D double sharp, and sometimes for F flat.

There are, however, theorists who calculate, but never listen, and who think temperament an abomination, a deadly sin against Pythagoras and his *triple progression*. Now as it is generally agreed that the ancients had no simultaneous harmony, or music in parts, and allowed of no consonances but the unison, octave, 4th, and 5th, they did wisely to make them as perfect as possible; but since the invention of counterpoint, and new instruments of six tones by keys, frets, and additional ventages, which furnish but twelve semitones, whereas thirty-one different sounds are wanting to supply two distinct sounds for synonymous notes, such as A* and B♭, C* D♭, D* E♭, &c. temperament, though it a little diminishes the perfection of certain notes, the whole instrument is bettered by it, and rendered equally fit for all keys. Every concord, except the unison and octave, has a latitude, and allows of *bearings* without offending the ear. A perfect 5th makes an intolerable major 3d below it. And as the 3d, though called an imperfect concord, is the most grateful and pleasing of all the concords when perfect; contrapuntists do wisely to allow tuners to rob 4ths and 5ths of a little of that perfection which they can spare without injury, for the good of the whole. If the learned harmonist, the abbé Roullier, is living, this relaxation of Pythagorean discipline, and want of due respect for the *triple progression*, will, we fear, disturb and render him somewhat intemperate in censuring our *absurdity*.

We have always regarded music as an object for the ear, and wish to make it as pleasing to that sense as possible; and have been so long accustomed to tempered scales, as to receive more pain than pleasure from music performed on an instrument tuned by perfect 5ths throughout, that is, by the *triple progression*. We shall, however, prescribe no exclusive method of tempering the scale; as almost every man who tunes his own instrument has a system of his own: we shall only observe, that the greatest musicians in the course of their lives have often changed their method. In our cathedrals and parish-churches in general, where the natural keys are made as perfect as possible, at the expence of A♭, D♭, F*, and C*, keys that have never been admitted within the pale of the church, organists that hear little other music, are extremely offended by equal participation of the scales, when the pure harmony of their favourite keys is deformed by temperament: and those accustomed to the levelling system of equal harmony, on the contrary, hold the *wolf* in as much abhorrence, as they would the destructive wolf in the Gevauden. At present, our tuners mitigate the extremes of equal and unequal temperament, by favouring the natural keys, and making the extraneous or transposed keys somewhat less perfect; but devoting the *wolf* to total destruction.

It is imagined by many, that the character of keys, par-

ticularly the minor, depends on the imperfection of the scales, occasioned by unequal temperament: as F minor is plaintive, E♭ solemn, and E* brilliant. But though the difference between the pitch of E♭ and E*, D* and E♭, is but half a note, whatever may be the general pitch of the instrument, whether half a note too high, or half a note too low, these keys still retain their character, it should seem not from the tuning or elevation of the general system, but from something for which we are unable to account. See **MUSIC**, and **SOUND**.

TEMPERATE ZONE. See **ZONE**.

TEMPERATURE, in general, denotes the degree of free caloric which a body appears to possess when compared with other bodies; or, in other words, the state of a body in relation to its capability of producing in other bodies the effects arising from the presence of free caloric. Sir Humphrey Davy defines temperature to be "the power bodies possess of communicating or receiving heat, or the energy of repulsion." But this definition appears to us to be a little ambiguous, for temperature is not a term indicative of a positive faculty in bodies, as this definition may be understood to mean; but, as before observed, is merely a relative term, expressive of the degree in which bodies, in conformity to the grand law of the equal distribution of free caloric, can affect, or be affected by other bodies of a lower or higher temperature, that is, possessing more or less free caloric than themselves.

There are two means of measuring the temperature of bodies, namely, by our sensations, or by the different degrees of expansion produced in bodies on being subjected to different degrees of free caloric. The first of these, from various obvious causes, is so imperfect and limited, that no dependence can be placed upon it as a measure of temperature. The second is much more regular and extensive, and is, therefore, always at present employed. "When two bodies produce the same increase or diminution of volume in a third body, to which they are equally applied, they are said to be of the same temperature; and any body is said to be at a higher or lower temperature, as it produces a greater or less expansion in another body with which it is in contact." Instruments founded upon the principle of the expansion of bodies by heat, and destined to measure degrees of temperature, are called *thermometers*, or, when the temperature is very high, *pyrometers*; which see. Under the same heads also the important question is discussed, how far the expansion of bodies by heat is to be considered as an indication of their real temperature. See also **CALORIC**.

TEMPERATURE of the Atmosphere. See **ATMOSPHERE**.

TEMPERATURE of Climate. See **CLIMATE**.

TEMPERATURE of the Earth, is that degree of sensible heat which exists on the surface, or in the interior of the solid part of the globe. The temperature of the atmosphere is frequently described as the same with the temperature of the earth, from which it is essentially distinct. The sensible heat of the atmosphere varies with the latitude, the season, and the elevation of the place in which the observation is made. The superficial temperature of the earth varies also with the latitude and the season, and in a still greater degree if the land be dry; but the internal temperature of the earth appears to be permanent in each place throughout the whole year. At a certain depth under the surface, the thermometer always indicates the same degree of heat; and the difference between the permanent internal temperature in different latitudes, is much less than that which exists at the surface. The depth at which the thermometer remains stationary about latitude 52°, is 80 feet: nearer to the equator,

TEMPERATURE.

equator, or the poles, a greater depth would be necessary to obtain the permanent temperature. At still greater depths, probably, the temperature under each degree of latitude is the same all over the globe, except in the vicinity of volcanic fires.

M. Volney, in his travels through North America, speaking of the temperature of the earth, endeavours to oppose the opinion of its permanent internal temperature. Setting out from lake Superior, he says, and proceeding west to the Stoney mountains, and travelling north as far as latitude 72° , the country now well known to the Canadian traveller, displays a climate that for severity of cold can be compared only to Siberia. From latitude 46° , the earth is frozen during the whole year. At several trading posts between latitude 50° and 56° , it was found impossible to have wells. Mr. Shaw had attempted to dig one at the post of St. Augustin, about forty miles from the mountains; but though it was in the month of July, the ground was frozen at the depth of three feet from the surface, and as it grew harder he was obliged to give up the attempt. He relates also an account of Mr. Robson, an English engineer, who attempted to sink a well at Prince of Wales's fort, latitude 59° , in the month of September. He first found thirty-six inches of earth thawed by the preceding warm weather, then a stratum of eight inches frozen as hard as a stone; under this a stratum of sandy friable earth, frosty and very dry, in which his borer could find no water. The celebrated traveller Ledyard, says Volney, affirms, that at Yakutsk, not so high as latitude 62° , wells of water cannot be obtained, because it is found by experiment that water freezes at the depth of sixty feet. From these circumstances, M. Volney would infer that the internal part of the earth is in a constant state of congelation. Some of the above observations, we believe, were inaccurately made; and it has been too hastily determined, that the earth is frozen during the whole year in North America, even in latitude 46° ; for this is not the case 11° further north. We have been favoured with the following statement from an intelligent medical gentleman, who was some years resident in Hudson's Bay. "On digging a well at York fort, Hudson's Bay, latitude $57^{\circ} 7'$, in the beginning of October, the following circumstances were remarked. About thirty inches from the surface, a bed of frozen earth, about twelve inches thick, was met with: below was a bed of loose sandy clay, about half a yard thick, which was succeeded by a bed of the same clay, rendered perfectly hard and solid by frost. Sinking lower, similar beds of frozen and loose earth were found, alternating with each other; the frozen beds, however, constantly decreasing in thickness, though not regularly, and at a certain depth they seemed to disappear entirely. These frozen strata are considered by the inhabitants as indications of the severity of the preceding winters, each stratum being supposed, with much probability, to be formed in different years, and to be travelling downward until they are thawed by the internal temperature of the earth. The process by which they sink down may be explained, on the supposition that the upper surface is diminishing by heat during summer, and the under surface increasing by the congelation of moisture in contact with it. Another circumstance, which took place in the same latitude, may serve to elucidate the observation of Ledyard, that the water was constantly frozen at sixty feet under the surface at Yakutsk." A well had been sunk which yielded a plentiful supply of water during the first summer; but the water, being exposed to the air, froze during the next winter, and remained frozen ever after, being too far below the surface to be thawed. Hence it appears that water

exists unfrozen at a moderate depth under the surface in the coldest climates, when it has no communication with the external air. The effect of the summer heat in the same latitude extends about seventeen inches under the surface, where the ground has been shaded; but where it has been exposed to the sun, the surface is thawed to the depth of three feet. From the small depth to which the solar heat penetrates, we may infer that the water below is kept in a fluid state by the internal heat of the globe. It has been generally supposed, that the permanent temperature of each latitude is the same nearly as the mean annual temperature of the atmosphere, and that this is indicated by the temperature of springs or deep wells; but the temperature of springs will vary with that of the strata near the surface through which they run. (See *TEMPERATURE of Springs*.) It is to be regretted that more numerous observations have not been made on the temperature of deep mines. From observations recently made in Cornwall, it appears that the temperature increases with the depth, at least in some of the mines, and in the lowest it was not less than 70° . This may, perhaps, be owing to the chemical changes which are taking place; for it appears, from the evidence of the overflows of the mines, in reply to certain queries proposed by the Royal Geological Society of Cornwall, that the water is found constantly warmer in the vicinity of veins of copper-ore, than it is in the vicinity of tin-ore: the former veins are in general worked to a greater depth than the latter. It remains to be ascertained whether this increase of temperature be owing to chemical causes, or is invariable at the same distance from the surface. The decomposition of pyrites in copper veins would seem to point out a cause for the increased temperature in their vicinity; it is evident, however, that it is not derived from the solar rays. It seems reasonable to believe, from what we at present know of the internal temperature of the earth, that there exists a permanent source of heat within the globe, though we are unacquainted with the causes by which it is generated. We are equally ignorant of the causes by which light is generated on the surface of the sun: one operation is not more surprising or inexplicable than the other; nor is the difficulty removed, by supposing the sun to be surrounded with a luminous atmosphere. Some philosophers have maintained the opinion, that the earth has been constantly growing colder since the period when it was first inhabited, and that the organic remains of elephants and other animals, (supposed to be similar to those of tropical climates,) which are found in Siberia, offer a demonstrative proof, that the arctic regions once enjoyed the temperature of the torrid zone. It has since been ascertained, by the elaborate researches of M. Cuvier, that these animals were not of the same species as the African or Asiatic elephant. A most convincing proof of this was afforded by the entire body of one of these elephants, which was discovered imbedded in ice near the mouth of a river in the north of Siberia, by a Tungusian fisherman, in the year 1799. It first presented a shapeless mass projecting from an ice-bank. Two years afterwards he could distinctly see that it was the body of an enormous animal; the entire flank and one of its tusks had become disengaged from the ice. In 1803, the ice beginning to melt earlier than usual, the whole body was disengaged, and fell from the ice-bank on the sandy shore. In 1806, Mr. Adams went to examine this animal, which still remained on the sand, but its body was much mutilated. The skin was extremely thick and heavy, and as much of it remained as required the exertions of ten men to carry away. More than thirty pounds of the hair and bristles of the animal were collected. Some of this

TEMPERATURE.

this hair was presented to the Museum of Natural History in Paris. It consists of three distinct kinds. The one is stiff black bristles, a foot or more in length; another kind is a coarse flexible hair, of a reddish-brown colour; the third kind is a coarse wool, which grew among the roots of the long hair. These afford undeniable proof, that this animal belonged to a race of elephants inhabiting a cold region, and was not fitted to dwell in the torrid zone. This animal was a male, and had a long mane on its neck. The bones were all perfect. As the only proof offered for the refrigeration of the earth was the former existence of tropical animals in northern latitudes, and as this can no longer be maintained, we have reason to believe that the general temperature of the globe is stationary, though the climate of particular countries may vary at different periods, from cultivation, the destruction of large forests, or other local causes.

Though the annual changes in the temperature of the climate affect the surface only to a small comparative depth, yet the continued effect of the annual mean temperature, considered as a permanent cause, may be sufficient to keep the internal temperature of the earth stationary, in each latitude, at a still greater depth. Hence we find that the internal temperature of the earth, and the mean temperature of the atmosphere, are nearly, but not exactly, the same; for in all northern countries, the mean temperature of the earth is higher than that of the air, and the difference, according to the observations of Dr. Wahlenberg, fellow of the Royal Society of Stockholm, appears to increase as we advance northward, or as the cold of the winter becomes more severe. This would also seem to give additional confirmation to the opinion, that there is a permanent source of heat within the globe itself. The following table shews the rate at which the temperature varies according to the latitude.

	Latitude.	Temp. of the Earth.	Mean Temp. of the Atmosphere.
Berlin - - -	52.5°	49.28°	46.4°
Carlstrom - - -	56.25	47.3	42.03
Upsala - - -	60.	43.70	33.38
Umen - - -	64.	37.22	
Degeforts - - -	64.25	36.68	

The observations were made on springs which threw up a large quantity of water at a permanent degree of temperature in all seasons. It is to be regretted that we have not a series of observations made with equal care in southern latitudes. M. Volney states, in his "Travels in America," that the mean temperature of wells forty-five feet deep was as under:

	Fahr.
Charlestown - - -	63°
Virginia - - -	57
Philadelphia - - -	53
Massachusetts - - -	49
Vermont - - -	44

This depth is too small, to give the true mean temperature of the earth; and the observations can only be regarded as approximations to the truth. On the same authority it is stated, that the temperature of the earth, to a considerable depth under the torrid zone, is 14° Reaumur, or 63° Fahrenheit.

In the southern parts of England, the mean temperature, taken from permanent springs, is about 48°; at Edinburgh, 45°; in the north of Ireland, 48°; and at Paris, 51°.

For the temperature of the atmosphere, see ATMOSPHERE, where the mean temperature in different latitudes is given. Mr. Humboldt has lately published a botanical account of the new genera and species of plants discovered in the tropical regions of America, with many interesting observations on the temperature, as affecting the growth of plants. The plants of the torrid zone extend farther through the southern temperate zone than through the northern, owing to the greater influence of the ocean in the southern hemisphere, in moderating the rigour of winter; the ocean bearing a much greater proportion to the surface on the south, than on the north side of the equator. In estimating the climate suited for the growth of particular plants, the mean temperature will not afford a correct standard; for though the mean temperature of the year, in the middle latitudes of North America, be the same as it is in Europe, 7° further north, the temperature of different seasons in these same latitudes by no means agrees. The winters are colder, and the summers hotter, in North America than in Europe. In Philadelphia the summer is as hot as at Rome or Montpellier, while the winter corresponds with that at Vienna. At Quebec the summer is warmer than at Paris, but the winter colder than at St. Petersburg. In the north of China there is a still greater difference between the heat and cold, than in North America.

In North America, as far as latitude 48°, the summers are four centigrade degrees, or about 7° Fahrenheit, hotter than in the corresponding latitude in Europe. Between the tropics, the mean annual temperature is the same as on the old continent, which may be seen in the following table, expressed in degrees of the centigrade thermometer.

	Old Continent.	New Continent.
Senegambia	26.5°	Cumana 27.7°
Madras	26.9	Antilles 27.5
Batavia	25.2	Vera Cruz 25.6
Mantilla	25.6	Havannah 25.6

Twenty-five degrees correspond with seventy-seven degrees of Fahrenheit.

Though the plants of the torrid zone extend farther through the southern temperate zone than through the northern, as we have before stated; yet to a certain distance from the line, the temperature appears to be less on the south than on the north side. Rio Janeiro and Havannah are nearly at the same distance from the equator; but the mean temperature of the summer and winter months in each is as under:

	Rio Janeiro.	Havannah.
June	20.0°	December 22.1°
July	21.2	January 21.2
January	26.2	July 28.5
February	27.0	August 28.8

On the coast of Peru, the temperature is diminished by the perpetual cloudiness of the sky, and by a strong sea current setting in from Cape Horn. From the tropic to 34° of south latitude, the mean temperature of the southern hemisphere scarcely differs from that of the northern. Between latitude 34° and 57°, there is a greater difference between the temperatures of summer than of winter: the winters in the southern hemisphere are not colder, but the summers are considerably more so than in the northern hemisphere. In south latitude 48°, the summer temperature is the same as the winter temperature of Toulon, Cadiz, and Rome.

The higher we ascend above the level of the sea, and the farther we advance from the equator, the greater is the difference

TEMPERATURE.

ference between the temperature of different seasons of the year. The following table exhibits the temperature between the hottest and coldest months, in different latitudes.

	Lat.	Cent. Therm.
Cumana - - -	10.27°	2.4°
Vera Cruz - - -	19.11	2.6
Havannah - - -	23. 8	7.4
Natches - - -	31.28	17.4
Philadelphia - - -	39.56	24.6
Quebec - - -	46.47	33
Nain - - -	57.00	35

In the temperate zone, as we advance northwards, the coldness of the winter increases at a much greater rate than the heat of the summer diminishes. Thus at Enonleki, in latitude 68° 30', the temperature of July is as hot as that of Edinburgh. Between the tropics, the temperature at no season of the year equals that of the sea-shore; but in the temperate zone, the upper currents of air are sometimes warmer than the lower, during the winter months; and the thermometer, on the summits of hills, is occasionally three or four degrees higher than in the plains. Hence in the temperate zone, we find the same plants frequently on low and elevated situations; but this is never the case between the tropics. In the temperate zone on the old continent, when

the mean heat of the month is as under, the following plants blossom:

Fahr.
42°, the <i>Amygdalis perfica</i> ,
47, the <i>Prunus domestica</i> ,
52, the <i>Betula alba</i> .

The reason why plants vegetate with greater rapidity in Lapland and Norway than farther south, is owing to the increment of temperature being much greater, and to the temperature of the earth in winter being several degrees above that of the air.

From observations made in different latitudes, it appears that 1000 fathoms of altitude occasion a diminution of temperature equal to 23° of Fahrenheit; 50 fathoms being nearly equal to half a degree. Mountains 1000 fathoms in height, at 46° of latitude, have the mean temperature of Lapland; and mountains of the same height between the tropics enjoy the temperature of Sicily.

The following table by Humboldt exhibits the most remarkable circumstances respecting the temperature in the three zones. The temperature is taken according to the centigrade thermometer. The fathom 6 French feet, or 6.39453 English feet.

	Torrid Zone.		Temperate Zone.			Frigid Zone.
	Andes, Quito, Lat. 0°.	Mountains of Mexico, Lat. 20°.	Caucasus, Lat. 42½°.	Pyrenées, Lat. 42¾°.	Alps, Lat. 45½° to 46°.	Lapland, Lat. 67° to 70°.

In the seventh volume of the Transactions of the Royal Society of Edinburgh, Dr. John Murray has published a paper on the diffusion of heat on the surface of the earth; in which he attempts to prove, from the nature of caloric, that the temperature of the earth is constantly increasing from the solar rays, and that this temperature is becoming more equal in different parts of the earth. The atmosphere, he contends, conveys no heat into unlimited space; our planet, in relation to the discharge of caloric from it, is bounded as it were by a wall of iron-conducting matter. He admits,

however, that a small portion of heat may be lost by radiation: thus, at the hotter parts of the earth's surface, there may be some emission of caloric by radiation; but this, he says, cannot be equal to the quantity communicated by the solar rays: for of the heat derived from the latter source, a portion is absorbed by the earth, and conveyed to the interior, as is apparent from the decreasing temperature, as we recede from the surface to a certain depth; and another portion is carried off by the ascending current of heated air, and conveyed to colder regions, where it is absorbed. Thus,

TEMPERATURE.

even from those parts of the surface of the earth where the circumstances are most favourable to radiation, the quantity radiated cannot be equal to the quantity received from the solar rays. Over the whole earth the diffusion must be still greater; and instead of the conclusion, that the planet discharges its excess of heat by radiation, there is every reason to draw the opposite conclusion, that part of the heat which it receives from the sun is retained. He further infers, that the temperature of the globe must rise, from the mode in which heat is communicated to it by the sun; and at the same time, as it advances, must become more equal over the whole surface. And this rise has its limits. There cannot be either unlimited increase of heat, or unlimited refrigeration; but the final result will be a state of permanence and uniformity, the continuance of which is secured by the very circumstance, that if it is deviated from, this deviation must correct itself by an increase of radiation from the hotter parts, or from an increased absorption of caloric by the colder parts of the globe. According to this theory, in process of time, the equatorial and polar parts of the globe will arrive at the same degree of temperature, which will remain stationary, as there will be no circulation of heated air or water to the poles. To this reasoning we conceive it may be objected, that it assumes, without sufficient grounds, that caloric cannot pass from the earth into unlimited space, and that the solar heat does not become latent by chemical union with terrestrial substances. It assumes also, that caloric is a distinct specific substance; an opinion which is denied by some of the most eminent philosophers. Nor have we, perhaps, any evidence to prove that the temperature of the earth has changed since the earliest records of history, if we except the local changes which result from drainage and cultivation. It is well known that the climate of Europe is materially changed since the periods of ancient history, when the Danube was annually frozen, and would admit the passage of armies over the ice. The climate of the United States of America has also undergone a material change during the last century. Both these local changes have been produced by the same cause, the destruction of extensive woods, and the progress of agriculture; but, independently of local causes, we have no data to infer that the temperature of the globe is increasing or diminishing.

TEMPERATURE of the Sea. The temperature of the sea near the surface is affected by the changes of temperature of the atmosphere, and by the currents which traverse it. The currents which flow from the equatorial to the polar regions, serve to equalize the heat of different latitudes. This is remarkably the case with the current called the Gulf stream, which passes by the shores of Mexico, Louisiana, and Florida, and round the point of the peninsula, under the shelter and protection of the Bahama islands, which break the efforts of the ocean and the current of the trade wind. This stream, on entering the ocean, preserves its water by the velocity of its current, and may be further distinguished by its colour and temperature. The temperature is from eleven to twenty-two degrees higher than that of the ocean. From the Floridas to Newfoundland the current continues increasing in breadth, and diminishing in velocity. Some experiments made by Mr. Jonathan Williams, give the difference of temperature between the Atlantic ocean and the Gulf stream as under, December, 1789.

On approaching the coast of England, - - -	48°
Capt. Billings, in 1791, found the temperature of } the sea on the coast of America, - - - }	61
In the water of the Gulf stream, - - -	77

In winter, Mr. Williams found the variation between the Gulf stream and the ocean 23°; the difference, as might be expected, being less in summer than in winter. These inquiries have ascertained another fact, from whence navigators may derive some advantage; for by examining the temperature of the sea in different places, it has been found that the water is colder in proportion to its shallowness; and hence may be derived an indication of the approach to land, or to a shoal. Out of the reach of currents, a difference always exists between the temperature of the surface and the lower parts of the sea. In northern latitudes, the surface is sometimes warmer and sometimes colder than the lower parts; but near the equator, the temperature of the surface may be expected to be invariably warmer than at great depths. In all probability, the temperature of the sea is permanent in each degree of latitude; at a certain depth. Capt. Ellis let down a sea-gage in N. lat. 25° 13'. W. long. 25° 12'. He found the sea colder and colder in proportion to the depth, till the gage had descended 3900 feet, when the mercury in the thermometer came up at 53°; but the water did not grow colder, though he let down the gage 1400 feet lower. At the surface of the sea, the thermometer stood at 64°.

From the experiments of Capt. Douglas, near the coasts of Lapland and Norway, of which an account is given in the 60th volume of the Philosophical Transactions, the following differences were observed between the temperature of the sea at the surface, and at certain depths.

Temperature at the Surface.		Depth in Fathoms.	Temperature.
May 12, } lat. 70° 40', }	}	36° Fahr.	78 to 87 } 40

TEMPERATURE.

From the above observations it appears, that though the sea at a moderate depth was cooler than at the surface during the summer months in northern latitudes, yet at still greater depths the temperature increased, and at the depth of 260 fathoms was 52° in July, when the surface was only 47°. Now this depth being below the immediate effects of the solar rays, the temperature could only be derived from that of the globe itself, which appears to be sufficient to preserve the sea many degrees above the freezing point at the depth of 300 fathoms. Indeed, the temperature of the sea near the tropics, in lat. 25° 13', at the depth of 650 fathoms, appears to be the same as the temperature of the sea in lat. 68° 43', at little more than one-third of that depth, as may be seen by comparing the observations of Capt. Ellis with that of Capt. Douglas. We have hence also strong grounds for believing, that at a certain depth, the temperature of the sea is permanent, and is the same in every degree of latitude from the equator to the pole, though the depth may vary at which this permanent temperature would be found.

The mean annual temperature of the standard situation in every latitude, as deduced by Mr. Kirwan from the Atlantic and Pacific oceans, is given under the article *Temperature of the ATMOSPHERE*. But some exceptions to this standard, not there noticed, deserve to be mentioned here.

That part of the Pacific ocean which lies between N. lat. 52° and 66°, is only about 45 miles broad at its northern extremity, and 1300 miles at its southern. It is, therefore, reasonable to conclude with Mr. Kirwan, that its temperature will be considerably influenced by the surrounding high land, as well as by the many bleak islands scattered through it. Mr. K. supposes, that from these circumstances the temperature is fully four or five degrees below the standard. Small seas surrounded by land are usually rendered, from this circumstance, at least in temperate and cold climates, warmer in summer and colder in winter than the standard ocean: the gulf of Bothnia, for instance, is stated to be generally frozen in winter, but in summer to be sometimes heated to 70°. The German ocean is above three degrees colder in winter, and five degrees warmer in summer, than the Atlantic. The Mediterranean sea is, for the greater part of its extent, warmer both in summer and winter than the Atlantic, which therefore flows into it. The Black sea is colder than the Mediterranean, and flows into it.

These observations apply chiefly to the surface of the ocean: from experiments that have been made it appears, that at considerable depths the temperature is much lower than at the surface, and that the deeper we go, the lower it becomes; so that some suppose that, at very great depths, the water always exists in a state of ice. See Kirwan's "Estimate of the Temperature of different Climates;" also his "Essay on the Variation of the Atmosphere."

TEMPERATURE of Springs. Those common springs which throw up a considerable quantity of water during the whole year, have generally a permanent temperature, or nearly so; and this is supposed to represent the mean temperature of the earth in each latitude; but there are other springs which have a much higher permanent temperature, and some which throw up their waters at a boiling heat. The following is the permanent temperature of some of the more celebrated warm springs in Europe.

Bareges, - - - -	120

The Geysers or boiling fountains in Iceland, in the Azores, and in various parts of the world, have a constant temperature of 212°. The source of heat, in some of the latter springs, is evidently subterranean fire, as all those islands are of volcanic origin, and are the seats of active volcanoes at the present day. It is observed of other warm springs, that they generally rise in the vicinity of volcanic or basaltic rocks. This is the case with the warm springs of Matlock and Buxton. Rocks of basaltic amygdaloid extend through the high peak of Derbyshire, where these springs are situated. Rocks of basaltic amygdaloid, having a still more near resemblance to volcanic lava, extend from Worford bridge, in Gloucestershire, in a direction southward, and, in all probability, are continued under the surface to Bath and Bristol. According to Humboldt, hot springs rise from granite and rocks denominated primary, in various parts of South America; and, from the permanent high temperature of warm springs, we may infer that the source of heat is situated deep beneath the surface, and far below those causes which can change the temperature. It has been contended by some persons, that the high temperature of warm springs arises from the decomposition of pyritous strata; but if this were the case, the waters would be strongly impregnated with sulphate of iron and other mineral matters, which is not the fact; the temperature would also decrease as the pyritic matter became exhausted, of which we have an analogous illustration in the saline springs of Cheltenham and Gloucester. These springs rise in a deep stratum of blue clay, called *lias*, (see *STRATA of England*;) which abounds in pyrites, and in animal remains; and it is found by experience, that the saline impregnation is greatest when the wells are first opened, and that the strength of the waters gradually declines; on which account, the proprietors are under the necessity of sinking fresh wells to obtain water of the requisite saline strength. This might be expected; for as the water percolates through fissures in the clay, the saline matter in its vicinity is gradually washed away. But if the whole bed were in a state approaching to ignition, from the decomposition of pyrites, the saline impregnation would be constantly supplied to the springs; for we cannot suppose any quantity of pyritous matter to exist equal to heat a whole stratum by decomposition, without, at the same time, generating such an abundance of saline matter as must saturate the waters which percolate through it. We are hence led to infer that the source of heat in warm springs is subterranean fire, and as these springs have not been observed to diminish in temperature for a period of nearly two thousand years, we may further infer the great depth at which this source of heat is situated, an inference which is warranted by the connection which volcanoes in distant parts of the world appear to have with each other. (See *VOLCANO*.) It may be asked, if the source of heat in warm springs be subterranean fire, why are they not all of the same degree of temperature? To this it may be replied, that, in some instances, the warm springs may be intermixed with cold springs near the surface; and in other instances, after rising to a certain height, they may run in an horizontal direction for a considerable distance among the upper strata, and thus be gradually cooled. The cause which can raise up water from vast depths, must be sought for in the expansive power of steam, and elastic vapours generated by heat, which we know by experience to be fully adequate to the effect.

TEMPERATURE for Plants, in Gardening, the state of heat in which it is necessary to keep particular sorts of them, in order to their striking or taking root, their healthy growth, and their succeeding in the best and most proper manner. The state or degrees of heat, or the temperature, in all such cases, must be regulated and directed by the nature of the plants, their culture, and the situations in which they are grown. For those in hot-houses and stoves, the temperature, in those of the dry stove kind, should mostly be from about fifty to seventy degrees, according to the natures, habits, and manners of growth of the plants; and in those of the moist stove kind, from about sixty to ninety degrees, as the nature of the beds and plants may be. Plants in conservatories are kept at various temperatures between those of the first kind of the above stoves and that of the common open air. And in greenhouses, nearly similar temperatures are constantly to be preserved, in order to the raising, and to the growth of such plants, in the most suitable and best manner.

It is always of great utility and importance to keep the temperatures as steady as possible, whatever its state may be, in the growth of all these sorts of tender plants.

The temperatures, or states of heat for particular plants, are mostly given under their proper heads, in describing their culture.

TEMPERATURE of Milk for Cheese, in Rural Economy, the degree of heat which is the most proper in milk for the purpose of making cheese. From some experiments which have been lately made upon the subject, this temperature would seem to be about the middle point between that of summer and blood heat; or, perhaps, somewhere about ninety degrees of Fahrenheit's scale may give the average degree of warmth which is most proper and necessary in the business.

TEMPERING, in the Mechanic Arts, the preparing of steel and iron, so as to render them more compact, hard, and firm; or even more soft and pliant; according to their respective occasions.

These metals are tempered by plunging them, while red-hot, into some liquor prepared for the occasion: sometimes pure water is used for that purpose: our locksmiths, &c. scarcely use any other.

When an instrument has been properly hardened, it is necessary to give it a certain degree of softness, in order to adapt it for the purpose to which it is to be applied. With this view, it should be heated again to a certain point, usually determined by its colour, and then instantly plunged into cold water. This is called "letting it down to the proper temper." It has been a question of difficult solution, how the water acts in hardening iron and steel. It is well known, says Mr. Parkes, in his "Chemical Essays," (vol. iv.), that the hotter any piece of iron is made, and the more quickly it is cooled, the harder it will become in its texture; and he suggests that this may be owing to the loss of its latent heat. In confirmation of this conjecture he alleges, that iron and steel are generally allowed to owe their malleability to their latent heat.

A composition of divers juices, liquors, &c. has sometimes been used; which is various according to the opinion and experience of the workman: as vinegar, mouse-ear water, nettle or Spanish radish-water, the water oozing from broken glasses, suet, oil, foot, distilled wine, sal ammoniac, urine, &c. But these methods are now generally abandoned. Mr. Stodart, a very ingenious and scientific cutler in London, says, (as Mr. Nicholson informs us, Journal, vol. iv. 4to.) that one of his workmen makes up his charcoal-fire with shavings of leather, finding that this is effectual in pre-

venting the tools from cracking in the process of hardening; and he says, that he has found no advantage from the use of salt in the water.

To harden and temper English, Flemish, and Swedish steel, you must give them a pretty high heat; then suddenly quench them in water to make them hard; but Spanish and Venetian steel will need only a blood-red heat before they be quenched.

In consequence of this operation, all the qualities of steel are changed; so that from being very ductile and soft, it becomes so hard and stiff, that it is no longer capable of being cut by the file, but is itself capable of cutting or piercing very hard bodies, and that it does not yield to the hammer, but may be sooner broken in pieces than extended. It becomes also sonorous, brittle, very elastic, and capable of acquiring the most beautiful polish. This hardness and ductility of steel may be diversified by varying the temper. The hotter the steel is when tempered, and the colder the water into which it is plunged, the greater hardness it acquires, but at the same time it becomes so much more brittle. The coldness of the water may be increased by dissolving salts in it: observing that water is always colder while the salts continue dissolving; and that the steel will cool sooner by being stirred about or placed in a stream, so as to come in contact with water not already made warm. On the contrary, the less hot the steel is when tempered, and the hotter the water is in which it is tempered, the less hard it becomes, and also the greater ductility it retains: and the proper degree of heat is always relative to the use for which the tools made of the steel are intended.

If the steel be too hard or brittle for an edged tool, &c. let it down by rubbing a piece of grindstone or whetstone hard upon the work, to take off the black scurf: then brighten, or heat it in the fire: and as it grows hotter, you will see the colour change by degrees, in the manner and by the gradations stated under the article CUTLERY.

Saw-makers temper their tools by rubbing them over with suet or other grease, and then heating them gradually till the temperature of each tool is sufficiently raised to set fire to the grease of itself and occasion it to blaze. They are thought to acquire in this mode of treatment a temper equal to that which would be obtained by heating them in the usual way, till they became of a deep blue. This operation, which is practised at Sheffield, is called "blazing." For the method of tempering files, in which the great desideratum is to blend tenacity with hardness, see FILE.

In the year 1789, Mr. David Hartley took out a patent for a method of tempering steel by the aid of a pyrometer or thermometer applied near to the surface of the article, and at the same time recommended the use of heated oil, in which (he says) many dozens of razors or other tools might be tempered at once with the utmost facility, and the various degrees of heat necessary for different purposes might speedily be determined by experiment. (See Nicholson's Journal, vol. i. 4to.) An improvement of this principle has been since suggested by Mr. Parkes (Chem. Ess. vol. iv.) by providing a bath of oil or of some kind of fusible metal for the tempering of every species of edged tool, which contrivance would, in his opinion, give to this operation a greater degree of certainty, than has ever been experienced by those who have conducted such manufactories. See TILTING.

Steel is usually fold tempered, because in many manufactures, the custom is to temper it as soon as it is made, probably that the purchasers of it may be better able to judge of its quality. When this steel is to be used, it must be untempered by heating it more or less, and letting it cool

cool slowly; that it may be extended, filed, and receive the necessary form: after which every workman tempers it again in his own way.

M. Berthoud, in his treatise on marine clocks, recommends hardening the steel-balance wheel, by daubing it over with foot (of wood) moistened with urine, putting it into a small box of thin iron-plate, and covering it over with the same composition. This box with its contents is to be heated to a blood-red, and then the wheel taken out suddenly and quenched.

Mr. Harrison and M. Berthoud seem to agree upon the whole, that the balance-spring of time-pieces should be hardened and tempered after it has been coiled up in its proper form; and not tempered first and coiled up afterwards, as is the practice in making the main-spring. Some curious workmen, in order to equally temper small steel instruments, employ melted lead as an intermedium. A plate of iron floats upon the melted lead, and receives from it, in all its parts, an equal heat: the pieces of steel laid upon this plate, acquire all at once the same degree of heat, and are at once quenched in water; the blue or other colours, which they successively assume, affording sure marks of the proper points of heat at which they are to be quenched, according to the different degrees of hardness required in them. Lewis's Com. Phil. Techn. p. 32.

For the method of tempering steel bars for artificial magnets, practised by Mr. Canton, see *Artificial MAGNET*.

The ancients appear to some to have had a better method of tempering than any of the moderns are acquainted with; witness their works in porphyry; a stone so hard, that scarcely any of our tools make any impression upon it.

TEMPERING of Land, in Agriculture, a term signifying the preparing it for a crop, especially of wheat. It is a term in much use in Norfolk. It implies all the various operations that may be undertaken in this intention.

TEMPEST, TEMPESTAS, a storm or violent commotion of the air, with or without rain, hail, snow, &c.

TEMPEST, in Mythology, a deity among the Romans, concerning whom we merely know, that Marcellus, as an acknowledgment for having escaped a storm, with which he was overtaken at sea, between the islands of Corsica and Sardinia, built a temple to her without the Porta Capena.

TEMPESTA, ANTONIO, in Biography, was an ingenious designer and painter, born at Florence in 1555, and was initiated in the art by Santi di Titi; afterwards he studied under another artist, whose name was Stradanus. Tempesta was gifted with a brilliant and powerful imagination, not, however, of the most correct or exalted kind. His favourite subjects were battles, sieges, cavalcades, huntings, processions, &c.; all of which he arranged and designed in a novel and rich style, and executed with uncommon spirit and energy. He was employed by Gregory XIII. in the Vatican, which he adorned with grotesque inventions, and some few historical productions. He was also employed by the marchese Justiniani in decorating his palace; and in several of the churches of Rome, Tempesta's paintings may be found.

He not only exercised his genius and time with the pencil, but devoted much of both to the etching needle; having left behind him nearly 1800 plates of different kinds, and of very considerable merit. He died in 1630, aged 75.

TEMPLE, in Geography, a town of the island of Sardinia; 25 miles E. of Castello Arragonese.—Also, a town of Mexico, in the province of Guadalajara; 500 miles N.W. of Mexico.

TEMPLARS, TEMPLERS, or Knights of the Temple, a

religious military order, first established at Jerusalem, in favour of pilgrims travelling to the Holy Land.

The original of this order, the first military one in the world, is this: in 1118, some pious and noble persons devoted themselves to the service of God, in the presence of the patriarch of Jerusalem; promising to live in perpetual chastity, obedience, and poverty, after the manner of canons.

The two principal persons were Hugo de Paganis, and Geoffry of St. Omers. Baldwin II. then king of Jerusalem, gave them an apartment in his palace, near the temple at Jerusalem, not far from the sepulchre of our Saviour; whence their denomination *Templars*.

Soon afterwards, the canons of the temple gave them a piece of ground near the said temple, on which to build regular houses; and the king, the lords, the patriarch, and the prelates, each gave them somewhat out of their revenue for food and cloaths.

Their first undertaking, and what they had first in view at their institution, was, to guard the highway against robbers, &c. chiefly for the safety of pilgrims and croises.

The principal articles of their rule were: that they should hear the holy office throughout every day; or that, when their military duties should prevent this, they should supply it by a certain number of pater noster: that they should abstain from flesh four days in the week, and on Fridays from eggs and milk-meats: that each knight might have three horses, and one squire: and that they should neither hunt nor fowl.

In the year 1228, this order acquired stability, by being confirmed in the council of Troyes, and subjected to a rule of discipline drawn up by St. Bernard.

In every nation they had a particular governor, called *master of the temple*, or of the *militia of the temple*. Their grand-master had his residence at Paris.

The order of Templars flourished for some time, and acquired by the valour of its knights immense riches, and an eminent degree of military renown: but as their prosperity increased, their vices were multiplied, and their arrogance, luxury, and cruelty, rose at last to such a monstrous height, that their privileges were revoked, and their order suppressed with the most terrible circumstances of infamy and severity. Their accusers were two of their own body, and their chief prosecutor Philip the Fair, of France, who addressed his complaints to Clement V. The pope, though at first unwilling to proceed against them, was under the necessity of complying with the king's desire, so that, in the year 1307, upon an appointed day, and for some time afterwards, all the knights, who were dispersed throughout Europe, were seized and imprisoned. Such of them as refused to confess the enormities of which they were accused, were put to death; and those who, by tortures and promises, were induced to acknowledge the truth of what was laid to their charge, obtained their liberty. In 1312, the whole order was suppressed by the council of Vienne. A part of the rich revenues they possessed was bestowed upon other orders, especially on the knights of St. John, now of Malta, and the rest confiscated to the respective treasuries of the sovereign princes in whose dominions their possessions lay.—The knights Templars, in order to justify the severity with which they were treated, were charged with apostacy to the Saracens, and holding correspondence with them; with insulting the majesty of God; turning into derision the Gospel of Christ; and trampling upon the obligation of all laws, human and divine. Candidates, it is said, upon admission to this order, were commanded to spit, in token of contempt, upon an image of Christ, and after admission, to worship either a

cat, or a wooden head crowned with gold. It is farther affirmed, that, among them, the odious and unnatural act of sodomy was a matter of obligation; and they are charged with other crimes too horrible to be mentioned, or even imagined. However, though there be reason to believe that in this order, as well as others of the same period, there were shocking examples of impiety and profligacy; yet that the whole order was thus enormously corrupt, is so far from being proved, that the contrary may be concluded even from the acts and records, yet extant, of the tribunals before which they were tried and examined. If to this we add, that many of the accusations advanced against them flatly contradict each other, and that many members of this unfortunatè order solemnly avowed their innocence, while languishing under the severest tortures, and even with their dying breath; it would seem probable, that king Philip set on foot this bloody tragedy, with a view to gratify his avarice, and glut his resentment against the Templars, and especially against their grand-master, who had highly offended him. The principal cause of this invincible hatred against them was, that in his quarrel with Boniface VIII. the knights espoused the cause of the pope, and furnished him with money to carry on the war. Mosheim's Eccl. Hist. vol. iii. ed. 8vo. Bower's Hist. of the Popes, vol. vi. p. 393.

TEMPLE, TEMPLUM, a public building erected in honour of some deity, either true or false; and in which the people meet to pay religious worship to the same.

The word is formed from the Latin *templum*, which some derive from the Greek *τεμενος*, signifying the same thing; and others from *τεμνω*, *abscindo*, *I cut off*, *I separate*, because a temple is a place separated from common uses; others, with more probability, derive it from the old Latin word *templare*, *to contemplate*. It is certain the ancient augurs gave the name *templa* to those parts of the heavens which were marked out for the observation of the flight of birds. Their formula was this: *Templa tesqua sunt*.

Temples were originally all open, and hence received their name. See Phil. Trans. N° 471. sect. 5. where we have an account of the ancient temple in Ireland of the same sort as our famous Stonehenge.

The word *templum*, in its primary sense among the old Romans, signified nothing more than a place set apart, and consecrated by the augurs, whether enclosed or open; in the city, or in the fields.

Clemens Alexandrinus and Eusebius refer the origin of temples to the sepulchres built for the dead. This notion has been lately illustrated and confirmed by a variety of testimonies by Mr. Farmer, in his Treatise on the Worship of Human Spirits, p. 373, &c. Herodotus, Lucian, and Strabo, will have the Egyptians to have been the first who built temples to the gods; and from them the custom was propagated to the Assyrians, comprehending under this appellation Phœnicia, Syria, and other countries. From Egypt and Phœnicia it passed to Greece with the colonies, and from Greece to Rome. The first erected in Greece is ascribed to Deucalion by Apollonius (Argonaut. lib. iii.) and the first in Italy to Janus.

In antiquity we meet with many people who would not build any temples to their gods, for fear of confining them to too narrow bounds. They performed their sacrifices in all places indifferently, from a persuasion, that the whole world is the temple of God, and that he required no other. This was the doctrine of the magi, followed by the Persians, the Scythians, the Numidians, and many other nations mentioned by Herodotus, lib. i. Strabo, lib. xv. and Cicero, in his second oration against Verres.

The Persians, who worshipped the sun, believed it would wrong his power, to enclose *him* in the walls of a temple, who had the whole world for his habitation; and hence, when Xerxes ravaged Greece, the magi exhorted him to destroy all the temples he met with.

The Sicyonians would build no temples to their goddesses Coronis; nor the Athenians, for the like reason, erect any statue to Clemency, who, they said, was to live in the hearts of men, not within stone walls.

The Bithynians had no temples but the mountains to worship on; nor had the ancient Germans any other but the woods.

Even some philosophers have blamed the use and building of temples, particularly Diogenes, Zeno, and his followers the Stoics. But it may be said, that if God hath no need of temples, men have need of places to meet in for the public offices of religion: accordingly, temples may be traced back even unto the remotest antiquity. See Hospinian, de Origine Templorum.

The Romans had several kinds of temples; of which those built by the kings, &c. consecrated by the augurs, and in which the exercise of religion was regularly performed, were called, by way of eminence, *templa*, temples. Those that were not consecrated were called *ædes*. The little temples, that were covered or roofed, they called *ædicula*; those open, *facella*. Some other edifices, consecrated to particular mysteries of religion, they called *fana* and *delubra*.

All these kinds of temples, Vitruvius tells us, had other particular denominations, according to the form and manner of their construction; as will be hereafter specified. Indeed, the Romans out-did all nations with regard to temples: they not only built temples to their gods, to their virtues, to their diseases, &c. but also to their emperors, and that in their life-time; instances of which we meet with in medals, inscriptions, and other monuments. Horace compliments Augustus hereupon, and sets him above Hercules, and all the heroes of fable; in that those were only admitted into temples after their death, whereas Augustus had his temples and altars while living.

“Præfenti tibi maturos largimur honores;
Jurandasque tuum per nomen ponimus aras.”

Epist. ad Aug.

Suetonius, on this occasion, gives an instance of the modesty of that emperor, who would allow of no temples being erected to him in the city; and even in the provinces, where he knew it was usual to raise temples to the very proconsuls, refused any but those erected in the name of Rome as well as his own. Vide Suet. in Octav. cap. 52.

Whenever a temple was to be erected, the aruspices were consulted as to the site of it, and the time when the construction of it was to commence. The spot assigned to it was carefully purified, and it was encircled with fillets and garlands. The vestals, accompanied with young boys and girls, washed the ground with water, and the priest expiated it by a solemn sacrifice. Then he touched the foundation-stone, and bound it with a fillet; and the people, animated with extraordinary zeal, threw it in thither with some pieces of money, or metal which had not passed through the furnace. When the edifice was finished, it was consecrated with a variety of ceremonies, in which the priest, or, in his absence, some of his college, presided. Some of these temples were not to be built within the precincts of cities, but without the walls, as those of Mars, Vulcan, and Venus, for reasons particularly assigned by Vitruvius. The temples were held in great veneration; and, in some cases, they were a sanctuary for criminals and debtors. Within they were
very

very much adorned; particularly with costly statues of their gods and great men, and a great variety of votive offerings.

The most celebrated of the ancient temples among the Pagans were the following: viz. the temple of Belus (see *BELUS* and *BABYLON*); the temple of Vulcan at Memphis, the magnificence and extent of which are highly extolled by Herodotus; the temple of Jupiter at Thebes or Diospolis; that of Amon at Hermunthis; that of Proteus at Memphis; that of Minerva at Sais; the temple of Diana at Ephesus (see *DIANA*); the temple of Apollo in the city of Miletus, which, as well as that of Diana, was of the Ionic order; the temple of Eleusis, built in honour of Ceres and Proserpine, capable of containing 30,000 persons; the temple of Jupiter Olympius at Athens, of the Corinthian order; and the temple of Apollo at Delphi, so famous for its oracles, and for the rich presents with which it was enriched (see *DELPHI*); the temple of Jupiter, which contained his admirable statue. The architect of the temple was Libo, a native of the country: its height from the area to the roof was 68 feet, its breadth 95, and its length 230. The throne and statue of the god, for we cannot enumerate other splendid ornaments, were the master-piece of Phidias; and antiquity produced nothing so magnificent nor so finished. The statue, of an immense height, was of gold and ivory, so artificially blended, that it could not be beheld but with astonishment. The god wore upon his head a crown, which resembled the olive-leaf to perfection: in his right hand he held a victory, likewise of gold and ivory; and in his left a sceptre of exquisite taste, resplendent with all sorts of metals, and supporting an eagle. The shoes and mantle of the god were of gold; and upon the mantle were all sorts of animals and flowers engraved. The throne was all sparkling with gold and precious stones. The ivory and ebony, the animals there represented, and several other ornaments, by their assemblage, formed a delightful variety. At the four corners of the throne were as many Victories, that seemed to be joining hands for a dance, besides two others that were at Jupiter's feet. The feet of the throne, on the fore-side, were adorned with sphinxes, who were plucking the tender infants from the bosom of the Theban mothers; and underneath were to be seen Apollo and Diana, wounding Niobe's children to death with their arrows. Four cross bars that were at the feet of the throne, and went from one end to the other, were adorned with a great number of figures extremely beautiful: upon one were represented seven conquerors at the Olympic games; upon another appeared Hercules, ready to engage with the Amazons, and the number of combatants on either side was twenty-nine. Besides the feet of the throne, there were likewise pillars to support it. In fine, a great balustrade, painted and adorned with figures, railed in the whole work. Pausanias, an able painter of that time, had represented there, with inimitable art, Atlas bearing the heavens upon his shoulders, and Hercules in an attitude stooping to ease him of the load: Theseus and Pirithous, the combat of Hercules with the lion of Nemea, Ajax offering violence to Cassandra, Hippodamia with her mother, Prometheus in chains, and a thousand other subjects of fabulous history. In the most elevated place of the throne, above the head of the god, were the Graces and Hours, of each three in number. The pedestal which supported this pile, was equally adorned with the rest. There Phidias had engraved upon gold, on the one side, the Sun guiding his chariot; on the other, Jupiter and Juno, the Graces, Mercury, and Vesta. There Venus appeared rising out of the bosom of the sea, and Cupid receiving her; while Pitho, or the goddess of persuasion, was presenting her with

a crown. There also appeared Apollo and Diana, Minerva and Hercules. At the bottom of the pedestal, you might have seen Amphitrite and Neptune, and Diana or the moon, who appeared mounted on horseback. In fine, a woollen veil, of a purple dye, and magnificently embroidered, the present of king Antiochus, hung from top to bottom. The throne and statue reached from the pavement, which was of the finest marble, to the roof.

Italy abounded with temples as much as Greece; several of which were remarkable for their singularity or magnificence. Rome was full of temples: some of the most remarkable for their origin, materials, structure, or use, were the following: viz. the temple of Apollo, built by Augustus, in honour of his favourite deity Apollo, after his victory at Actium, upon mount Palatine. Its structure was very magnificent; it was built of the finest marble of Claros, and embellished, both within and without, with the richest ornaments. Its gates were of ivory, enriched with basso-relievos, representing the Gauls, when they were thrown headlong from the top of the Capitol by T. Manlius. In the frontispiece was a chariot of the sun, of massy gold, crowned with rays so resplendent that they dazzled the eyes of beholders. Within the temple was a marble statue of Apollo, made by Scopas, and also a colossal one of brass, 50 feet high; together with a candlestick in the form of a tree, whose branches were covered with clusters of lamps resembling fruit. Upon these branches the poets used to hang their poems, which they offered up to Apollo, as Horace informs us, ep. 3. l. 1. To this temple, dedicated to the "god of arts," was very properly annexed a noble library.—The temple of Bacchus, situated without the walls of Rome, is now the church of St. Constantia, supported on the inside by twenty-four noble pillars of granite. Its ancient mosaic ceiling, and the old window by which light was let in from the roof, still remain. Behind the present altar stands an antique urn of porphyry, of large dimensions; and on each side of the altar, a finely wrought antique candlestick of marble.—Here was the temple of the goddess Bona, who was Dryas, the wife of Faunus, distinguished by her exemplary chastity. The Roman ladies sacrificed to her in the night, in a little chapel, into which the men were not allowed to enter, nor were they permitted to be present at her sacrifices. It was for the violation of this rule, that Cicero prosecuted the debauched Clodius. (See his article.)—The temple of Diana was seated on mount Aventine. It was built in the reign of Servius Tullius, at the joint expense of the Romans and Latins, for the purpose of their meeting annually to offer a sacrifice, in commemoration of the league made between the two nations.—The first temple of Faith is said to have been erected by Numa, who taught the Romans to worship this goddess, and thus to be reminded, that the most sacred oath they could take was to swear by their *faith* or *veracity*. His intention was to render their promises, without writings or witnesses, as firm and certain as contracts made and sworn to with the greatest formalities; and in this he succeeded to his wish. Polybius bears this honourable testimony to the Romans, that they inviolably kept their *faith*, that is, their word, without having occasion for witnesses or securities; whereas nothing could bind the Greeks to their promises.—The temple of Honour was built by Mutius, by order of Marius, and might be reckoned among the noblest buildings in ancient Rome, if the materials, which were stone, had corresponded to the greatness of the design. It was remarkable for this circumstance, that the entrance of it was dedicated to Virtue, and the rest to Honour; and that it had no posticum, or back-door, as other temples had; thus intimating, that we must not only pass through virtue to attain

to honour, but that honour is also obliged to repass through virtue, that is, to persevere in it, and acquire more of it.—The temple of Janus. The Romans built, at different times, three temples to Janus; for an account of which, see JANUS.—The temple of Jupiter the Preserver was one of the sixty temples that stood upon the Capitoline hill. Jupiter Custos was represented in it, holding his thunder with one hand, and a dart with the other, and the figure of the emperor was under his thunder, to shew that he was under Jupiter's protection; or else engraved, lying upon a globe, and holding an image of victory, with the eagle at his feet, and these words, "Jovi Conservatori Augustorum nostrorum."—The temple of Jupiter Optimus Maximus, or Jupiter Capitolinus, was most commonly called the *Capitol*; which see.—The temple of Liberty was built upon mount Aventine, on the spot where Cicero's house once stood, enriched with several brass pillars, and many fine statues.—The temple of Mars stood on the declivity of the Capitoline hill. In this temple were kept the eagles and other military ensigns of the Romans, and also the chariot in which Cæsar had triumphed.—The temple of Peace was begun by the emperor Claudius, and finished by Vespasian, who embellished it with paintings and statues of the greatest masters, and also deposited in it all the spoils and riches taken by his son Titus in the temple of Jerusalem. It was burnt in the reign of Commodus.—The temple of Jupiter the Avenger was the *Pantheon*; which see. To the temples already enumerated, we might add those of Antoninus and Faustina, of Augustus, of Augustus and Bacchus, of the Muses, of Ceres, of Claudius Cæsar, of Concord, of Fame, of the Flavian family, of Faunus, of Fever, of Trajan and Neptune, of Happiness, of Faith and Jupiter the Preserver, of Flora, of Bad Fortune, of the eldest or first-born Fortune, of Public Fortune, of Virile or Courageous Fortune, of Hercules, of Juno, of Juno Moneta, of Juno Sospita, the giver or preserver of health, of queen Juno, of Jupiter Feretrius, of Jupiter Stator, of Jupiter Tonans or the Thunderer, of Jupiter the Conqueror, of Liber, an epithet of Bacchus, of the Mother of the gods, of Mercury, of Minerva, of the goddesses Nenia, of Ops and Saturn, of the Penates or Household gods, of Rest, of Quirinus, of Romulus and Remus, of Saturn, of Serapis, of the Sun, of the Sun and Moon, of the god Sylvanus, of Tellus or the Earth, of Venus, of Venus and Cupid, of Venus Erycina, of Venus Erycina and the Mind, of Venus Verticordia, of Vertumnus, of Veita, and many others, which, great and small, amounted to upwards of one thousand.

TEMPLE, *Jewish*, at *Jerusalem*; was an edifice erected much after the model of the tabernacle, but in a much more magnificent and expensive manner. According to the opinion of some, there were three different temples: the first built by David and Solomon on mount Moriah, which was part of mount Zion; the second, by Zerubbabel and Joshua the high priest; and the third by Herod. This last, however, the Jews will not allow to be a new temple, but only the second repaired or rebuilt. The expence of building Solomon's temple was prodigious: the gold and silver employed for this purpose amounted to upwards of eight hundred millions sterling (1 Chron. xxii. 14. xxix. 4. 6, 7.), which, says Dr. Prideaux, was sufficient to have built the whole temple with solid silver. But as the book of Chronicles was written after the return from the Babylonish captivity, it is probable that the Jews might compute by the Babylonish talent, which was little more than half the Mosaic talent, or perhaps by the Syriac talent, which was but one-fifth of the Babylonish; and thus the whole quantity of gold and silver would be reduced to a com-

paratively moderate quantity, and yet sufficient for the purpose.

Josephus (lib. vii. xiv. ii.) acquaints us, that the two first sums were only one-tenth part of what is expressed in the present Hebrew; and Dr. Kennicott (State of the Hebrew Text, vol. ii. p. 355.) thinks it probable, that a cipher was added to them both in some very ancient Hebrew copy.

This temple was surrounded, except at the front or east end, with three stories of chambers, each five cubits square, which reached to half the height of the temple; and the front was graced with a magnificent portico, which rose to the height of a hundred and twenty cubits. It was plundered by Nebuchadnezzar king of Babylon, and at length destroyed, after it had stood, according to Josephus, four hundred and seventy years, six months, and ten days, from its dedication. Others, however, as Calvisius and Scaliger, reduce the number of years to four hundred and twenty-seven, or four hundred and twenty-eight; and Usher, to four hundred and twenty-four years, three months, and eight days.

The second temple was built by the Jews, after their return from the Babylonish captivity, under the direction and influence of Zerubbabel their governor, and of Joshua the high priest, with the leave and encouragement of Cyrus the Persian emperor, to whom Judæa was now become a tributary kingdom. According to the Jews, this temple was destitute of five remarkable appendages, which were the chief glory of the first temple; viz. the ark and mercy-seat, the Schechinah, the holy fire on the altar, which had been first kindled from heaven, the urim and thummim, and the spirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes, who also caused the public worship in it to cease; and afterwards purified by Judas Maccabæus, who restored the divine worship: and after having stood five hundred years, rebuilt by Herod, with a magnificence approaching to that of Solomon's. Tacitus calls it *immense opulentia templum*; and Josephus says, it was the most astonishing structure he had ever seen, as well on account of its architecture as its magnitude, and likewise the richness and magnificence of its various parts, and the reputation of its sacred appurtenances. This temple, which Herod began to build about sixteen years before the birth of Christ, and so far completed in nine years and a half, as to be fit for divine service, was at length destroyed by the Romans on the same month and day of the month, on which Solomon's temple was destroyed by the Babylonians.

The Jewish temple itself consisted of the portico, the sanctuary, and the holy of holies; and it was ornamented with spacious courts, making a square of half a mile in circumference. The first court was called the court of the Gentiles, because they were allowed to come into it, but no farther. Within this was a less court, into which none but Israelites might enter, divided into the court of the women; and the inner court, in which the temple and altar stood, and into which the priests and all male Israelites might enter.

TEMPLE, in *Architecture*. The ancient temples were distinguished, with regard to their construction, into various kinds: as,

TEMPLE in *antæ*, *Ædes in antis*. These, according to Vitruvius, were the most simple of all temples, having only angular pilasters, called *antæ*, or *parastatæ*, at the corners, and two Tuscan columns, on each side of the doors.

TEMPLE, *Tetrapstyle*, or simply *tetrapstyle*, was a temple that had four columns in front, and as many behind. Such was the temple of Fortuna Virilis at Rome.

TEMPLE, *Prostyle*, that which had only columns in its front,

TEMPLE.

front, or fore-side. As that of Ceres at Eleufis, in Greece.

TEMPLE, *Amphyprostyle*, or *double prostyle*, that which had columns both before and behind, and which was alfo tetrastyle.

TEMPLE, *Pteriptere*, that which had four rows of insulated columns around, and was exhaftyte, *i. e.* had fix columns in front; as the temple of Honour at Rome. See PERIPTERE.

TEMPLE, *Diptere*, that which had two wings, and two rows of columns around, and was alfo octostyle, or had eight columns in front; as that of Diana at Ephesus.

TEMPLE, *Pseudo-diptere*. See PSEUDO-DIPTERE.

TEMPLE, *Hypæthros*. See HYPÆTHROS.

TEMPLE, *Monoptere*. See MONOPTERE.

TEMPLES, among us, denote two inns of court, thus called, because anciently the dwelling-house of the knights Templars.

At the suppression of that order they were purchased by some professors of the common law, and converted into hostia, or inns of courts.

They are called the *Inner* and *Middle Temple*, in relation to Essex-house, which was alfo a part of the house of the Templars, and called the *Outer Temple*, because situate without Temple-Bar.

In the *Middle Temple*, during the time of the Templars, the king's treasure was kept: as was alfo that of the kings of France in the house of the Templars at Paris.

The chief officer was the master of the Temple, who was summoned to parliament in 49 Hen. III. And from him the chief minister of the Temple church is still called *Master of the Temple*.

TEMPLE, Sir WILLIAM, in *Biography*, a statesman and miscellaneous writer, was the son of sir John Temple, master of the rolls in Ireland in the reign of Charles I. and II., and author of a History of the Irish Rebellion, and born in London in the year 1628. Having finished his course of classical education, he was entered, at the age of seventeen, at Emanuel college, in the university of Cambridge, under the tuition of the learned Cudworth. Being designed for public life, his principal attention at the university was engaged by the study of the modern languages, French and Spanish; and at the age of twenty, he was sent to finish his education by travelling on the continent. After spending six years in this way, he returned home in 1654, and married the daughter of sir Peter Osborn, of Chickland, Bedfordshire, with whom he became acquainted during his foreign travels. Declining to accept any office under Cromwell, he resided with his father in Ireland, and devoted his time to the study of history and philosophy. At the Restoration he became a member of the Irish Convention; and in the Irish parliament of the year 1661, he was returned as a representative of the county of Carlow, and in 1662 was nominated one of the commissioners from that parliament to the king. At this time he removed with his family to England; and having faithfully executed a secret commission to the bishop of Munster, with which he was entrusted in 1665, he was appointed in the following year resident at the court of Brussels, and raised by patent to the rank of a baronet. During the reign of Charles II. he was concerned in a variety of negotiations. After the peace of Breda, (July 10, 1667,) sir William went over to Holland, and formed an intimate acquaintance and friendship with De Wit, a man frank and open, and of the same generous and enlarged sentiments with himself; and in consequence of the negotiations of these two able statesmen, a defensive alliance was concluded between Holland and England. Sweden acceded to the confederacy: and thus was

formed the triple league, which was generally regarded with equal surprize and approbation. In the conduct of this business, Temple acquired great honour; but to all the compliments that were paid to him on the occasion, he modestly replied, that to remove things from their centre, or proper element, required force and labour; but that of themselves they easily returned to it. The French monarch and the court of Spain were equally displeas'd; but in the treaty at Aix-la-Chapelle, where Temple appeared as ambassador extraordinary and mediator, on behalf of England, his address prevailed; the Spanish minister complied with the conditions propos'd; and the peace between the contending powers was signed in May, 1668. In consequence of this event, sir William was nominated ambassador to the States-General, and taking up his residence at the Hague in the month of August of this year, he maintained his intimacy with De Wit, and was also on familiar terms with William, prince of Orange, who had then attained the age of eighteen years. But this triple alliance was of short duration. The corruption and intrigues of the English court produced a recall of Temple in the year 1669, and when it was propos'd to him to return and make way for a breach with Holland, he declined, much to his honour, engaging in hostility against a country to which he was attached, and retired from public business to his seat at Sheen, near Richmond. Here he employed himself in the improvement of his mansion, and in the cultivation of his garden; and also in writing his "Observations on the United Provinces," and a part of his "Miscellanea." When the war with the Dutch became unpopular through the nation, and the court and its ministers were under a necessity of bringing it to a termination, sir William Temple was called out of his retirement to negotiate with the Spanish minister in London: and when the separate peace with Holland was concluded, he was request'd in the next year, 1674, to undertake the office of ambassador to the States-General, for the purpose of negotiating a general peace. Before his acceptance of this office, he obtained an audience of the king, with a view of stating to his majesty the pernicious politics of the Cabal ministry, and the necessity of popular measures for regaining the confidence of the nation. The negotiations for peace were commenced at Nimeguen, whither he removed from the Hague in 1676: and during their slow progress, he availed himself of the opportunity thus afforded him for accomplishing the popular measure of the marriage of the prince of Orange to the duke of York's eldest daughter, which took place in 1677. On another occasion, when the French manifested their intention of retaining the Spanish towns, which were to be surrendered by treaty, Temple was dispatched to the Hague to concert effectual measures with the States for bringing the French to terms; and in six days he concluded a treaty, July 10, 1678, by which England was bound to declare war against the French if the towns were not evacuated within the interval of sixteen days; but so feeble and fluctuating were the English councils, that before the ratification of the projected treaty, peace was signed at Nimeguen, and France was secured in the possession of a great part of its conquests.

In 1679 Temple was recalled from the Hague, in order to be appointed one of the secretaries of state; but perceiving the violence of parties, and the prevalence of discontent, he recommended a council of thirty persons, which was to be compos'd, together with the ministers of the crown, of persons possessing influence and credit in both houses of parliament. But divisions occurred which prevented the salutary effects of such a measure. Projects of limitation or exclusion were the subjects of warm discussion in parliament.

To these measures Temple was adverse; and his last act in parliament, as member for the university of Cambridge, was to carry from the council the king's final answer to the address of the Commons, never to consent to the exclusion of his brother: other members had previously declined this disagreeable service. When the king, in January 1681, dissolved the parliament without the advice of his privy council, Temple boldly remonstrated against the measure; and at length, wearied with the faction and misgovernment which he had witnessed, he declined the offered return for the university to the new parliament, and retired to Sheen, conveying from thence a message to the king, "that he would pass the rest of his life as good a subject as any in his kingdom, but would never more meddle with public affairs." The king replied to the message, that he bore him no resentment; but his name was expunged from the council. The remainder of his life was spent in retirement and seclusion from all public business; and it is said, that he interfered so little in political matters, as not to know the design of the prince of Orange to engage in the expedition that terminated in the revolution, and to be the last person who gave credit to his landing. After James's abdication, however, he waited on the prince at Windsor, and presented to him his son. King William urged upon him the acceptance of the office of secretary of state; but he maintained his purpose of living in retirement. His son was appointed secretary at war; but in the week in which he assumed the office, he was seized with melancholy, and threw himself into the Thames. His reflection on this afflictive event was that which his Stoic philosophy alone could have dictated: "a wife man might dispose of himself, and render his life as short as he pleased." In his state of retirement, he admitted Swift to be his companion, as we have already mentioned under SWIFT's article. King William occasionally visited him, and confidentially consulted him on several important affairs. In 1694 he lost his wife; and sinking gradually under increasing infirmities, occasioned by repeated fits of the gout, his life was terminated at Moor park, in January 1698, in his 70th year. The greatest part of his fortune was bequeathed to the daughters of his unfortunate son by a French lady, under the express condition that they should not marry Frenchmen.

Sir William Temple ranks high as a statesman, and also as a patriot, who well understood and zealously pursued his country's interest. His foibles, without giving them a worse appellation, were impatience with those whom he disliked, warmth in dispute, and a share of vanity and conceit; but he was substantially, says his biographer, a worthy man in the various relations of life. To outward forms of religion he paid little regard; but his letter to the countess of Essex is no less pious than eloquent: so that we can scarcely admit the charge of atheism with which he is reproached by bishop Burnet. As a writer, he ranks among the most eminent and popular of his time. His "Observations upon the United Provinces of the Netherlands" were printed in 1672, and deserve the attention of the politician and philosopher: his "Miscellanæ" are lively and entertaining, if not profound. His "Memoirs" elucidate the history of the times. His "Introduction to the History of England" was published in 1695. His "Letters," in 3 vols., which relate to public transactions, were published after his death by Swift. "All sir William Temple's writings," says one of his biographers, "display much acquaintance both with books and men, and are entirely free from the licentiousness so prevalent in that age. Their style is negligent and incorrect, but agreeable, resembling that of easy and polite conversation." Hume's Hist. vol. vii. Svo.

Biog. Brit. Gen. Biog. Account of his Life, &c. prefixed to the folio edition of his Works, in 2 vols. Lond. 1720.

Sir William Temple did not escape the lash of criticism, and such was his vanity or irritability, or perhaps a composition of both, that his indignation was roused, and he expressed himself in the following terms: "The critics are a race of scholars I am very little acquainted with; having always esteemed them but little brokers, who, having no stock of their own, set up and trade with that of other men, buying here and selling there, and commonly abusing both sides, to make out a little paltry gain, either of money or credit, for themselves, and care not at whose cost." In another place he says, "there is, I think, no sort of talent so despicable, as that of such common critics, who can at best pretend to value themselves by discovering the defaults of other men, rather than any worth or merit of their own:—a sort of levellers, that will needs equal the best and richest of the country, not by improving their own estates, but reducing those of their neighbours, and making them appear as mean and wretched as themselves."

TEMPLE, in *Geography*, a town of the province of Maine, in the county of Kennebeck, containing 482 inhabitants.—Also, a township of New Hampshire, in the county of Hillsborough, containing 941 inhabitants; 70 miles W. of Portsmouth.

TEMPLE, *Le*, a town of France, in the department of the Lot and Garonne; 7 miles W. of Villeneuve d'Agen.

TEMPLE Bay, a bay on the N.E. coast of New Holland, to the S. of Cape Grenville.—Also, a bay on the E. coast of Labrador. N. lat. 52° 25'. W. long. 55° 50'.

TEMPLEMORE, (*i. e. the Great Church*), a post-town of the county of Tipperary, Ireland, where there was formerly held a fair for wool, which lasted several days. It is 75 miles S.W. from Dublin.

TEMPLE PATRICK, (*i. e. Patrick's Church*), a post-town of the county of Antrim, Ireland, on the river Six-mile-water; 4½ miles E. by S. from Antrim, on the road to Belfast.

TEMPLERS. See *TEMPLARS*.

TEMPLES, in *Anatomy*. See *TEMPORA*.

TEMPLETON, in *Geography*, a town of America, in the state of Massachusetts, and county of Worcester, containing 1203 inhabitants.

TEMPLETONIA, in *Botany*, is dedicated by Mr. R. Brown, to the honour of John Templeton, esq. of Orange Grove, near Belfast, a gentleman whose enquiries have much enriched our knowledge of Irish plants, and whose name consequently often appears in the pages of the *Flora Britannica* and *English Botany*.—Brown in Ait. Hort. Kew. v. 4. 269.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, simple, bell-shaped, with five rather unequal segments in the limb, permanent. *Cor.* papilionaceous, of five petals. Standard elliptical, ascending, entire. Wings nearly the length of the standard, linear-oblong, obtuse, with a small tooth near the base at their upper edge. Keel a little shorter than the wings, oblong, slightly curved, of two half-ovate petals, cohering near the extremity, with short claws. *Stam.* Filaments ten, all combined into one tube for more than half their length, separate above, ascending, five alternate ones rather the shortest; anthers uniform, small, oblong, incumbent. *Pistl.* Germen stalked, linear-awlshaped; style awlshaped, ascending; stigma capitate. *Peric.* Legume stalked, linear-oblong, compressed, obliquely pointed, of one cell and two valves. *Seeds* eight or ten, oval, polished, the scar of each bordered with a prominent crest.

Effl. Ch. Calyx simple, with five rather unequal teeth.

Keel

Keel oblong. Stamens all connected. Anthers uniform. Legume stalked, compressed. Seeds numerous, crested.

1. *T. retusa*. Wedge-leaved Templetonia, Ait. n. 1. (*Rafnia retusa*; Venten. Malmaif. t. 53.)—Gathered by Mr. Brown, on the fourth-west coast of New Holland, from whence seeds were sent to England by Mr. Peter Good, in 1803. This is a greenhouse shrub, flowering in spring and summer. *Stem* about a yard high, with straight, angular, smooth, leafy branches. *Leaves* about an inch and half long, alternate, on short stalks, spreading, entire, emarginate, smooth. *Stipulus* in pairs, small, oval, deciduous. *Flowers* lateral, axillary, solitary, on simple stalks, which are rather shorter than the leaves. *Calyx* destitute of the imbricated appendages which make a principal part of the character of the neighbouring genus *SCOTTIA*. (See that article.) *Petals* near an inch long, of a deep crimson. *Legume* two inches long, and half an inch broad, slightly tumid where each seed is lodged.

TEMPLEUVE *en Pessule*, in *Geography*, a town of France, in the department of the North; 7 miles S.S.E. of Lille.

TEMPLIN, a town of Germany, in the Ucker Mark of Brandenburg, situated between the Bodensee and Dolgensee. In the year 1735, this place was totally consumed by fire, but has been rebuilt to very great advantage; its streets being now broad and straight, and its houses uniform, exclusive of a spacious market-place in it, which forms a regular quadrangle, inasmuch that at present it is one of the most beautiful towns in all the Mark. It carries on a very large trade in timber, which is greatly promoted by means of a canal, newly made. In 1806 it was taken by the French, under the duke of Berg; and the prince of Hohenloe, who had retired hither after the battle of Jena, was made prisoner; 15 miles S.W. of Prenzlau. N. lat. 53° 5'. E. long. 13° 34'.

TEMPLUM SOSTRATI, the name of a kind of surgical bandage described by Galen. He also describes another, under the name of *templum parvum Apollonii Tyrii*.

TEMPO, Ital., time, or measure, in *Music*.

TEMPO Ordinario, usual time.

TEMPO di Gavotta, gavot time. See GAVOTTA.

TEMPO di Minuetto, minuet time.

A TEMPO, or *à tempo primo*, after a pause, or *rallentando*, or *ad libitum*, implies a return to the first time in which a movement is begun; and in recitative, where, in general, no time is kept, *à tempo*, in an accompanied recitative, implies a regular time.

TEMPOAL, in *Geography*, a town of Mexico, in the province of Guafteca; 50 miles S.E. of St. Yago de los Valles.

TEMPORA, in *Anatomy*, the anterior and lateral parts of the head, where the skull is covered by the temporal muscles: the temples in common language. See CRANIUM.

TEMPORAL, TEMPORALIS, a term frequently used for *secular*. In which sense it stands opposed to *ecclesiastical*.

Pope Boniface wrote to Philip the Fair of France, that he was subject to him, both in spirituals and temporals.

At present, all the doctors on this side the Alps own the supremacy of kings in temporals.

TEMPORAL Action. See ACTION.

TEMPORAL Augment. See AUGMENT.

TEMPORALIS, TEMPORAL, in *Anatomy*, an epithet applied to various parts about the temples; these are a superficial, a middle, and two deep-seated temporal arteries; a temporal bone on each side of the head; a temporal vein;

a temporal muscle; and temporal nerves. See the respective articles.

TEMPORALITIES, or TEMPORALITIES, the temporal revenues of an ecclesiastic; particularly such lands, tennements, or lay-fees, tithes, &c. as have been annexed to bishops' sees by our kings, or other persons of high rank in the kingdom. See REVENUE.

The temporalities of a bishop, &c. stand opposed to his spiritualities. See VACATION.

The canonists on the other side of the Alps, anciently gave the pope a power over the temporalities of kings. Yet pope Clement V. owned frankly, that his predecessor Boniface VIII. had exceeded the just bounds of his authority, in meddling with the temporalities of the king of France. Fevret.

TEMPORALIUM CUSTOS. See CUSTOS and VACATION.

TEMPORALIUM Restitutio. See RESTITUTIO.

TEMPORARY FORTIFICATION. See FORTIFICATION.

TEMPORARY Hours. See HOUR.

TEMPOREGIATO, in the *Italian Music*, sometimes signifies, that the musicians who accompany the voice, or the person who beats time, should prolong some particular part thereof, to give the actor or singer room to express the passion he is to represent, or to introduce some graces, by way of ornament to the piece.

TEMPOREGIATO is also used in a different sense, for *à tempo*, or *à tempo giusto*.

TEMPORUM OSSA, in *Anatomy*, two bones of the cranium. See CRANIUM.

TEMPSCHE, in *Geography*, a town of France, in the department of the Scheld; 10 miles S.W. of Antwerp.

TEMPTATION, TENTATIO, in *Theology*, an induction or solicitation to evil, whether arising from the world, the flesh, or the devil.

Our Saviour's temptation, previous to the commencement of his public ministry, has been a subject of discussion and controversy among learned divines.

The evangelical account of this transaction may be found in Matt. iv. 1—11. Mark, i. 12, 13. Luke, iv. 1—12. It has generally been supposed, that the evangelical history of our Lord's temptation is to be understood as a narrative of outward transactions: that the devil tempted Christ in person, appeared to him in a visible form, spoke to him with an audible voice, and removed him corporeally from one place to another; and it must be allowed that these suppositions are warranted by the literal interpretation of the history. Nevertheless, this interpretation is liable to a variety of objections. It is unsuitable to the sagacity and policy of the evil spirit. Why, it has been suggested, should the devil assault our blessed Lord at all, and what advantage could he expect to gain over him; more especially when he came to him in person, and appeared before him in a visible form, and under his own proper character, proposing and urging temptations which could proceed only from an evil being? In order to evade this difficulty, some writers, as archbishop Secker and Dr. Chandler, have conjectured that the devil appeared *not as himself*, but under the assumed resemblance of a good angel; and others have supposed that he appeared to Christ in the form of a man. But the history furnishes no ground for these conjectures, and they are equally inconsistent with the temptations themselves, considered in their own nature; nor can it be pretended that Christ was ignorant by whom the several temptations, and particularly the third of them, was proposed; for in his reply, he calls him Satan. Besides, this transaction, according to the literal interpretation of its history, was very ill calculated to promote either the honour

TEMPTATION.

of Christ, or the instruction and consolation of his disciples. This objection is strengthened, when we consider, that Christ must have yielded voluntarily to the mere motion and instigation of the devil, and have been accessory to his own dishonour, danger, and temptation. His character must have been rather degraded than exalted. The temptations presented to Christ were such in their own nature as could not afford evidence or exercise of his obedience, nor of course suitable consolation or useful instruction to his followers, under real and powerful trials. Moreover, it has been objected to the common opinion, that it ascribes to the devil the performance of the greatest miracles, and of things not only preternatural, but absurd and impossible, for such we must regard his shewing Christ all the kingdoms of the world from an exceedingly high mountain, and also whatever constitutes the glory and grandeur of its kingdoms. If we are under a necessity of deviating from a literal, and of adopting a figurative interpretation of the transaction recorded in this history, we are warranted in so doing by other instances of a similar kind, that occur in the sacred writings. These writings relate things as actually done, which nevertheless were only transacted in a vision. Cases of this kind frequently occur in scripture; for which we might refer to Genesis, xxxii. 30. Hosea, i. and iii. Jeremiah, xiii. xxv. xxvii. Ezekiel, iii. iv. v. St. Paul calls his "being caught up into the third heaven" and "into Paradise, a vision and revelation of the Lord." (2 Cor. xii. 1—4.) In conformity to these general principles, some writers of eminence have proceeded in forming their judgment concerning the temptations of Christ; and constrained by such objections as we have already briefly stated, they have abandoned the opinion that these temptations are to be understood as outward transactions, inasmuch as the things themselves were improbable, and even impracticable in their own nature; and inasmuch as the real performance could answer no valuable purpose. Calvin allows, in his note on Matt. iv. 5, that several circumstances in this history agreed best to a vision; and the generality of later writers have admitted, that the devil's shewing to Christ all the kingdoms of the world, and all their glory, in a moment of time, was done by some fictitious scenery, from a persuasion, that it could not be done in any other way. Hence it has been argued by others, that if one of the temptations were presented to Christ in vision only, why might not the two others be presented to him in the same manner. Adverting to the history itself, it is alleged, that the text, instead of positively and expressly asserting that the temptation of Christ was a real outward transaction, contains clear intimations, and even direct assertions of the contrary. Thus, in the passage relating to the exhibition of the kingdoms of the world, and all their glory, in one view, and in a single point of view, the evangelist is not speaking of the real sight of all these objects; but he must design to be understood of what was instantaneously exhibited to the mind. Other plain intimations occur, that Christ's temptation is not to be understood as an outward transaction; and it is alleged by the advocates of this opinion, that all the evangelists who have mentioned this affair, do, in express terms, affirm that it passed *spiritually*, and in *vision*, or that it was merely an ideal or mental representation.

Some of those biblical critics, who consider this history as a recital of visionary representations, maintain that these visions were framed by the devil, and that the temptations are to be ascribed to his immediate agency: thus denying the power of Satan over the body of Christ, and granting him a nobler empire, a sovereign influence over the mind. Some have indeed supposed that Christ's temptation was nothing

more than a bare *meditation* of our Lord upon such trials as might possibly be proposed by the great tempter of mankind. But it is needless to make any observations on a view of the subject, which is altogether unsupported by the history.

Another opinion has been proposed by a very able writer, in favour of which he has adduced a variety of arguments, that have given satisfaction to many persons who have examined this subject. Mr. Farmer (in his Inquiry into the Nature and Design of Christ's Temptation in the Wilderness) represents our Lord's temptation as befalling him while he was under a prophetic vision, of which the Spirit of God himself was the immediate and sole author. Accordingly he considers the temptation of Christ, neither as an outward transaction, nor diabolical delusion, but as a divine vision. At the time when this event occurred, our Saviour was actually in the wilderness, and therefore when the evangelist says, that "Jesus was led up of the Spirit into the wilderness," or as our author more literally renders the words, "then was Jesus brought (or carried) into the wilderness by the Spirit," he intimates, that into a wilderness our Lord seemed to himself to be carried, or thither he was transported in vision by a prophetic divine afflatus. The expressions used by the other evangelists, Mark and Luke, are said to confirm the explication thus given of the language of St. Matthew. Upon the whole, the meaning of the evangelists will be, "Christ was brought into a wilderness (not merely under a divine direction, but) under the full influence of the prophetic Spirit, making suitable revelations to his mind, and giving him a view particularly of his future trials." And these trials are described as "temptations of the devil," on account of the particular mode of their being revealed, being couched under the figure of Satan coming to him, and urging temptations. Our author, proceeding to examine the proper intention of this prophetic vision, observes, that the several scenes which it comprehends, though presented to Christ in the form, and capable of answering the end, of a present trial, were directly intended as a symbolical prediction and representation of the future difficulties of his office and ministry. The first scene in Christ's vision was probationary, serving to discover the present turn and temper of his mind; and also prophetic, having a reference to his future ministry, through the whole course of which he was pressed with the same kind of temptations, and resisted them upon the same principles. This part of the vision, therefore, conveyed this general instruction: "that Christ, though the son of God, was to struggle with the afflicting hardships of hunger and thirst, and all the other evils of humanity, like the lowest of the sons of men; and that he was never to exert his divine power for his own personal relief, under the most pressing difficulties, or for the supply of his most urgent occasions; but with resignation and faith to wait for the interposition of God in his favour." The second scene of this vision was Jerusalem, the metropolis of Judea and the seat of power; it was the temple of Jerusalem, where the Jews expected the first appearance of their Messiah; it was the wing of the temple, the eastern front of it, which commanded a view of the worshippers below. From this eminence Christ is required to throw himself down, in a dependence upon the divine protection, that so his miraculous preservation might give evidence of his divine mission, and induce the numerous worshippers, who were eye-witnesses of it, to acknowledge him immediately as the Messiah, visibly descending from heaven, in a manner agreeable to the expectation of the Jews. Such was the proposal, and the temptation was powerful. The principle upon which he rejected it was, in its spirit and meaning, this: "the Scripture forbids us

to prescribe to God in what instances he shall exert his power; and as we are not to rush upon danger without a call, in expectation of an extraordinary deliverance; so neither are we to dictate to divine wisdom what miracles shall be wrought for men's conviction." As this trial bore reference to his future ministry, we find that in exemplifying the principle now manifested, he never needlessly and unwarrantably exposed himself to danger, and then relied on a miraculous interposition of divine power for his rescue; but he was cautious in declining hazards; avoiding what might exasperate his enemies; and even enjoining silence with regard to his miracles, when the publication of them was likely to excite envy or popular commotion, and to inflame their minds against him. In displaying the evidences of his divine mission, he still acted upon the same maxim, opening his commission, not at Jerusalem, but in Galilee. In order to avoid ostentation and offence, he kept himself as private as the object of his commission would allow; and instead of courting the favour of the opulent and powerful, he conversed freely with all sorts of people. In many other instances which an attentive perusal of his history will furnish, his ministry will correspond to his prophetic vision, in which he was tempted to a public and ostentatious display of his miraculous powers. In the third scene, the proposal was instantaneously rejected, and not without a mixture of just indignation. Besides this trial of his temper, the scene before us pre-signified the temptation to which he would be exposed in the course of his future ministry, during which he was called upon to prostitute himself, with all his miraculous endowments, to the service of Satan, for the sake of worldly honours, or for gratifying the mistaken expectations of the Jewish people. For a farther illustration of this subject, we must refer to the work already cited. See also archbishop Secker's, Dr. Clarke's, Dr. Chandler's, Mr. Mason's Sermons, on this subject. Benson's History of the Life of Christ. Macknight's Truth of the Gospel History.

TEMPTATION, *Temtatio*, in our *Ancient Law-books*, is used for a trial, proof, or assay. "Tentatio panis fiat bis in anno." Chart. Edw. I. See **ASSAY**, &c.

TEMROOK, in *Geography*, a famous station in the Crimea, situated at the foot of a small mountain, near the northern embouchure of the Kuban. It is now a single hut, for the purpose of supplying post-horses. In Motraye's time, who travelled this way in December 1711, it was a place of greater importance. He describes it as considerable for its commerce in hides, caviare, honey, Circassian slaves, and horses. He supposed that its castle stood where the ancients placed their "Petraeus;" and two eminences, he says, which are named "the point of the island," may have been their "Achilleum Promontorium." This, it is supposed, was the situation of Cimmerium. Pallas conjectures, that Temrook may probably have been the "Cimbricus" of Strabo.

TEMS, Fr., *time*, in *Musick*; as *à contre tems*, against time.

TEMSENA, in *Geography*, a province of Morocco, situated on the coast of the Atlantic, to the S. of Sallec. This province is rich and fertile, and abounds in excellent provisions, of various kinds. Its name seems intended to signify its salubrity, and the purity of the climate. Temfena appears to be derived from the two Arabic words *Tamam Sana*, *only a year*; as if they should say, that to reside here only a year would be sufficient to insure the sickly the return of their health, and such, in fact, is the firm belief of the natives. Corn is very plentiful in this province; it is of a very excellent kind, and the ears frequently bear 70 grains, or more. In the forests is found a kind of cedar, called *hazar*, of a

resinous smell; it is a hard and incorruptible wood, and the Moors employ it in building their houses.

This and the neighbouring provinces abound in horses and horned cattle; their flocks are numerous, and the cavalry of Temfena is the best appointed of the empire, excepting the Black troops of the emperor, called Abee Seedy Buharrie. The population of the districts of Temfena and Shawia is estimated at 1,160,000 persons. The males of Temfena and Shawia are a strong, robust race, of a copper colour; their women possess much beauty, and have highly expressive features; and the animation of the countenance is increased by the use of *el kokol* filely, with which they tinge their eye-lashes and eye-brows. In these provinces they are fond of dyeing their hands and feet with a preparation of the herb henna, which gives them a beautiful orange-colour, and, in hot weather, imparts a pleasing coolness and softness to the hands, by preventing, in a considerable degree, the quickness of perspiration.

TEMUS, in *Botany*, a genus which Jussieu has condescended to adopt, by its barbarous name, from the hardly less barbarous information of Molina. Juss. Gen. 435.—Class and order, *Polyandria Digynia*. Nat. Ord. uncertain.

Ess. Ch. "Calyx three-cleft. Petals eighteen, linear, very long. Stamens twenty-six, shorter than the petals. Anthers globose. Germens two. Styles two. Berry two-lobed. Seeds tunicated."—Native of Chili, where it is called *Temo*. This it seems is an evergreen tree, with alternate leaves, and stalked terminal flowers.

TEMUS, in *Geography*, a river of Sardinia, which runs into the sea, 4 miles E. of Castello Arragonefe.

TENA, a town of South America, in the province of Quito; 15 miles S. of Archidona.

TENABLE, formed from the French *tenir*, and that from the Latin *tenere*, to hold, in the *Military Art*, something that may be defended, kept, and held, against assailants.

Tenable is little used, but with a negative: when a place is open on all sides, and its defences are all beaten down, it is no longer tenable. When the enemy has gained such an eminence, this post is not tenable.

TENACIOUS BODIES. See **TENACITY**.

TENACITY, in *Natural Philosophy*, that quality of bodies by which they sustain a considerable pressure, or force, without breaking. Mem. Acad. Berlin, 1745, p. 47.

Tenacity is the opposite quality to fragility, or brittleness.

TENACULUM, in *Surgery*, an instrument used in amputation, for pulling out bleeding vessels that are to be tied by ligatures.

TENAGLIA, in *Biography*, a Roman composer, mentioned by Pietro della Valle, as having set the opera of "Clearco," for that city, about 1634. This seems to have been one of the first musical dramas performed at Rome in a public theatre.

TENAILLE, in *Fortification*, a kind of outwork, consisting of two parallel sides, with a front, in which is a re-entering angle.

In strictness, that angle, and the faces which compose it, are the tenaille.

The tenaille is of two kinds; *simple* and *double*.

TENAILLE, Simple, or *Single*, is a large outwork, consisting of two faces or sides, including a re-entering angle. See *Plate V. Fortification, fig. 4. lit. d.*

TENAILLE, Double, or *Flanked*, is a large outwork, consisting of two simple tenailles, or three salients, and two re-entering angles. *Fig. 21. lit. e.*

The great defects of tenailles are, that they take up too

much room, and on that account are advantageous to the enemy; that the re-entering angle is undefended; the height of the parapet hindering the seeing down into it, so that the enemy can lodge there under covert; and the sides are not sufficiently flanked.

For these reasons, tenailles are now excluded out of fortifications by the best engineers, and never made, but where there wants time to form a horn-work.

TENAÏLLE of the Place, is the front of the place, comprehended between the points of two neighbouring bastions; including the curtain, the two flanks raised on the curtain, and the two sides of the bastions which face one another.

So that the tenaille, in this sense, is the same with what is otherwise called the *face of a fortress*.

TENAÏLLE of the Ditch, is a low work raised before the curtain, in the middle of the foss or ditch; the parapet of which is only two or three feet higher than the level ground of the ravelin.

There are three different forts (*Plate VII. Fortification, fig. 6.*) The first are those which are made in the direction of the lines of defence, leaving a passage of three toises between their extremities and the flanks of the bastions, and likewise another of two toises in the middle for a bridge of communication to the ravelin. The second (*fig. 7.*) are those whose faces are in the lines of defence, and sixteen toises long, besides the passage of three toises between them and the flanks of the bastions: their flanks are found by describing arcs from one shoulder of the tenaille as a centre through the other, on which are set off ten toises for the required flanks. The third fort (*fig. 8.*) comprehends those whose faces are sixteen toises, as in the second fort, and the flanks parallel to those of the bastions.

The use of tenailles, in general, is to defend the bottom of the ditch by a grazing fire, and likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which cannot be so conveniently defended from any other place. The first fort do not defend the ditch so well as the others, because they are too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places. Those of the second fort defend the ditch much better than the first, and add a low flank to those of the bastions; but as these flanks are liable to be enfiladed, they have not been much used. This defect, however, might be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work. Those of the third fort have the same advantage with the second, and are subject to the same inconveniences; and, therefore, they may be used with the same precaution.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them, and it is not without reason; for when the ditch is dry, the part behind the tenailles serves as a place of arms, from which the troops may sally, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure, which is a great advantage; for by that means the ravelin may make a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please; and the communication from the tenailles to the ravelin becomes likewise much easier than it would be without them. Muller's Elem. of Fort. p. 34. See FORTIFICATION.

The ram's-horn is a curved tenaille, raised in the foss before

the flanks, and presenting its convexity to the covered way. This work seems preferable to either of the other tenailles, both on account of its simplicity, and the defence for which it is constructed.

TENAÏLLONS, are works constructed on each side of the ravelin, much like the lunettes: they differ, as one of the faces of a tenaillon is in the direction of the ravelin, whereas that of the lunette is perpendicular to it.

Tenaillons are constructed by producing the faces of the ravelin beyond the counterscarp of the ditch, at a distance MN (*Plate VII. Fortification, fig. 9.*) of thirty toises, and taking on the counterscarp of the great ditch fifteen toises from the re-entering angle p to q , and drawing Nq ; then $qNMp$ will be the tenaillon required; its ditch is twelve toises, or the same as that of the ravelin. Sometimes there is made a retired battery, in the front of the tenaillons, as at B: this battery is ten toises from the front, to which it is parallel, and fifteen toises long. There are commonly intrenchments made in the tenaillons, such as O; their parapets are parallel to the fronts MN, or rather perpendicular to the side Nq , and bisect the side qN ; the ditch before this retrenchment is three toises, and there is a banquette before the parapet, next to the ditch, of about eight feet, called *berm*, serving to prevent the earth of the parapet (which seldom has any revetement) from falling into the ditch. The ravelin, before which tenaillons are constructed, must have its salient angle much greater than the former construction makes them; otherwise the salient angles of the tenaillons become too acute; for which reason the capital of this ravelin is made forty-five toises, and the faces terminate within three toises of the shoulders. Muller's Elem. Fort. p. 37.

A tenaillon is a work capable of affording great defence to the besiegers; as at the siege of Lille, in 1708, where the besiegers were twice or thrice drove out of a tenaillon they had taken and retaken.

TENALA, in *Geography*, a town of Sweden, in the province of Nyland; 8 miles N.W. of Eknas.

TENANCY, a habitation, or house to live in, or a tenement or possession held of another.

TENANCY, Entire. See ENTIRE.

TENANCY in Tail. See FEE-TAIL.

TENANT, in *Agriculture*, a person holding land or other property of another, either by grant, lease, or otherwise. Tenants are of different kinds, according to the nature of the tenures by which they hold their lands; but, in this last respect, they properly belong to the business of the law. Tenants hold their lands or farms for very different lengths of time, in different districts, as from one year to twenty-one; but in many places they have no leases at all. The most common lengths of time are seven, nine, fourteen, nineteen, and twenty-one. Short leases are now becoming general, as those of seven, nine, and eleven years. Tenants now mostly pay all taxes, except that on property.

The proper choice of tenants is a matter of the greatest importance to the well-doing and continued prosperity and success of all sorts of landed property, of almost any that can be adopted; as where they are improperly provided, there can hardly any thing go on in the manner which it ought to do; nor can there be the best sort of management, that the case will admit of, pursued. Many things will necessarily run into complete neglect, and ruinous states of them be produced as the consequence, which might have been easily and wholly avoided, by more attention in the first selection of the tenants.

The writer of the Middlesex Agricultural Report, after inculcating the necessity and utility of tenants having good

and properly regulated leases of the lands which they hold, remarks, that the letting of farms to tenants at will, or from year to year, is a most unwise practice, and one which should by all means be avoided by the proprietors of landed estates; as such tenants, he contends, from the very nature of their tenures, are precluded from the possibility of making any improvements; while they have it in their power to ruin the lands they occupy and hold. Rapacious landlords, unskilful stewards, and yearly tenancy, it is continued, destroy the holders' or tenants' confidence, smother their thoughts of improvements, and, in short, make bad tenants, by setting them to contrive some mode of occupying the lands, so as to be able to quit them, on receiving half a year's notice, with the least possible loss to themselves; and which can only be done, by keeping the soil continually in a poor state, to the evident great losses of the proprietors, the no less ones of the tenants, and the still more disadvantages of the community in general. See LEASE, LETTING of Farms, and QUALIFICATIONS of Tenants.

The writer of the work on "Landed Property" has remarked that, on all large estates, there are certain established customs and usages to which the proprietors, as well as the tenants or occupiers, consider themselves mutually amenable, although no legal contracts may subsist between them; and that, even where imperfect leases, or other legal agreements, exist, there is still, in general, much left for custom and usage to determine. These fixed regulations, though they may be imperfect, it is contended, should be strictly regarded by superintendents, until better ones are substituted in their place, not only for the sake of moral justice, but as setting an example of integrity and good faith to the tenants. Nothing of this sort should ever be broken through by those in the management of such properties; as tenants on all such are constantly to be met with ready enough to break their stipulated agreements, without such examples; and it must be extreme folly to induce the others who are well disposed to do the same. On the contrary, it is but common prudence to fulfil every covenant, agreement, and promise, which may have been made, with the most scrupulous exactness, even to the meanest cottager, in order to inspire proper confidence, and obviate much mischief.

And besides setting examples of these kinds before the tenants, they ought, it is supposed, to be liberalized in their minds, by good offices, and acts of kindness, which may be beneficial in various ways. A spirited improving tenant should be refused few reasonable demands: he should have advantages conferred on him, not merely as rewards for his labours in benefiting the lands, but as inducing other tenants to pursue similar plans, and to shew that good managers are noticed and distinguished.

The consequences of an inattention to these matters, which is too common in most parts of the country, are very prejudicial; as the refusing of requests which would equally benefit the estate and the tenant, the stupidly thwarting of the well-meant intentions of the best tenants upon it, the ignorantly quarrelling with them about mere trifles, and the making no sort of difference between those who are improving and those who are ruining it, or perhaps the encouraging the latter, and opposing the former, must have effects of the worst kind, there can be no doubt. Such tenants as are capable of improving, are also capable of impoverishing; and when disgusted by improper treatment, will be sure to harass the lands they hold, and take the first chance they have of removing to farms under more rational management, to the great inconvenience and disadvantage of those which they held before.

It is observed in the Agricultural Survey of Gloucester-

shire, that the leases of rack-renters there generally commence at Lady-day; and, in this case, in the vale, the going-off tenant holds a part of the grass-lands to old May-day, and has likewise the going-off crop of wheat, with the use of the barns for the purpose of housing and threshing it, till the Midsummer following. In this usage there is, the writer thinks, great inconvenience, especially where the new tenant is at variance with the old one, which is not uncommonly the case. Each has an opportunity of distressing and incommoding the other in various ways. The improved spirit of agriculture has discovered, both to landlord and tenant, the absurdity of this ancient custom; and it is gradually falling into disuse. Where an improvement has taken place, the coming-on tenant enters the preceding Michaelmas to plough the land for spring-crops; the tenant going off at Lady-day ploughs for the wheat-crop, and often sows it. In the case of ploughing only, the work is paid for; and when sowed, the crop is valued at Lady-day, and paid by the coming-on tenant. The going-off tenant is also frequently paid for his seeds left after the last year's crop. Under this practice, the new tenant enters on the whole of the estate at Lady-day. And it is added, that Michaelmas takings are not uncommon; though, in one respect, they are particularly inconvenient, as the old tenant has no time to spend the crops of the preceding summer on the premises, and the new tenant is either obliged to sell his flock at a most unfavourable time, or purchase fodder for the support of it at his new farm; a circumstance he cannot always command, and, when he can, at great loss. But there are other takings which commence at Candlemas, which have some inconveniences, particularly that of enabling the new tenant to "hain up" his pastures early, which is a matter of considerable consequence; for the old tenant, going off at Lady-day, always stocks as far as he can till the last moment, thereby leaving the ground as bare as possible. Nor is the mischief of this late *haining* always compensated by the manure left from the cattle, especially if the season has been wet, and the ground tender. Two years' care will sometimes scarcely recover the land to a good and even turf, after having been much trodden or *poached*.

But with respect to agreements between landlord and tenants, it has been suggested by some, that for small farms, leases are less necessary; but a large one cannot well be let without a lease. Upon a small farm, whose land is good, a man's improvements soon come round; and if the tenant or landlord disagree, either of them is easily accommodated; but upon a large farm it is quite otherwise. It would not be worth a man's while to fix himself upon a large scale for a year or two; and it would be attended with great expence and loss, to move from any great distance, with large quantities of stock, for a short time. Besides, the plans of improvements upon a large farm are more extensive; and it is longer before the money laid out in them is returned, especially upon poor land. But undoubtedly the tenant, upon either a small or a large farm, ought to have a security for his property; and there should be an agreement to allow him a proportionate recompence for every improvement by which he has raised the land in its value, as by giving it more manure than could be made from the produce of the farm. When the manure produced upon the farm is the property of the farmer, and, by the terms of his lease, he is obliged to sell it to the coming tenant at a fair valuation, he often endeavours to make more manure the last year than any other, and by that means benefits the estate; but if, on the contrary, he is not paid any thing for it, he will perhaps do every thing in his power to prevent any future improvement upon the farm, as, on some account or another, he may fancy himself

himself ill used upon leaving it. For all under-draining properly done, and for new buildings that were necessary for the farm, the tenant ought to be allowed a reward proportionate to the number of years less than twenty he may have had the use of them. He should likewise receive an allowance for quick fences, and the planting of orchards, or of aquatics and other useful trees in proper places, on producing fair bills, with receipts to them, of the expences; provided he leaves the estate without committing any wilful waste. The landlord who enters into such a covenant with his tenant, may reasonably expect to have his farm delivered back to him upon terms equally fair. If the tenant has committed any waste, he should be obliged to make good all damages. Now such mutual conditions would do away many absurd restrictions that are at present laid upon the tenant; as it would then be his interest not to injure the farm, because he must pay for all damages wantonly done; and the landlord would have no reason to check the farmer's experiments and improvements, which would be a great encouragement to both ingenuity and industry: for gentlemen's agents are very apt, from too anxious care of the estates, to restrict tenants in such a manner, that they are little better than a mill-horse, who can go over only a particular circle of ground. It has been known that an agreement was made to lay a certain quantity of lime on land, where, if the land had been the writer's, he would have given more money than the lime cost, that it might not be laid on.

And sometimes, besides many other injurious modes of culture, which the ignorance or whim of the steward obliges the farmer to follow, he is tied down to plough and sow crops of corn only four years in six, and no turnips or clover. But the restricting a man from ploughing up grass-land without leave, is certainly, it is thought, proper, till the landlord sees what his new tenant makes of the land he does plough; but if he is industrious, and tills well, the writer would suffer him to plough every inch he chose: as, on good arable land, it will certainly make in future a difference of from one pound to three pounds an acre in rent to the landlord. The nature and situation of the farm are, however, to be well considered before this is done.

Also where the duration of the term is twenty-one years, it would, it is supposed, be very proper that, three years before the lease expires, he should be restricted in the rotation of his crops, so as to leave the farm in a proper state to be profitable to the coming tenant. This would likewise give time for the tenant to fix himself elsewhere, if the landlord and he do not agree again, as well as for the landlord to make proper choice of a new tenant.

It is very common for tenants to live in a very poor way, and obtain little profit, from the want of introducing a proper system of husbandry upon their farms, as it is only this that can afford a full profit; therefore, the best methods of management his circumstances will afford should always be pursued.

There is a great variety of regulations and restrictions in regard to tenants, in respect to the times and manner of entering upon their farms, the extent and methods of breaking up and cropping the lands, the various improvements in draining, manuring, &c. the making of fences, the selling of hay and straw, the disposing of the live-stock at the end of leases, the occupying of buildings by new tenants, the felling of timber for repairs, and a vast number of other matters, many of which are owing to the particular situations and circumstances of the lands that are to be holden by the tenants.

TENANT, or Tenant, Tenens, in Law, one that holds or

possesses lands and tenements of some lord or landlord, by any kind of right, either in fee, for life, years, or at will.

The term *tenant* is used with divers additions. Thus, *tenant in dower*, is she that possesses lands by virtue of her dower.

Tenant per Statute-Merchant, he that holds lands forfeited to him by virtue of a statute. See *STATUTE-MERCHANT*.

Tenant in Frank-Marriage, is he that holds lands or tenements by virtue of a gift of them, made to him upon marriage, between him and his wife. See *FRANK-MARRIAGE*.

Tenant by Courtesy holds for his life, by reason of a child begotten by him of his wife, being an inheritrix, and born alive. See *COURTESY*.

Tenant by Elegit holds by virtue of the writ called an *elegit*.

Tenant in Mortgage holds by means of a mortgage.

Tenant by Verge, in ancient demesne, is he who is admitted by the rod in court to lands in ancient demesne. See *VERGE*.

Tenant by Copy of Court-Roll, is one admitted tenant of any lands, &c. within a manor, which, time out of mind, have been demised according to the custom of the manor. See *COPYHOLD*.

Tenant Paravail. See *PARAVAIL*.

Tenant by Charter is he that holdeth by feoffment in writing, or other deed. See *CHARTER*, and *FREHOLD*.

Tenant in Capite, or *Chief*, holdeth of the king in right of his crown. See *CAPITE*.

Tenant of the King is he that holdeth of the person of the king.

TENANTS, Joint, those who have equal right in lands or tenements, by virtue of one title. See *JOINT TENANTS*.

TENANTS in Common, those who have equal right, but hold by divers titles.

TENANT, Particular, he that holds only for his term.

TENANT, Sole, is he who has no other joined with him.

TENANT by Execution, is he who holds by virtue of an execution upon any statute, recognizance, &c.

TENANTS, Customary. See *CUSTOMARY*.

TENANT, Terre. See *TERRE-TENANT*.

TENANT, Very. See *VERY*.

Anciently, there were also *tenant by knight-service*, *tenant in burgage*, *tenant in socage*, *tenant in frank-fee*, *tenant in villenage*. And there are still *tenant in fee-simple*, *tenant in fee-tail*, *tenant upon sufferance*, &c.

TENANT in Tail after Possibility of Issue extinct. See *TAIL*.

TENANT to the Praecept, in *Law*, is he against whom the writ of praecept is to be brought in suing out a recovery.

TENANT, or Tenan, in *Heraldry*, is used for something that sustains, or holds up, the shield, or armoury; and is generally synonymous with the word *supporter*.

The difference which some authors make between the two is, that tenants are single, and supporters double, one placed on each side of the shield. But the proper distinction seems to consist in this, that tenants are human figures, and supporters figures of beasts.

There are various forms of tenants, as well as of supporters, *viz.* angels, maids, religious, savages, Moors, &c.

The first tenants, F. Menefrier observes, were trunks, or branches of trees; to which the escutcheons were fastened by straps and buckles. Afterwards the knights were represented as holding their own escutcheons, which were either hung to their neck, or else they leaned on them.

The origin of tenants and supporters is, by many, referred to the ancient tournaments, in which the cavaliers had their arms borne by servants disguised like savages, Moors, fabulous deities, bears, lions, &c. See *SUPPORTER*.

TENA-

TENARIUM, in *Ancient Geography*. See TENARIUM. TENARUS, or TENARUS, a mountain of the Peloponnesus, in Laconia.

TENASSERIM, in *Geography*. See SIAM.

TENATARI, in *Ancient Geography*, a people who inhabited that part of Germany which corresponds to the present bishopric of Munster.

TENBURY, in *Geography*, a market-town in the upper division of the hundred of Doddington, and county of Worcester, England, is situated on the western border of the county, separated from Shropshire by the river Teme, at the distance of 21 miles N.W. by W. from Worcester, and 134 miles in the same bearing from London. The manor of Tenbury, at, or soon after the Conquest, was held by Robert Fitz-Richard, who was lord of Richard's castle; his heir assumed the name of Say, in consequence of a marriage with the heiress of that family: the property past, by a succession of heiresses, through various families, to the Cornwalls, whose descendants are still the lords of it. The town is not very extensive, and standing low, is often subject to floods from the rapid river Teme. A remarkable instance occurred Nov. 17, 1770, when a great part of the church, with its organ and monuments, were destroyed. The parish of Tenbury is three miles and a half in length, by three and a quarter in breadth; and in the year 1811 contained 308 houses, and 1562 inhabitants. In the chancel of the church is a curious monument, representing a child in armour, laid in a cross-legged position. Gough, in his *Sepulchral Monuments*, mentions this figure, and attributes it to the son of "John Sturmy, the crusader, who followed his father to the holy wars when under age."

Over the river, at the north end of the town, is a handsome stone bridge of six arches. A market is held here on Tuesdays, and there are three annual fairs. Great quantities of hops and apples are cultivated in the vicinity of the town, and consequently much cyder is made here. The Leominster canal, coming near the town, affords ready communication for goods, cyder, &c. to distant places.

About one mile and a half S.E. of Tenbury is Suttonpark, in the chapel of which are some old monuments of the Arundel family. Near this place is Kyre-Wyre, distinguished for its "tall and mighty oaks," and for a neat mansion belonging to the Pytts family.—*Nash's History, &c. of Worcestershire*, 2 vols. folio. *Beauties of England and Wales; Worcestershire*.

TENBY, a market and borough town in the hundred of Narbeth, and county of Pembroke, South Wales, is situated on the shore of Caermarthen bay, 10 miles E. from Pembroke, and 250 miles W. from London. It occupies a rocky promontory of considerable elevation, stretching over the sands in a southerly direction, and at high water is nearly inclosed by the sea. Here is a small but commodious harbour, skirted on the land-side by a bold amphitheatre of rocks and houses. Leland says, "Tinbigh town stonidith on a main rokke, but not veri hi, and the Severn se fo gulfeth in about hit, that at the ful se almost the thirde part of the town is inclosed with water. The toune is strongeli waullid and welle gatid, everi gate having his portocolis ex folido ferro. But that gate that ledith to Cairmarden ward is most femelieit, as circulid without with an embatelid but open roid towr, after the fascion of the east gate of Pembroke. Without this gate is a preti suburbe. In the middes of the town is a faire parochie chirch. The toun itself lakkith fresch water, wherfore utuntur importata." And again, "Ther is a sinus and a peere made for shyppes. The towné is very welthe by marchaundyce; but yt is not very bygge, having but one parochie chyrehe. One thing is

to be marveled at. There is no welle yn the towne, as yt is faide, wherby they be forced to fech theyr water at S. John's without the towne." The wall, which once surrounded the town, is yet in some places nearly entire. The principal improvement of these walls is ascribed to queen Elizabeth, in whose time Tenby was a flourishing place. The streets are now in general good, though, on account of the nature of the ground, in some instances inconveniently narrow and steep. They contain a large proportion of very respectable houses, occupied by substantial tradesmen and merchants, or by persons of independent fortunes. The want of water was an inconvenience under which the town long laboured: but by the recommendation and exertions of sir William Paxton, the town is now furnished, at a trifling charge, with an exhaustless supply of this necessary article. Tenby is one of the contributory boroughs joined with Pembroke in the return of a representative to parliament. The corporation consists of a mayor, aldermen, and common-councilmen, a chamberlain, town-clerk, two sheriffs or bailiffs, two sergeants at mace, and twelve constables. The town is divided into two districts, which are denominated the In-liberties, and the Out-liberties. The former division is subject to the jurisdiction of the magistrates of the borough; the latter to that of the county magistrates. The present extent of the town is not considerable, the number of houses being estimated, in the year 1811, at 265, and the population at 1176. It is apparent, however, from the number of ruined buildings and foundations to be seen in the outskirts, that formerly it must have spread over a larger space than it now occupies, and contained a much more numerous population. Two weekly markets are held on Wednesday and Saturday, and five fairs annually. Tenby seems to have derived its earliest importance from its fisheries. But when the country fell under the power of the Anglo-Norman invaders, and this district became inhabited by the Flemish settlers, its local advantages for commercial objects of greater consequence were seen and appreciated. The harbour was improved for the convenience of shipping, and the population of the town and its vicinity was engaged in a woollen manufactory on an extensive scale. The commercial spirit thus awakened, procured for the inhabitants numerous privileges and charters from their lords, and from successive monarchs. The importance of Tenby, however, has sunk far below its former rank: its manufactories have disappeared, and its chief trade at present is created by the coal raised in its neighbourhood, which is here shipped off for other parts of the coast, and for the English markets. The consequence which the town has lost in this respect seems likely to be compensated by its rapidly advancing reputation as a bathing-place. It possesses many natural attractions for visitors; and peculiar advantages in point of convenience have been recently provided. Among these, the foremost rank must be assigned to the baths lately erected by sir William Paxton; in which all accommodations for health and pleasure are combined. The church of Tenby is situated in the middle of the town; it is a spacious edifice, comprising a nave and two side aisles: at the west end is a large square tower, surmounted by a lofty spire. The monastic establishments of Tenby were an hospital, or free chapel of St. John the Baptist, a convent of Carmelite friars, founded in 1399, and called St. Mary's college, and an hospital or lazaret-house, dedicated to St. Mary Magdalen. Here was an ancient castle, of which there are yet considerable remains, though mostly in a very dilapidated state. The only portions now standing that indicate its former strength are a bastion and square tower: the rest of the buildings exhibit the air of a splendid mansion rather than

of a military fortress. The situation of this castle was admirably formed for defence: it occupied the extreme point of the promontory, and was secured by inaccessible rocks on every side, except that facing the town, which was strengthened by bold fortifications.

On the coast at Tenby are some insulated rocks of romantic appearance, which exhibit curious excavations. Some of them are accessible on foot at low water: this is the case with the island of St. Catherine, off the Castle Point, which in one direction has been perforated quite through by the repeated action of the tides. The principal of these islands is *Caldey*, situated about two miles from the main land. It is about a mile in length, and half a mile wide, and is estimated to comprise about six hundred acres of surface, of which nearly a third is in cultivation. Here was a priory, founded, as is supposed, by Robert, the son of Martin de Turribus. The tower of the priory church, surmounted by a stone spire, is yet standing, and many of the conventual buildings have been converted into offices, and attached to a handsome modern edifice.

Near the coast, to the eastward of Tenby, are several respectable gentlemen's residences, some of them of ancient date. Among these are Cilgetty, formerly inhabited by the Canon family; Hen-Gastell, (the old castle,) the property of Thomas Stokes, esq.; Merrixton, the seat of Charles Swan, esq.; Bonville Court, an ancient mansion of the Bonvilles; and Eare Wear, now called Amroth Castle, the residence of captain Ackland; and on the road from Narbeth is Begely Hall, the seat of James Child, esq.—*Beauties of England and Wales*, vol. xviii. Pembrokehire, by T. Rees. *Historical Tour through Pembrokehire*, 4to. 1810, by R. Fenton, esq. *Account of Tenby*, illustrated with etchings, 4to. 1812, by Charles Norris, esq.

TENCÉ, a town of France, in the department of the Upper Loire; 12 miles S.E. of Monistrol.

TENCH, in *Ichthyology*, the English name of the *tinca* of the modern authors, the *fullo* and *gnapheus* of the ancients.

It is, according to the Artedian and Linnæan system, a species of the cyprinus, and is distinguished by Artedi by the name of the blackish, mucous, or slimy cyprinus (which see), with the end of the tail even. See *Tench* FISHING.

TENCH'S *Island*, in *Geography*, an island in the Pacific ocean, so called by Lieut. Ball, commander of the Supply, returning from Norfolk island to England in the year 1790. The island cannot be more than two miles in circumference: it is low, but entirely covered with trees, many of which are the cocoa-nut; there were likewise others of a large size. These trees reached to the margin of a very fine sandy beach, which entirely surrounds the island. A great number of canoes were lying on the beach; and, it is supposed, there cannot be less than a thousand inhabitants on the island. The natives who were in the canoes were stout and healthy-looking men; their skin was perfectly smooth, and free from any disorder: they were quite naked, and of a copper colour; their hair resembled that of the New Hollanders. Some of their beards reached as low as the navel, and there was an appearance of much art being used in forming them into long ringlets: so that it should seem as if the prevailing fashion on this island was that of keeping the beard well combed, curled, and oiled. Two or three of the men had something like a head or bone suspended to a string, which was fastened round the neck. S. lat. 1° 39'. E. long. 150° 31'.

TENCOA, a town of Mexico, in the province of Honduras; 110 miles W. of Comayagua. N. lat. 14° 48'. W. long. 90° 22'.

TENCZA, a town of Austrian Poland; 13 miles W. of Cracow.

TEND, in our *Old Writers*, seems to signify as much as tender, or offer; as to tend or traverse an avement, &c.

TENDA, in *Geography*, a town of Africa, or rather several towns close together, the capital of a country of the same name, on the right bank of the Gambia, situated to the south-west of Bondou, and south-east of Woolly. N. lat. 13° 2'. W. long. 11° 55'.—Also, a town of France, in the department of the Maritime Alps; late capital of a county to which it gave name, annexed to Piedmont, situated at the union of the Roia and Brogna. It has only one parish church, which is a beautiful structure, a castle-walled round and flanked with towers, on a rock, which commands the environs of the town. In the 16th century, it came to the duke of Savoy. The soil is not fertile, being on all sides surrounded by the Alps; it yields, however, good pasturage and timber; the rivers also furnish the inhabitants with excellent trout; 22 miles N.E. of Nice.

TENDE, *Col de*, the most remarkable passage through the Maritime Alps. See ALPS.

TENDEBA, in *Ancient Geography*, a town of Asia Minor, in Caria.

TENDEBAR, in *Geography*, a town of Africa, in the kingdom of Kaen. N. lat. 13° 15'. W. long. 15° 57'.

TENDER, in a *legal sense*, signifies as much as to offer, or endeavour, the performance of any thing, in order to save the penalty, or forfeiture, incurred by non-performance.

Thus, to tender rent, is to offer it at the time and place when and where it ought to have been paid; which will save the condition of that time, though the landlord refuse to accept it.

TENDER, in *Sea Language*, is a vessel attending on some other larger and more considerable one. It is employed in the king's service on various occasions; as to receive volunteers and impressed men, and to convey them to a distant place; to attend on ships of war or squadrons; and to carry intelligence or orders from one place to another, &c.

TENDER *Plants*, in *Gardening and Agriculture*, all such as are too delicate and tender in their nature and habits to stand, or be raised, grown, or produced in the climate of this country, without artificial protection or assistance, until they have been sufficiently inured to, and hardened, and habituated against the effects of it. It has indeed been observed by sir Joseph Banks, in a paper containing some hints concerning the proper mode of inuring plants of this kind to this climate, inserted in the first volume of the "Transactions of the Horticultural Society" of London, that, respectable and useful as every branch of the horticultural art certainly is, no one is more interesting to the public, or more likely to prove advantageous to those who may be so fortunate as to succeed in it, than that of inuring plants, natives of warmer climates, to bear, without covering, the ungenial springs, the chilly summers, and the rigorous winters, by which, especially for some years past, we have been perpetually visited. Many attempts have, it is said, been made in this line, and several valuable shrubs, that used to be kept in our stoves, are now to be seen in the open gardens; there is, however, some reason, it is thought, to believe, that every one of these was originally the native of a cold climate, though introduced to us through the medium of a warm one; as the gold-tree, *acubia japonica*, the montan, *pæonia frutescens*, and several others, have been in our times.

In the case of annuals, however, it is thought probable that much has been done by our ancestors, and something by the present generation; but it must be remembered, it is said, that all that is required in the case of an annual, is to enable it to ripen its fruit in a comparatively cold summer, after which, we know that the hardest frost has no power to injure

injure the seed, though exposed in the open air to its severest influence; but a perennial has to encounter frosts with its buds and annual shoots, that have sometimes been so severe with us, as to rend asunder the trunks of our indigenous forest-trees, as stated by Miller.

It is suggested as probable, that wheat, our principal food corn at present, did not bring its seed to perfection in this climate, until hardened to it by repeated sowings. A few years ago, some spring-wheat from Guzerat was, it is said, sown with barley in a small cultivated field: it rose, ear'd, and blossomed, with a healthy appearance, but many ears were, when ripe, wholly without corn, and few brought more than three or four grains to perfection.

In the year 1791, some seeds of *zizania aquatica* were, it is said, procured from Canada, and sown in a pond at Spring-Grove, near Hounslow; they grew, and produced strong plants, which ripened their seeds; and those seeds vegetated in the succeeding spring, but the plants they produced were weak, slender, not half so tall as those of the first generation, and grew in the shallowest water only; but the seeds of these plants produced others the next year sensibly stronger than their parents of the second year. In this manner the plants proceeded, springing up every year from the seeds of the preceding one, every year becoming visibly stronger and larger, and rising from deeper parts of the pond, until the year 1804, when several of the plants were, it is said, six feet in height, and the whole pond was in every part covered with them, as thick as wheat grows on a well-managed field.

Here, it is thought, we have an experiment which proves that an annual plant, scarcely able to endure the ungenial summer of this country, has become, in fourteen generations, as strong and as vigorous as our indigenous plants are, and as perfect in all its parts as in its native climate and situation.

It is suggested too in the above paper, that the settlement lately made at New Holland gives a large scope for experiments of this kind: many plants have been brought from thence which endure our climate with very little protection, and some of these arrive at puberty at an early period: we have already three, it is said, from the south point of Van Diemen's island, where the climate cannot be wholly without frost; *mimosa verticillata*, *encalyptus hirsuta* and *obliqua*.

In contributing still further to the elucidation and accomplishment of this new, very useful, and important object of the above arts, the account which has been given by Dr. Maccullock, of some delicate plants which are cultivated in the open air in the island of Guernsey, with the hints on the means of naturalizing tender exotics, inserted in the first volume of the "Memoirs of the Caledonian Horticultural Society," may also be found highly useful and interesting.

It is certain, it is conceived, that neither the thermometric state of a given country, nor any meteorological condition which we have yet been able to observe, is competent to explain the peculiar affection of plants for particular regions of the earth. The observations of M. Ramond, in the "Annales du Muséum," which have been translated by Mr. Salisbury, shew this, it is said, in a striking point of view. From these we see the persevering regularity with which certain plants affect peculiar elevations, apparently unconnected with the nature of the soil, but bearing a relation alone to particular states of the atmosphere, which we have no means of appreciating. Similar facts are familiar to botanists in our own country, in the very limited zones of elevation affected by our alpine plants.

It is stated farther, that an economical object which depends on this property of plants remains yet to be noticed. This, which is still more in our power, is probably of more consequence than either of those mentioned above; what is meant is the perfect naturalization of the vine. It is well known, that from many of the ordinary varieties cultivated in this country, we can always insure a crop of grapes, but not always a crop of ripe ones. From two or three of these, the chance of ripening out of doors is considerable; from many others, it is hopeless. It is not improbable, that by successive sowings of seeds, other varieties might be produced, still more certain of ripening than those which succeed best with us, *viz.* the miller and the sweetwater. We should thus acquire possession of an article of cultivation of great importance, by which a useful addition would be made to the agricultural proceeds of land in particular situations, and by which we should be enabled to fabricate wines of a quality sufficiently good to compete with those of foreign growth.

A still more important object is, it is thought, the perfect naturalization of the potatoe, an effect as yet but very partially obtained, notwithstanding the length of time during which this valuable root has been a subject of cultivation. It is certain that this imperfect naturalization has been the result of the common practice of propagating by the tubers, to the almost total neglect of the seeds. It is true that seeds have been occasionally sown, and new varieties thus produced; but the experiment has stopped in the first stage, having been always undertaken for the mere purpose of producing these varieties, without any regard to that much more important object, the production of a plant sufficiently hardy to bear at least the first frosts of winter. In the southern parts of our island, it is not a desideratum of much importance, it is said, as the tubers are in general fully formed before the plant is killed by the frost; but in the northern parts it is an object of great consequence, the plant being frequently killed long before the roots have attained maturity. In the Highlands of Scotland, in particular, where a frost will frequently occur early in September, the crop is often prematurely destroyed, and the uses of this vegetable are in consequence materially limited. It is plain, that it would be necessary to sow the seeds of successive generations many times before the requisite degree of hardiness could be expected, and that the process would demand both patience and time. Yet if it should require more of these than we can expect from the ordinary cultivator, it is an experiment which we may at least recommend to those public bodies, which so laudably exert themselves in ameliorating the agriculture and horticulture of this country. The difficulty of procuring seeds from seedling plants, could doubtless, it is thought, be obviated, in some measure, by depriving the young plant of its tubers, and thus compelling it to direct its energies to the other and more common mode of propagation, with which nature has provided all plants.

The writer cannot, however, conclude the suggestions in respect to this object or speculation, without noticing a formidable objection which stands in the way of our attempts to naturalize particular plants. In every case where the useful varieties have been the result of cultivation in a warmer climate from a base and useless parent, it is to be feared, it is said, that the process followed in naturalization, would again throw the plant back to its original state. This objection applies, it is supposed, chiefly to those fruits, such as the peach, the apple, and the grape, which, in their present cultivated state, are almost entirely the produce of art. For this reason, it is not improbable, that all attempts to natural-

ize the grape to a cold climate may fail; yet the trial deserves, it is said, to be made. The case does not apply equally to the potatoe. The original plant appears to be valuable, independent of any artificial character, and would consequently admit of a change, tending even to some degree of deterioration, before it was materially injured in its properties.

TENDERING, a name given to the soft tops of deer's horns, when they begin to shoot forth.

TENDING, in *Sea Language*, denotes the movement by which a ship turns or swings round her anchor in a tide-way at the beginning of the flood or ebb. Thus, if the flood sets northerly, it is evident that the ship, unless when moored head and stern, will fall into the line of the current, turning her head to the southward, and *vice versa*. This transition from one situation to the other is called tending or swinging. Falconer.

TENDINOSUM CENTRUM. See **CENTRUM**.

TENDON, **TENDO**, in *Anatomy*, the hard, inflexible cords, by means of which muscular fibres are attached to bones. See **MUSCLE**, after the description of the muscular system of animal life; and **FIBROUS SYSTEM**.

TENDO Achillis, the powerful tendon belonging to the muscles of the calf of the leg, placed just above the heel; so named in allusion to the fable, in which Thetis is said to have held her son, Achilles, by this part, when she dipped him in the Styx. See **GASTROCNEMIUS**.

TENDON of Achilles, Ruptured. When the tendo Achillis is unfortunately cut, or ruptured, as it may be in consequence of a violent exertion, or spasm of the muscles, of which it is a continuation, the use of the leg is immediately lost; and unless the part be afterwards successfully united, the patient must remain a cripple for life.

The ancient surgeons seem not to have been well acquainted with the rupture of the tendo Achillis, which they probably might mistake for a sprain, or some other complaint. In cases in which this part had been cut, they recommended approximating the separated portions, and maintaining them in contact by means of a future.

When the ruptured tendo Achillis was afterwards better understood, the plan which we have just now mentioned was still continued, the integuments being divided for the purpose of bringing the tendon into view. But that such a painful mode is altogether useless and wrong, it is scarcely necessary for us at the present day to observe.

The superficial situation of the tendo Achillis always makes the nature of the accident easy of discovery, and it is only when there is a considerable degree of swelling (which is very rare), that the case can be at all difficult to understand. When the tendon has been cut through, which is not an ordinary thing, the division of the skin brings the ends of the sinew into view. When the tendon has been ruptured, the patient hears a sound, like that of the smack of a whip, at the moment of the occurrence. In whatsoever way the part has been divided, there is a sudden incapacity, or, at least, an extreme difficulty of standing and walking. Hence the patient falls down, and cannot get up again. Besides these symptoms, there is a very palpable depression between the ends of the tendon, which depression is increased when the foot is bent, and diminished, or even quite removed, when the foot is extended. The patient can spontaneously bend his foot, none of the flexor muscles being interested. The power of extending the foot is still possible, as the peronei muscles, the tibialis posticus, and long flexors, remain perfect, and may perform this motion. *Œuvres Chirurgicales de Desault par Bichat, tom. i.*

The indications are to bring the ends of the divided part

together, and to keep them so, until they have become firmly united. The first object is easily fulfilled by putting the foot in a state of complete extension; the second, namely, that of keeping the ends of the tendon in contact, is more difficult.

In order to have a right comprehension of the indications, we should consider what keeps the ends of the tendon from being in contact. The flexion of the foot has this effect on the lower portion; the contraction of the gastrocnemius and soleus on the upper one. The indications then are to put the foot in an unalterable state of extension, and to counteract the action of the above muscles.

The action of the muscles may be opposed: 1. By keeping these powers in a continual state of relaxation. For this purpose, the leg must be kept half bent upon the thigh. 2. By applying methodical pressure to the muscles; methodical, because it is to operate on the fleshy portion of the muscles, and not on the tendon, the ends of which being depressed by it, would be separated from each other, and, instead of growing together, would unite to the adjacent parts. The pressure should also operate so as to prevent the ends of the tendon from inclining either to the right or left.

This kind of pressure, which the bandage ought to make, seems to have escaped the attention of all authors. Who cannot see, however, that the action of the muscles being by this means resisted, the upper end of the tendon will not have such a tendency to be drawn upward, and separated from the lower one? *Œuvres Chirurgicales de Desault par Bichat, tom. i.*

The famous Petit seems entitled to the honour of having first devised the plan of treating the ruptured, or divided tendo Achillis, by keeping the leg and foot in a particular posture, with the aid of an apparatus. Seeing that the extension of the foot brought the ends of the tendon into contact, it occurred to him that such extension should be maintained during the whole of the treatment, in order to bring about a permanent union. This happy idea, the simplicity of which should have rendered it obvious to all practitioners, once having originated, became the common basis, on which have been founded all the numerous methods of cure, which have been since recommended. *Desault par Bichat.*

The celebrated Dr. Alexander Monro, professor of anatomy at Edinburgh, happened to rupture his tendo Achillis. When the accident took place, he heard a loud crack, as if he had suddenly broke a nut with his heel, and he experienced a sensation, as if the heel of his shoe had made a hole in the floor. This sensation, he says, has also been observed by others, though some have complained of a smart stroke, like what would be produced by a stone or cane. Immediately suspecting what had happened, the doctor extended his left foot, in which the occurrence had taken place, as strongly as he could with his right hand, while with the left he pressed the muscles of the calf downward, so as to bring the ends of the broken tendon as near together as possible. In this position he sat, until two surgeons came to his assistance. They applied compresses, and a bent board to the upper part of the foot, and fore part of the leg, both which they kept, as nearly as possible, in a straight line, by a tight bandage, made with a long roller. But as this mode of dressing soon became very uneasy, it was changed for the following one. A foot-sock or slipper was made of double quilted ticking, from the heel of which a belt or strap projected, of sufficient length to come up over the calf of the leg. A strong piece of the same materials was prepared, of sufficient breadth to surround the calf, and this was fastened with lacings. On the back part of this

was a buckle, through which the strap of the foot-sock was passed, so that the foot could be extended, and the calf brought down at pleasure. The leg and foot were wrapt up in soft flannel, fumigated with benzoin, and the bandage was kept on day and night, the belt being made tighter when the doctor was about to go to sleep, and loosened when he was awake, and on his guard. For a fortnight he did not move his foot and leg at all, but was conveyed in a chair on castors from one part of the room to another. After this he began to move the ankle-joint, but in such a gentle manner, as not to give any pain. The degree of motion was gradually increased, as the tendon became capable of bearing it, care being taken to stop, when the motion began to create uneasiness. The affected limb was moved in this way, for half an hour at a time. In a few days, the hollow between the separated ends of the tendon became imperceptible, though the part continued soft much longer. It became, however, gradually thicker and harder, until a knot was at last formed in it, apparently of a cartilaginous nature. Though this was at first as large as a middling plum, and gradually became softer and smaller, yet it did not disappear entirely. Having occasion to go out six weeks after the accident, the doctor put on a pair of shoes, with heels two inches high, and contrived a steel machine to keep his foot in the proper position. This machine, however, he afterwards changed for another, made of the same materials as the former. It was not till five months after the accident, that he thought proper to lay aside all assistance, and to put the strength of the tendon to a trial. See *Monro's Works*, p. 661.

It seems unnecessary to enumerate the various plans devised since the time of Petit. Suffice it to state, that both in a wound and rupture of the tendo Achillis, the ancient method of using a future, for keeping the ends of the tendon in contact, is at present quite exploded, and position of the limb is the grand agent by which the cure is now universally accomplished. The following was Default's method, which, though it was expressly designed to fulfil all the above-mentioned indications, may not after all be a more valuable practical plan, than the one adopted by Dr. Monro. After the ends of the tendon had been brought into contact, by moderate flexion of the knee, and complete extension of the foot, Default used to fill up the hollows on each side of the tendon with soft lint and compresses. The roller applied to the limb made as much pressure on these compresses as on the tendon, and hence this part could not be depressed too much against the subjacent parts. Default next took a compress, about two inches broad, and long enough to reach from the toes to the middle of the thigh, and placed it under the foot, over the back of the leg, and the lower part of the thigh. He then began to apply a few circles of a roller round the end of the foot, so as to fix the lower extremity of the longitudinal compress. After covering the whole foot with the roller, he used to make the bandage describe the figure of 8, passing it under the foot, and across the place where the tendon was ruptured, and the method was finished by encircling the limb upward with the roller, as far as the upper end of the longitudinal compress. Default par Bichat.

Certainly this plan seems to answer every object, and may be worthy of being adopted in this country. The continued pressure on the muscles of the calf, by which their action is materially resisted, is too much disregarded by the generality of English surgeons. Consult *Monro's Works* Encyclopédie Méthodique, article *Achille, tendon d'*; and *Mémoire sur la Division du Tendon d'Achille*, in *Œuvres Chi-*

rurgicales de Default par Bichat, tom. i. p. 306. Cooper's *Dict. of Practical Surgery*.

TENDONS, *Shooting of the, Subfultus tendinum*, in *Medicine*, a slight and repeated convulsive twitching of the muscles, which occurs in the latter stages of low fevers; and, as it indicates great debility, and a very morbid condition of the brain or common sensorium, it is usually reckoned among the dangerous symptoms of fever. See FEVER, and TYPHUS.

TENDON, in the *Manege*, a sort of gristle that surrounds one part of the horse's foot, and is seated between the hoof and the coffin-bone, near the coronet. When a horse has a quitter-bone, the matter that gathers between the coffin-bone and the hoof spoils the tendon, and makes it black; and the cure of such a quitter-bone consists in cutting and extirpating the tendon.

TENDREMENT, Fr. in *Music*, tenderly, equal to *cor tenerezza*, Ital. See *CON Affetto*, and *AFFETTUOSO*.

TENDRIL, in *Botany and Vegetable Physiology*. See *CIREUS*.

TENDUCCI, FERDINANDO, in *Biography*, an opera-singer in soprano, born at Sienna, whence he at first assumed the name of Senesino, or account of the celebrity of a singer of that city, in the early part of the last century; though neither his voice nor style of singing at all resembled that of the great singer and actor, Francico Bernardo detto Senesino, whose voice was a rich and full contralto, and in whose singing and acting there were more of grandeur and dignity than tenderness and expression, which characterized Tenducci's style; and whose voice was a high soprano of a clear silvery tone, which by great pains he had rendered very flexible; but he had formed himself more on Caffarelli's style than on that of Senesino.

He arrived in England, as second man, in 1758, when Potenza was principal. The first notice he obtained was in a cantabile air, set by Caffarelli for himself, in a fine style of grand pathetic, such as six years after, Manzoli's fine adagio in Ezio, "Caro mio bene addio," was composed in by Pescetti.

It was in 1759, during the reign of Cocchi's "Ciro riconosciuto," that he became a favourite of the public: for though a young performer, and only second in rank under Potenza, he had a much better voice and manner of singing than the performer to whom he gave precedence.

In 1760 he went to Scotland, and we hear no more of him till 1763, when he returned to London, and performed the principal man's part in Dr. Arne's *Artaxerxes*, of which the success was greatly owing to his talents.

At this period, Bach and Abel established a weekly subscription concert in Hanover-square, which was better patronized and longer supported than perhaps any one had ever been in this country, having continued full twenty years with uninterrupted prosperity, at which, during the chief part of the time, Tenducci was the principal singer.

In 1770 he succeeded Guadagni as first man at the great opera, performing that year with the Grassi in "Corroe," and the next year in "Semiramide riconosciuta."

In 1764 he went to Ireland, where he and Miss Brent performed together in *Artaxerxes*.

In 1765 an Italian opera was performed in Dublin, in which he and the Cremonini sung principal parts in *Mithridates*, in the principal cities of that country.

Some time after he returned to London, and was engaged at the opera, where, in 1785, he revived Gluck's *Orfeo*.

Such is the outline of his professional career in public. The events of his private life are still more varied.

He had not been long in England before he was thrown
U u 2 into

into the king's bench for debt, where he embellished that residence by his talents, and amused its inhabitants. He was, however, allowed to attend evening concerts elsewhere, attended by a *garde du corps*. But on these occasions, a Jewish lady, his patroness, carried him in her carriage to the performance, and conducted him safe back with his attendant to his limited residence; where, during a part of the time, he had the honour of Dr. Smollet for his neighbour.

In Scotland he sung at the Edinburgh concerts, and gave lessons in fingering; by which occupation he improved his own talents so much, that he returned to London a much better singer than when he left it. So true is the observation of Aristotle, that no art or science is well learned but by *teaching*, when it is necessary to give reasons for what in private practice is done mechanically.

In Ireland he married a lady of considerable fortune, who was enchanted by his talents.

In Italy, whither he carried this lady, he was unmarried, the laws of that country forbidding conjugal union to castrati. And on his application to the pope for a dispensation, it was refused; though the petitioner said that his reason for marrying was, the operation in his youth not having been completely performed: "why then," says his holiness, "let it be done more effectually;" and he was obliged to separate himself from his tender spouse, and the to console herself with a more efficient husband.

When he quitted the stage, he employed his whole time in teaching to sing; had many scholars, and a good method of instruction; giving to his pupils, in English, a set of axioms or rules of study and practice translated from the Italian, drawn up, as he said, by himself; but which, after his decease, were found in the *Solfeggi* of Aprile.

Notwithstanding the great number of his scholars, his income was insufficient to keep him out of debt, or even the king's bench, without the ingenious expedient of becoming a bankrupt, by which he defrauded all his creditors, and died insolvent, being, as has been reported, buried at the expence of his countrymen, who made a collection for that purpose at the Orange coffee-house. But from better authority, we have been informed that he died at Genoa.

Tenducci had much professional merit; but as to probity, honour, and ideas of right and wrong, they never seem to have extended further than convenience and personal safety.

TENDUNCULO, in *Geography*, a river of Africa, which runs into the Indian sea, S. lat. 19° 20'.

TENEA, in *Ancient Geography*, a town of Corinth, on the frontiers of Sicyonia, S. of Epicria. It pretended to derive its foundation from the Trojans made prisoners in the isle of Tenedos, and brought into this country by Agamemnon. Apollo was much honoured here.

TENEBRÆ, DARKNESS, in the *Romish Church*, a service performed on the Wednesday, Thursday, and Friday before Easter, in commemoration of the agony of our Saviour in the garden; and the darkness that overspread the earth at the time of his crucifixion.

TENEBRIO, in *Entomology*, a genus of the Coleoptera order of insects, the generic character of which is, that the antennæ are moniliform, with the last joint rounded; the thorax plano-convex, margined; the head exerted, and wing-sheaths stiffish.

In the insects of this genus the body is oblong-oval, and in most species somewhat pointed at the extremity. Several species are also destitute of wings. This is a numerous genus, and is divided by Fabricius and others into several distinct genera, under the appellations of *Pimelia*, *Bleps*,

Aturmus, &c. In Gmelin's edition of Linnæus it comprehends 63 species. The European species are denoted by an asterisk.

A. *Six filiform Feelers; anterior Legs formed for digging, palmate-dentated; including the Scaritæ of Fabricius and Pallas.*

Species.

COMPLANATUS. Black, with a subquadrate thorax, and smooth shells or wing-sheaths; of a large size. Found at Cayenne.

MARGINATUS. Black, with a subquadrate thorax; fulcated shells; blue margin. Found at Cayenne.

GIGANTEUS. Black, with fulcated mandibles, and smooth shells. Found in Africa; nearly allied to the next species, but thrice as large.

SUBTERRANEUS. Black, with the fore-part of the head fulcated, and striated shells.

CYANEUS. Blue, very smooth; antennæ and feet black. Found in New Holland.

* FOSSOR. Pitchy. Found in sand-hills, which it perforates.

* CURSOR. Brown; oblong thorax; five angles denticulated. Found as the former.

ARABES. Black; ferrated thorax; antennæ and feet testaceous. Found in the East.

MINUTUS. Black; thorax margined; antennæ clavated, and feet pitchy. Found in Sweden; and twice as large in Saxony.

COLLARIIS. Black, with shells punctate-striated, and head brown; antennæ and feet pitchy; the anterior spinous. Found at Berlin.

BUCEPHALUS. Wholly brown, punctated; eyes black. Found in India.

B. *With unequal filiform Feelers.*

ATRATUS. Wholly black, smooth. Found in Egypt.

C. *With four Feelers; the anterior subclavate; the posterior filiform; the Tenebriones of Fabricius, and Mylarides of Pallas.*

LAMINATUS. Black; thorax subquadrate, smooth; shells fulcated; anterior legs incurvated at the apex, and ferruginous lamina acute. Found in India; the largest of the genus.

GIGAS. Black; shell striated; thorax smooth. Found in Surinam.

PUNCTATULUS. Black; thorax quadrate; margin subdenticulate; shells striate-punctated. Found in India; of a large size.

SERRATUS. Black, smooth; shells striated; posterior legs striated. Found in Sierra Leone.

* MOLITOR. Wholly black; thighs anterior thicker:—an insect often seen in houses, one of the smaller kinds, proceeding from a larva commonly known by the name of meal-worm, from its being so frequently found in flour, &c.; it is of a yellowish-white colour, about an inch long, slender-bodied, and of a highly polished surface, and is considered as the favourite food of the nightingale, in its captive state, and said to remain two years before it changes into a chrysalis.

LURIDUS. Black, with brown feet. Found in Brasil.

CHALYBEUS. Violet, with feet and antennæ pitchy. Found in Guinea.

MAURITANICUS. Black, beneath pitchy; margins of the

the thorax anterior and posterior angulated. Found in Algiers.

VARIEGATUS. Oblong, with varied brown and cinereous. Found in Africa.

ABBREVIATUS. Ovate, black, with shell striated, and head tuberculated. Found in India.

CAPENSIS. Ovate, black; shell striated; anterior legs dentated-spinous. Found at the Cape of Good Hope.

CORNUTUS. The margins of the double-horned thorax crenated, and the angles projecting. Found in Smyrna.

SANGUINIPES. Black, with antennæ and feet sanguineous. Found in New Holland.

BUPRESTOIDES. Black; oval, thorax margined; the connate shells smooth. Found at the Cape of Good Hope.

DERMESTOIDES. Black; thorax oval, margined; shells striated. Found in Saxony.

CULINARIS. Ferruginous; shells striated; shield emarginated. Found in Spain and Sweden.

BARBARUS. Black, very smooth; thorax orbiculated; the shield of the head on the fore-part, with the margin elevated. Found in Mauritania.

* **ERRATICUS.** Black; the antennæ, suborbiculate thorax, and shells ferruginous; brown at the apex.

PALLENS. Paley testaceous; thorax transverse. Found of a small size at the Cape of Good Hope.

FERRUGINEUS. Ferruginous, with shells striated testaceous. Found in Africa.

* **VILLOSUS.** Brown, cinereous-villose, shells smooth and ferruginous.

* **CARABOIDES.** Black; thorax oval, margined; shells striated.

BRUNNIPES. Black, smooth; shells striated; antennæ and feet ferruginous. Found at Dresden.

LEVIGATUS. Oblong, black, with smoothish shells. Found in Africa, of a less size than the molitor.

GIBBOSUS. Subovate; wholly brassy, shells gibbous-convex; the very fine striæ crenulated. Found in Brasil.

SPINIMANUS. Thorax margined, smooth, shells very smooth; posterior obtuse; fore-legs produced with a very strong arched spine. Found in Southern Russia.

UNCINUS. Apterous, black; thorax margined, subequal; shells striated-punctated and angulate; thighs anterior, clavated, very large, biuncinate. Found in Spain.

PICEUS. Depressed, black; beneath pitchy; shells striated. Found in Saxony.

CYLINDRICUS. Very black; thorax with elevated points; antennæ brown; the tarsi beneath yellow-haired. Found at Berlin.

MONTANUS. Wholly black; shells opaque. Found in Hungary.

TRISTIS. Black, sub-opaque, varied with excavated points. Found in Carniola.

POMONÆ. Above pitchy, beneath black; shells with five elevated striæ. Found in Carniola.

CAPREÆ. Black; points impressed on the thorax and shells testaceous. Found in Carniola and Switzerland.

FLAVUS. Yellow, with black eyes. Found in Carniola.

ÆSTIVUS. Black; feelers and feet yellow. Found in Denmark.

STRIATUS. Black; the abdomen beneath densely striated. Found in Denmark.

FESTINANS. Wholly black, smooth; thorax ferruginous.

GLOBOSUS. Black; thorax globose; two rough lines elevated. Found in Siberia.

INCURVATUS. Wholly pitchy; shells striated across the middle. As the last.

OVATUS. Ovate, blackish-brown; shells with eight striæ, smooth.

ROTUNDATUS. Black, wholly smooth: the coleoptra rotundata.

SUBVILLOSUS. Wholly ferruginous, subvillose.

GLABER. Wholly ferruginous, smooth. The four last found in France.

* **LIGNARIUS.** Thorax with two cavities; shells violet or red; antennæ and feet ferruginous.

LARDARIUS. Oblong, yellow-fulvous; eyes black; shells with punctated striæ. Found in Belgium.

* **CURVIPES.** Ovate, pitchy; shells punctated-striate; thighs crenated; the hinder beneath ciliated.

* **BICOLOR.** Ovate; shells striated; above black; the antennæ beneath and feet ferruginous.

* **ATER.** Black; antennæ ferruginous.

* **LUNATUS.** Black; depressed thorax lunated; shells striated; feet ferruginous.

* **HISPIDUS.** Black, rough; shells striated; a spot at the base on both sides red; the antennæ and legs red.

* **GLABER.** Ferruginous; head and thorax smooth, and shells black; these striated; mouth ferruginous; feet livid.

TENEBRIO *Mortifagus*, a species of the *Pinelia*, (which see,) in the Gmelinian edition of the Linnæan system, thus described by Dr. Shaw. It is a coal-black insect, measuring about an inch in length, of rather slow motion, and distinguished by the remarkably pointed appearance of the wing-sheaths, which at their extremities project a little beyond the abdomen; they are also perfectly connate or undivided, forming a complete covering to the body, and being carried over the sides to some distance beneath, and the insect is totally destitute of real or under wings. It is usually found in dark neglected places, beneath boards, in cellars, &c. and if handled, especially if crushed, diffuses a very unpleasent smell.

TENEBRIMUM, in *Ancient Geography*, a promontory of Spain, belonging to the Ibercaones. Ptol. It lay S. of the mouth of the river Iberus.

TENEDOS, in *Geography*, an island of the Grecian Archipelago, near the coast of Asia, and very near the Troade. This island has been successively celebrated by Homer and Virgil. The latter thus describes it:

“Est in conspectu Tenedos, notissima famâ
Insula, dives opum, Priami dum regna manebant;
Nunc tantum finus et statio malefida carinis.”

According to Diodorus Siculus, it had anciently been called Leucophris; but when Tenos or Tennes built a town upon it, he called it Tenedos. Bochart, however, derives its name from the Phœnician word Tin-edum, red clay, which was found here, and used for making earthen-ware. Pausanias says, that this island, which was situated within sight of the city of Troy, became miserable after the capture of that city, and was obliged to surrender to its neighbours, who had built Alexandria upon the ruins of Troy. It was one of the first conquests of the Persians, who made themselves masters of it, after having defeated the Ionians at the isle of Lada. It took part with the Athenians against the Lacedæmonians, when an admiral of the latter people ravaged it, and drew from it contributions. The Romans had possession of it, and Verres pillaged the temple, and carried away the statue of Tennes, the supposed founder of the town. Strabo represents it as 24 stadia in circumference, and places it at the distance of 11 stadia from the continent; but Pliny states this distance to be 12 miles. Olivier computes the distance to be nearly 3000 toises: and he says, that the town is at the distance of about five leagues from

from the entrance of the Hellespont. This position has always rendered Tenedos important. Vessels bound to Constantinople find shelter in the ports of this island, or safe anchorage in the roads, when the winds are contrary and the weather bad. The emperor Justinian established in this island a magazine for receiving cargoes of corn transported from Egypt, 180 feet long, 90 broad, and proportionally high. During the troubles of the Greek empire, Tenedos sustained many vicissitudes. It was for many years a place of rendezvous for pirates. Scantly peopled and ill defended, it passed betimes under the Ottoman domination. The caliph Othman seized it in the year 1302, and in the possession of it, he was enabled to subdue the other islands of the Archipelago. During the minority of Mahomet IV. the Venetians retook it after the complete defeat of the Turkish fleet in the strait by the admiral Mocenigo, in 1656: but in the following year, the admiral having been killed in a second engagement, the Venetian fleet retired, and this island fell again under the power of the Turks, who have preserved it without interruption till the present day. The harbour is small, and can only receive merchant vessels: it is formed by a jetty even with the water's edge, and a tongue of land, on which is constructed the citadel that defends the entrance, and can at most secure it against being surpris'd by a privateer. The town is built in form of a semicircle, in a valley, and on the declivity of two hills: its population is from 5000 to 6000 souls, judging from its extent, and from the number of persons who pay the karatch. Its inhabitants, who are Turks and Greeks in equal numbers, are almost all occupied in the culture of the lands, few of them being mariners. The island is under the administration of a waiwode or governor, an aga commandant of the citadel, and a cadî or judge. The defenders of the town are 200 or 300 janizaries. The town is commanded by a pyramidal mountain of small elevation, that seems to have been formed by the action of a volcano, the traces of which are discoverable. In the environs is found a granite remarkable for pieces, of various sizes, of felspar crystallized. On the right of the mountain, in passing from the town towards the W., is a sandy plain, far from fertile, and almost entirely covered with vines. The hills, in general, are naked, dry, and little susceptible of culture. Those on the south of the town are calcareous; and the rock is more or less chalky and loaded with sea-shells.

Tenedos produces little corn, fruit, or herbage. The vine is the only article of wealth of this country, and its culture the principal occupation of the inhabitants. Muscadell wine is made in considerable quantities. From Tenedos are annually exported upwards of 600,000 okes of wine, producing to the farmer more than 30,000 piastres. This wine passes to Constantinople, Smyrna, and Russia. This island also exports a small quantity of brandy. The climate of Tenedos is more temperate than that of the Dardanelles: it seldom freezes here, and the summer heats are moderated by the N.N.E. wind, which blows regularly during the day. The houses have terraces of flat roofs. The Greek inhabitants are less gay than those of the other island: in the streets they are silent and melancholy, avoiding through fear the attention of the Turks; but when they can indulge themselves in mirth without danger, they surrender themselves to a sort of extravagant joy and delirium. The coast of Troy is frequently the theatre of their orgies and the field of their pleasures: thither they repair on the occasion of a wedding or of a festival, and there, under the shade of a plane-tree or oak, they pass the whole day in dancing, singing, eating and drinking. The females, however, are kept within the bounds of decorum, and might be compared, from their

features and their shape, to the most beautiful models which antiquity has transmitted to us. N. lat. 39° 53'. E. long. 26°. Sonnini. Olivier.

TENELLA, *τενελλα*, in *Ancient Music*. As some conquerors at the Olympic games were not so fortunate as to have poets for their friends, or so rich as to be able to purchase odes on their particular victories, which were rated very high by bards of the first class; in honour of such, the old hymn to Hercules, of Archilochus, was sung by the friends of the conquerors only, if they could not afford to engage a band of professed musicians. The scholiast on Pindar's ninth Olympic tells us, that to supply the want of a citharædist, Archilochus framed a word in imitation of the sound of a cithara, which word (*Tenella*, *τενελλα*), when there happened to be no musician present, the leader of the chorus chanted forth, and was answered by the rest of the chorus, in the words of the hymn, *Ω Καλλιστοι, χαυρε, Ο glorious Viator, hail!* at every comma, or pause of which, this burden was again repeated.

TENEMBER, in *Geography*; an island in the East Indian sea, 12 miles long and 3 broad. S. lat. 6° 50'. E. long. 132° 45'.

TENEMENT, TENANCY, in *Law*, a house or lands, depending on a manor, or lordship; or a fee, or farm held of a superior lord, and which he may recall, when the term or condition is expired.

TENEMENT, *Frank*, is any lands, house, office, or the like, in which a man has estate for life, or in fee.

TENEMENT, *Base*, is where a man holds lands, &c. at the will of the lord.

Yet Kitchen, Briton, &c. make frank tenement and base tenement opposites; on which footing, frank tenement should be where the tenant is at liberty to quit it when he pleases.

TENEMENTARY LANDS, among our ancestors, were the outlands of manors, which the Saxon thanes, or nobles, let out to tenants under arbitrary rents and services.

TENEMENTIS LEGATIS, in *Law*, a writ which lies in London, and other places, where the custom is to devise tenements by last will as well as personal goods and chattels, for the hearing of any cause relating to them.

TENEN, or KNIN, in *Geography*, a town of Dalmatia, situated on the borders of Bosnia, and the see of a bishop; 48 miles S. of Bihaes.

TENENDUM, in *Law*, is a clause in a deed, in which the tenure of the land is created and limited. The office of a tenendum is to limit and appoint the tenure to the land which is held, and how, and of whom it is held. The tenendum seems now to be incorporated with the *habendum*, for we say, to have and to hold, in which clause the estate is limited, &c.

TENENTES NATIVI. See NATIVI.

TENENTIBUS in *Assisa non Onerandis*, in *Law*, a writ which lies for him to whom a disseisor has made over land, of which he disseised another; requiring that he be not disturbed in assize, for the damages awarded, if the disseisor have wherewithal to satisfy them.

TENEREZZA, tenderness, feeling, equivalent to the French term *tendrement*.

TENERIA, in *Geography*, a town of the island of Cuba; 45 miles N.W. of Villa del Principe.

TENERIFFE, one of the Canary islands, the second in dignity, but the first probably with regard to wealth and fertility. It is about 70 miles in length, and its mean breadth is about 22 miles: its surface contains 1540 square miles, having, at an average, about 45 persons to the square mile.

TENERIFFE.

mile. The number of acres is 985,600, which, upon an average, allots about 10 acres to every individual in it; the number of inhabitants being calculated to be nearly 100,000. Of these there is annually a considerable migration to the Spanish colonies in South America. The poor of Teneriffe are easily persuaded to migrate, as the proprietors of the land do not give them sufficient employment throughout the year; and they have not the resource of manufactures, except a trifling one in silk, chiefly stockings. The price of labour is under a shilling a day; and, beside corn and roots, the principal food of the common people is confined to cod-fish, caught on the neighbouring coast of Africa, or imported from North America. This island was formerly called Nivaria, which appellation it derived from the circle of snow that surrounded the peak of Tenda, now called the peak of Teneriffe; which name was given to it, as it is said, by the inhabitants of Palma island, in whose language *tener* signifies snow, and *effe* a mountain. The figure of this island is triangular, as it extends into three capes, the nearest being about 80 leagues or more from the coast of Africa. The historical celebrity of this island has been very much owing to its *Peak*, elevated to a considerable height from a base lying a little to the S.W. of its centre. Of its height we have various statements by different writers, who have ascended to its summit. Dr. Heberden, whose observations in ascending it are published in the *Phil. Transf.* vol. xlvii. makes its height above the level of the sea to be 2566 fathoms, or 15,396 English feet; and he says that this measure was confirmed by two subsequent observations by himself, and another made by Mr. Croffe, the consul. Nevertheless, chevalier de Borda, who measured the height of this mountain in August 1776, makes it to be only 1931 French toises, or 12,340 English feet. Mr. Johnstone, a merchant of Madeira, being on board ship in the offing of Orotava, took the angles made by a line from the horizon to the summit of the Peak, at two different spots, and measuring the distance between them by the log, determined the perpendicular height of the Peak to be 2023 English fathoms, being nearly the same as Chev. de Borda had calculated from a base measured upon land. From the comparative observations of Monf. de Borda's barometers, upon the Peak, and by the sea-side, the mountain's height came within two fathoms of the geometrical measurement. The Hon. Grey Bennet, who made a journey to the top of the Peak in 1810, states its height to be about 12,500 feet. M. de Lemanon and Monges, on the 26th of August 1785, ascended the Peak, and stating its elevation above the level of the sea to be near 1900 toises, made some chemical experiments, in order to compare the phenomena at that height with those which occur in our laboratories. They observe, that the crater of the Peak is a perfect solfatara or laboratory of sulphur; its diameter being about 50 toises by 40, rising with a steep and rapid ascent from W. to E. On the edges of the crater, and particularly towards the lowest part, are several apertures or vents, exhaling watery and sulphuric acid vapours, the heat of which raised the thermometer from 9° to 34°. The interior of the crater is covered with yellow, red, and white clay, and fragments of lava partly decomposed. Under these were found beautiful crystals of sulphur, forming rhomboidal octohedra, some of which were an inch thick. The steam exhaled from the apertures was pure water, not at all acid. The evaporation of liquids, and the cold thus produced, were very considerable. The action of the acids on metals, earths, and alkalis was slow, and the bubbles that escaped during the effervescence were much larger than usual. The production of vitriols afforded a singular phenomenon. That of iron instantly assumed a

fine violet colour, and that of copper precipitated with a very vivid hue. The smell and strength of liquors appeared not to have lost any thing at this elevation, and the volatile alkali, ether, and alcohol, retained the same strength. Several experiments were made with a view of ascertaining the nature of the vapours exhaled from the crater, and whether they contained inflammable air, fixed air, or marine acid. From these he concluded that no fixed air exhaled from the crater, and also that the atmospheric air resting upon it contains very little, and that the inflammable vapours and sulphuric acid gas alone are considerable, and indeed perceivable. The atmospheric electricity was considerable and positive. Many new varieties of volcanic schorls were discovered. See *La Peroufe's Voyage*, vol. ii. p. 226, &c.

Dr. Heberden gave sir Joseph Banks some salt which he collected on the top of the mountain, where it is found in large quantities, and which he supposed to be the true *natrum*, or *nitrum*, of the ancients. Although the vortex appears sharp, and of the exact resemblance of a cone, yet it is flat for the extent of an acre of ground, in the centre of which is a dreadful volcano, which frequently breaks out into flames, so violent as to shake the whole island with an incredible force. Smoke constantly issues from the mountain, near its summit, but no eruption has occurred since the year 1704, when the port of Garrachica was destroyed, and the harbour filled by the lava. The island of Teneriffe is divided in the middle by a ridge of mountains, which have been compared to the roof of a church, the Peak forming the spire or steeple in the centre. An author well acquainted with the island says, that if you divide it into twelve parts, ten of these consist of rocks, woody and inaccessible mountains and vineyards; and yet, from the small remainder of arable ground, he has seen 250,000 hanacks of wheat, besides immense quantities of rye and barley, produced. The greatest part of the island is volcanic, and all its rocks are lava. Mr. Bennet (*Transf. of the Geological Society*, vol. ii.) conceives, that formerly a very large crater, 12 miles in diameter, existed, the sides of which, under the name of *Las Foldas*, may be still traced a great way. The crater at the top of the Peak is but small, and somewhat in activity. The lavas vary in their appearance: some are composed of hornblende and feldspar, without any foreign body; these are porphyritic: some are composed of green-stone, and contain olivin, augite, and zeolites: some are basaltic; these decompose the soonest, and constitute the most fertile soil: there are also pumice in abundance, tufa ashes, and a lava resembling obsidian. Every circumstance, it is said, argued in favour of a volcanic formation, except the form of the mountains, whose irregular ridges, declivities, and ascents, appeared very different from those exhibited by volcanic mountains. In the plain beyond Laguna, on the Orotava side, the soil was not in the least volcanic, but composed of fine mould, or virgin earth; a mixture of clay, vegetable earth, and sand. Hollows, 30 feet deep, left dry by rivulets, exhibit no volcanic appearance. Immediately under the superficial soil was a layer of deep loam, next, one of tough clay, and all below was an irregular mixture of clay and sand. Elsewhere the hills consisted of indurated clay, and clay and iron, without any marks of the action of fire. In the whole island, there is no pure flint or sand-stone. Its mountains are of two sorts; one, evidently volcanic; the other, primary and composed of indurated clay, or of clay and caix of iron. In the low plains are layers of loose and soft argillaceous earth. (See Dr. Gillan's remarks in the 1st vol. of the *Embassy to China*, p. 118—120.) Although the people live on scanty and coarse fare, they are not much subject to disease, and instances of longevity, even to 100 years,

years, are said not to be rare amongst them. The air is dry and pure. The variations of the thermometer seldom exceed 14° , from 68° to 82° , in the inhabited part of the island. (See GUANCHES.) To the eastward of Santa Cruz, says Mr. Anderson (Cook's Third Voyage, vol. i. p. 22. &c.) the island appears perfectly barren. Ridges of hills run towards the sea, between which ridges are deep vallies, terminating at mountains or hills that run across and are higher than the former. Those that run towards the sea are marked by impressions on their sides, which make these appear as a succession of conic hills, with their tops very rugged. The higher ones that run across are more uniform in their appearance. The basis of the hills is a heavy, compact, blueish stone, mixed with some shining particles; and on the surface, large masses of red friable earth, or stone, are scattered about. The little earth, that appeared here and there, was a blackish mould. There were likewise some pieces of slag, one of which, from its weight, and smooth surface, seemed almost wholly metalline. The mouldering state of these hills is, without doubt, owing to the perpetual action of the sun, which calcines their surface. "After walking about three miles," says Mr. Anderson, "I found no alteration in the appearance of the lower hills, which produce great quantities of the euphorbia Canariensis. I met with nothing else growing there, but two or three small shrubs, and a few fig-trees near the bottom of the valley. Most of the laborious work in this island is performed by mules, horses being to appearance scarce, and chiefly reserved for the use of the officers: they are of a small size, but well shaped and spirited. Oxen are also employed to drag their casks along, upon a large clumsy piece of wood. In my walks and excursions I saw some hawks, parrots, which are natives of the island, the sea-swallow or tern; sea-gulls, partridges, wagtails, swallows, martins, blackbirds, and Canary birds in large flocks. There are also lizards of the common, and another sort; some insects, as locusts; and three or four sorts of dragon-flies." Mr. Anderson was informed that a shrub is common here, agreeing exactly with the description given by Tournefort and Linnæus of the tea shrub, as growing in China and Japan. Another botanical curiosity, mentioned by him, is what they call the impregnated lemon. It is a perfect and distinct lemon, inclosed within another, differing from the outer one only in being a little more globular. The leaves of the tree that produces this sort, are much longer than those of the common one; and it was represented to him as being crooked, and not equal in beauty. Mr. Anderson learnt also, that a certain sort of grape growing here is reckoned an excellent remedy in phthical complaints; and the air and climate in general are remarkably healthful, and particularly adapted to give relief in such diseases. This he endeavoured to account for by its being always possible to procure a different temperature of the air, by residing at different heights in the island: and he expressed his surprize that the English physicians had never thought of sending their consumptive patients to Teneriffe, instead of Nice or Lisbon. They reckon that 40,000 pipes of wine are annually made, the greatest part of which is either consumed in the island, or made into brandy, and sent to the Spanish West Indies and North America.

In the Embassy to China (vol. i.) the quantity of wine, consisting principally of white wine, said to be exported from Teneriffe, is about 25,000 pipes annually made in the island. Part is sent to South America: and the English take off a considerable quantity in return for manufactures; and the North Americans in payment of corn, slaves, horses and tobacco, which last article is contraband and smuggled.

Tobacco or snuff is in universal use; and that which is legally imported is sold at so high a price, that the temptation to smuggling is irresistible. The royal monopoly extends even to orchilla or archil, a substance used in dyeing. Formerly there was made at Teneriffe a great quantity of Canary sack, which the French call "vin de Malvasia," and we, corruptly after them, name Malmsey (from Malvasia, a town in the Morea, famous for such luscious wine.) In the 17th century, and still later, much of this was imported into England, and little wine is now made there except that described by Capt. Cook, and which he compares with Madeira, the latter being as much superior to the former, as strong beer is to small. But the great difference of price is a recommendation of it. Besides wine, which is the chief produce of the island, beef may be had at a moderate price. The oxen are small and bony, and the meat lean. Hogs, sheep, goats, and poultry, may also be bought at a moderate rate: and fruits, such as grapes, figs, pears, mulberries, plantains, and musk melons, are in great plenty. Their pumpkins, onions, and potatoes, are also very good of their kind. The Indian corn, which is their produce, and also their fruits and roots, may be had at a very reasonable rate. They have no plentiful supply of fish from the adjoining sea; but a considerable fishery is carried on by their vessels upon the coast of Barbary; and the produce of it sells at a reasonable price. Capt. Cook says that he found Teneriffe to be a more eligible place than Madeira for ships bound on long voyages to touch at. At Teneriffe they make a little silk; but unless we reckon the filtering-stones, brought in great numbers from Grand Canary, the wine is the only considerable article of the foreign commerce of Teneriffe. None of the race of inhabitants found here when the Spaniards discovered the Canaries, now remain a distinct people, having intermarried with the Spanish settlers; but their descendants are known from their being remarkably tall, large-boned, and strong. The men are in general of a tawny colour, and the women have a pale complexion, entirely destitute of that bloom which distinguishes our northern beauties. The Spanish custom of wearing black clothes continues amongst them; but the men seem more indifferent about this, and in some measure dress like the French. According to Capt. Cook, the peak of Teneriffe is situated in N. lat. $28^{\circ} 18'$, and upon this supposition its longitude will be

By	}	The time-keepers	$17^{\circ} \ 0' \ 30''$	} West.
		Lunar observations	$16 \ 30 \ 20$	
		Mr. Varila	$16 \ 46 \ 0$	

But if its latitude be $28^{\circ} 12' 54''$, as in Maskelyne's British Mariner's Guide, its longitude will be $13^{\circ} 30'$ more westerly. The variation (August 1776) by a mean of all Capt. Cook's compasses was found to be $14^{\circ} 41' 20''$ W. The dip of the N. end of the needle was $61^{\circ} 52' 30''$.

TENERIFFE, a town of South America, in the government of the Caraccas, and province of St. Martha; 80 miles S.S.W. of St. Martha. N. lat. $10^{\circ} 2'$. W. long. $74^{\circ} 30'$.

TENESMUS, in *Medicine*, an incessant and urgent desire to go to stool, while the evacuations are exceedingly scanty, of a mucous or bloody appearance, and are attended with scarcely any relief of the distressing sensation which preceded them. It may be brought on by any cause which excites excessive irritation in the rectum, either directly, or by sympathy with neighbouring organs, such as the bladder, uterus, prostate gland, or urethra. Thus it is frequently a symptom of a stone in the bladder, of inflammation of the neck of that organ, of fistula, of gonorrhœa virulenta, and also of pregnancy. In its most acute form, tenesmus more commonly

commonly occurs as a consequence of disease affecting the intestines themselves, and more especially of dysentery: it is also frequently excited by ascarides, or hæmorrhoidal tumours within the rectum. See DYSENTERY.

The treatment of this affection must of course be adapted to the nature of the irritation which has occasioned it; and the removal of the irritating cause will generally be followed by the cessation of the effect. When this, however, cannot be accomplished, the introduction of opium as a suppository into the rectum, or united with a starch glyster, will often procure essential relief.

TENESSEE, in *Geography*. See TENNESSEE.

TENESUR, a town of Egypt, on the west branch of the Nile; 3 miles S. of Amrus.

TENET, a particular opinion, dogma, or doctrine, professedly held by some divine, philosopher, &c.

The distinguishing tenets of the several sects in religion, and philosophy, see under the names of the sects themselves.

TENEZ, or TENES, in *Geography*. See TENNIS.

TENEZA, a town of Morocco; 43 miles W.S.W. of Morocco.

TENGA, in *Botany*, a name by which some authors have called the cocoa-nut tree, or palma indica nucifera of other writers.

TENGAN, in *Geography*, a city of China, of the first rank, in Hou-quang; 550 miles S. of Peking. N. lat. 31° 20'. E. long. 113° 17'.

TENGAPATAM, a town of Hindoostan, on the sea-coast, in the country of Travancore; 20 miles S.W. of Travancore.

TENGI, a town of Persia, in the province of Schirvan; 25 miles N. of Scamachie.

TENGILO, a river of Lapland, which falls into the Tornea, which, as well as the lake and mountain of Niemi, has been celebrated by Maupertuis for picturesque beauty.

TENGIS, a lake of Independent Tartary, about 140 miles in length by half that breadth, being the largest lake in Asia after the seas of Aral and Baikal. It is also called Balkash or Palcaté. This lake, with two others that are very considerable, belong to the Kalmucks subject to China.

TENGMO, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 10'. E. long. 21° 52'.

TENG-TCHOUEN, a city of China, of the second rank, in Yun-nan; 1182 miles S.W. of Peking. N. lat. 26° 2'. E. long. 99° 49'.

TENGZEGZET. See TENZEGZET.

TENIA. See TÆNIA.

TENIERS, DAVID, the elder, in *Biography*, was born at Antwerp in 1582. He received his education in painting in the school of Rubens, and under that great artist's immediate tuition, obtained the mode of preparing his grounds, and managing his materials. Intending to continue the study of historic painting, he went to Rome; but there abandoned it, and attached himself to his countryman, Adam Elsheimer, under whom he continued for six years to study landscape, and from him most probably acquired the neatness of pencilling for which his works are esteemed.

On his return to his native country, he blended the styles of both his masters, and employed the compound in a novel and ingenious manner, upon subjects original and at the same time agreeable; such as merry-makings, both interior and at the doors of cabarets; rural sports, cattle, sheep, and those who tended them; numerous groups and grotesque combinations; such as the temptation of St. Anthony, &c. For pictures of these kinds, he was fortunate enough to find

admirers and purchasers; and they would still have been the theme of admiration, had not his son, following the same track, have proved how possible it was to proceed infinitely farther. He died in 1649, aged sixty-seven.

TENIERS, DAVID, the younger, son of the foregoing artist, was born at Antwerp in 1610, and was initiated in the art of painting by his father; but he afterwards became a disciple of Adrian Brauwer, and is also said to have had the happiness and honour of receiving instructions from Rubens. The subjects and the style he adopted were, as we have said, the same with those employed by his father; but with a more fertile imagination, he produced compositions infinitely more varied and ingenious, with colouring and effect more vivid and engaging, more rich and transparent; and with a facility of execution perfectly enchanting. It is true they seldom exhibit much research of character or expression; what there may be of those qualities, was more probably a fortunate hit, than any result of meditation or intention. In this respect Jan Stein, and our own Wilkie, have as much the superiority over Teniers, as he possesses by the power of his execution.

At the first display of his powers he was not so successful as he merited, but it was not long that he lay neglected: the archduke Leopold being made acquainted with his merits, immediately distinguished him by his patronage; appointed him his principal painter; honoured him by making him a gentleman of his bed-chamber; presented him with a chain of gold, to which his portrait was affixed; and gave him the superintendance of his gallery of pictures, which contained works of the most distinguished masters of the Italian and Flemish schools. Of this gallery, Teniers made several pictures, in which he imitated the manners of the various masters so successfully, as to obtain the name of the Proteus of painting. He also amused himself by making compositions in the styles of different painters of renown, as Titian, Tintoretto, the Bassans, Rubens, &c.; and in their execution endeavoured to imitate the touch of those great men. These imitations are generally known under the name of pasticcios, and have frequently been mistaken for originals, and sold as such.

These were the amusements or indulgencies of idle fancy; his fame rests for more full and honourable support upon his original productions in his own proper style. He was a constant and faithful observer of nature; and in his favourite subjects, village festivals, fairs, and merry-makings, he has exhibited, with a most engaging freedom, the manners and characters of his countrymen. That he might conveniently mingle with the scenes he chose to represent, he established himself in the village of Perk, between Antwerp and Mechlin, and there, with a painter's eye, he observed the undigested impulse of the natural character of the lower class among the people, and has left many beautiful and pleasing remembrances of occurrences uninteresting, nay sometimes disgusting in themselves, but rendered engaging by his delightful mode of representing them. One peculiar charm there is to be found in the best pictures of Teniers, more perfectly obtained than in the works of other artists, and that is, the complete effect of atmosphere, silvery, pure, and natural; Claude de Lorraine himself does not surpass him; and this truth, though yielded on simple materials, in scenes flat and insipid in their forms, yet makes amends for their natural want of interest by its truth and simplicity.

In the interior of apartments, of the cottage, the cabaret, the guard-room, or chemist's laboratory, he is not less admirable by his clearness and precision than in his exteriors. He surpassed Ostade in his knowledge of perspective, and in his freedom, as much as he is excelled by the latter in truth.

of tone and completion of character. His pencil is exceedingly light and dexterous; and by continual practice upon the same system, he had acquired a promptness almost unparalleled. This freedom of execution enabled him to paint an immense number of pictures: it was not unusual for him to finish a picture in a day; and he used jocosely to observe, that to contain all the pictures he had painted, it would be necessary to have a gallery two leagues long. He not unfrequently assisted the landscape painters of his day, by putting figures into their pictures; and many works of Artois, Van Uden, Breughel, and many others, owe an increased value to this circumstance. His works are numerous in the collections of this country, and still bear very high prices. Teniers lived to the advanced age of eighty-four, and died at Brussels in 1694.

He had a younger brother named Abraham, who also painted the same kind of subjects in the same style, and from this circumstance his works are sometimes mistaken for those of David, though they are much inferior in taste and execution.

TENINE, in *Geography*, a town of South America, in the province of Tucuman; 20 miles S.W. of St. Yago del Estero.

TENIS, a lake of Russian Tartary, 60 miles in circumference. N. lat. $53^{\circ} 20'$. E. long. $74^{\circ} 4'$.

TENISON, THOMAS, in *Biography*, archbishop of Canterbury, was the son of the Rev. John Tenison, rector of Mundesley, in Norfolk, and born in the year 1636. He received his university education at Benet college, Cambridge, of which he became a fellow in 1662. Having officiated for some time as a tutor in his college, he was presented in 1665 to the cure of St. Andrew the Great in Cambridge, and continued his attention to his parochial duty during the plague. In 1667 he became chaplain to the earl of Manchester, and obtained a rectory at Huntingdonshire. His first publication appeared in 1670, and was entitled "The Creed of Mr. Hobbes examined, in a feigned Conference between him and a Student in Divinity." In 1674 he was chosen principal minister to the church of St. Peter's Mancroft, Norwich; and in 1678 he published a "Discourse of Idolatry," and in 1679 "Baconiana," or some pieces of the great lord Verulam, with a general account of his writings. As he was one of the royal chaplains in 1680, he graduated D.D., and was presented by the king to the vicarage of St. Martin's-in-the-Fields, London. As an antagonist to popery, the apprehension of which was then very prevalent, he wrote several works against it, and also against Socinianism; and whilst he was guarding the church against those whom he conceived to be its enemies, he acquired still greater honour by liberal benefactions to the poor, and by laying the foundation of an endowed school and public library, which he afterwards completed. He blended gravity with moderation to such a degree, as to command general esteem; and accordingly he was selected by the unfortunate duke of Monmouth to prepare him for his execution. He also conducted himself with so much prudence at court, that he is said to have had a personal interest even with James II. In the reign of William he avowed himself a friend to the dissenters and toleration; and after his promotion to the archdeaconry of London, he was appointed one of the commissioners for reviewing the Litany, with a view to the comprehension of the Separatists. He thus recommended himself to queen Mary, and by her interest he obtained the see of Lincoln, in 1691. Within three years he was unexpectedly advanced to the archiepiscopal see of Canterbury, more on account of his moderate and pacific principles, than for any pre-eminence to which he had at-

tained among men of letters or theologians. He attended queen Mary on her death-bed; and incurred the severe animadversions of the deprived bishop Ken, for not having reminded her majesty of her culpable want of duty to her father, by consenting to wear a crown which rightfully belonged to him. His conduct during the reign of king William was uniformly consistent with his principles, and both were so pleasing to his majesty, that he distinguished the prelate by many tokens of respect and confidence. In the reign of queen Anne, he was not, as we may naturally imagine, much regarded; more especially as he retained his just ideas of toleration, and resisted, though not without a share of obloquy, some of the high-church measures which were then countenanced. Nevertheless he displayed on various occasions his attachment to the established church, as well as his habitual bounty to the indigent. His last public act was the coronation of George I.; and afterwards sinking under the decay of advanced age, he closed his life at Lambeth, December 1715, in the seventy-ninth year of his age. As he left no issue, he bequeathed a considerable part of his property to charitable purposes. His character was uniformly respectable; and his conduct in difficult times was irreproachable and exemplary. Biog. Brit. Gen. Biog.

TENMENTALE, or TENMANTALE, in our *Ancient Customs*, originally signifies the number of ten men, which number, in the time of the English Saxons, was called a decennary; and ten decennaries made what we call an hundred.

These ten men were bound for each other to preserve the public peace; and if any of them was found guilty of a breach of it, the other nine were either to make satisfaction, or to bring the criminal before the king.

TENMENTALE was also used for a duty, or tribute, paid to the king, consisting of two shillings for each ploughland; probably thus called, because each person of the decennary was bound to see it paid.

TENNA, in *Geography*, a river which rises in the Apennines, and crossing the marquise of Ancona, runs into the Adriatic, about 4 miles E.N.E. of Fermo.

TENNE', TENNY, or Taconey, in *Heraldry*, a bright colour, made of red and yellow mixed; sometimes also called *brusk*, and expressed in engraving by diagonal lines drawn from the dexter to the sinister side of the shield, traversed by perpendicular lines from the chief; and marked with the letter 'T'.

In the coats of all below the degree of nobles, it is called *tenny*; but, in those of nobles, it is called *hyacinth*; and, in princes' coats, the *dragon's head*.

TENNEAH, in *Geography*, a town of Bengal; 35 miles N. of Midnapour.

TENNEBERG, a mountain of Saxony, in the principality of Gotha; 4 miles S.W. of Gotha.

TENNELIERES, a town of France, in the department of the Aube; 4 miles E. of Troyes.

TENNESSEE, one of the United States of America, situated between 35° and $36^{\circ} 30'$ N. lat., and $4^{\circ} 26'$ and $13^{\circ} 51'$ W. long. from Washington. It is bounded on the north by Kentucky and part of Virginia, on the south by Georgia and the Mississippi territory, on the east by North Carolina, and on the west by Missouri territory. Its extent from north to south is 102 miles, and from east to west 420 miles. Its area is 40,000 square miles, or 25,600,000 acres. The Indian claim has been extinguished in two portions of this country, the eastern and the western, comprehending one-third part of the state. The former is bounded north by Virginia, from the south-east corner of Kentucky, to the north-west of North Carolina; easterly by North Carolina;

TENNESSEE.

Carolina; westerly by Cumberland mountain, Emery's river, &c.; and southerly by a line marked from place to place, as a continuation of the Cherokee boundary. The western tract, thus purchased of the Indians, lies on Cumberland river, and is bounded north by Kentucky; easterly by a line running from the north-east to the south-west; and south and west by a line of several thousand angles, run according to the Tennessee Ridge, which separates the waters of the Cumberland from those of the Tennessee river. The general course of this ridge-line is first westerly, and then north-westerly; which, imagining the zigzag reduced into two straight lines, makes the figure of the tract a trapezium. The longest side is that adjoining Kentucky, the length of which, ascertained by measurement, is nearly 160 miles. The length of the easterly side is about 90 miles. The eastern is generally called the Holston settlement, and the western the Cumberland settlement, from those two prime rivers, which traverse the countries respectively. Between these settlements lies a spacious wilderness, which the Cherokees claim and traverse in hunting, and which, from one limit of their claim to the other, as the road goes, is about 70 miles wide.

This state, as it was erected and organized in 1796, is divided into three districts. The eastern settlement is divided into two districts, Washington the eastern district, and Hamilton the middle district. The western settlement is the third or Mero district. The number of counties, &c. may be seen in the following topographical table.

<i>East Tennessee.</i>		
Counties.	No. Inhabitants.	Chief Towns.
Anderfon	3959	
Bledsoe	8839	Marysville.
Blount	3259	Marysville.
Campbell	2668	
Carter	4190	Elizabethtown.
Claiborne	4798	Tazewell.
Cocke	5154	Newport.
Granger	6397	Rutledge.
Greene	9713	Greenville.
Hawkins	7643	Roger'sville.
Jefferson	7309	Dandridge.
Knox	10171	Knoxville.
Rhea	2504	Washington.
Roano	5581	Kingston.
Sevier	4595	Sevierville.
Sullivan	6847	Blountsville.
Washington	7740	Jonesborough.

The following counties have been laid out since the last census was taken:

Greenville,
Wayne.

The eastern part of this state is mountainous, the middle part hilly, and the western part mostly level. The climate among the mountains is said to be delightful; in the middle part, temperate and agreeable; in the western part, hot in summer, and mild in winter. The diseases to which the adult inhabitants have been most liable are pleurisy, rheumatism, and rarely agues and fevers; but, upon the whole, the inhabitants are generally healthy, and this salubrity of the state has been partly attributed to its having few stagnant waters. The principal rivers of this state are the Cumberland, the Holston or Holston, the Tennessee, the Clinch, the Notachuckey or Nolichucky, the French Broad, the Hiwassee, the Duck, the Redfoot, the Obian or Oby, the Forked Deer, and the Wolf. The chief of these rivers are described under their appropriate names. The mountains in this state are numerous; some of them, particularly the *Cumberland* (which see), or *Great Laurel Ridge*, are the most stupendous piles in the United States. Stone, Yellow, Iron, Bald, Smoky, and Unaka mountains adjoin each other, and form, in a direction nearly north-east and south-west, the eastern boundary of the state. In these mountains are innumerable caverns and cascades. North-west from these, and separated from each other by vallies from 5 to 15 miles wide, rise Bay's mountain, Copper Ridge, Clinch mountain, Powell's mountain, and Welling's Ridge. The four last terminate north of the Tennessee river, and these, as well as the others, are branches of Virginia mountains. They are all encircled by vallies, which open channels for rivers and roads for passage. Although the soil on the mountains is poor, that of the vallies is fertile; improving in the middle of the state, and in the western part becoming rich. It produces cotton, which is the staple commodity, and the principal article of export, tobacco, indigo, Indian corn, hemp, flax, rice, wheat, rye, oats, barley, and all kinds of vegetables in high perfection. The trees and plants found in this state are poplar, hickory, black and white walnut, all kinds of oaks, buck-eye, beech, sycamore, black and honey locust, ash, hornbeam, elm, mulberry, cherry, dogwood, sassafras, papaw, cucumber-tree, coffee-tree, and the sugar-tree. In the eastern district is a species of pitch-pine, useful for boards, timber, and tar. The under-growth, in many places, and especially in low grounds, is cane, some of which is upwards of 20 feet high, and so thick as to prevent any other plant growing: there are also Virginia and Seneca snake-root, ginseng, Carolina pink, angelica, fenna, lobelia, Indian physic, spice-wood, wild plum, crab-apple, haws, hazel-nuts, sweet anise, red bud ginger, spikenard, wild hop and grape vines. The glades are covered with wild rye, wild oats, clover, buffalo-

grafs, strawberries, and pea vines. On the hills, at the heads of rivers, and in some high cliffs of Cumberland, are found majestic red cedars; many of these trees are four feet in diameter, and forty feet clear of limbs. The commerce of this state is much facilitated by the rivers Tennessee and Cumberland, and their respective branches. Both these rivers empty into the Ohio, shortly after they pass the north boundary of the state. As the waters of the Cumberland from Nashville, and of the Tennessee from the Muscle Shoals to the Ohio, are navigable to the Ohio and Mississippi, the people of course, who live in this or the adjacent country, have the same advantages of water conveyance for trade, as those who live on the Ohio or Mississippi, to New Orleans or elsewhere. Besides, there is another probable avenue through which trade will be carried on with this and the adjacent country, which is from Mobile, up the waters of the Mobile river as far as it is navigable; thence by a land carriage, of about 50 miles at most, to Ocochappo creek, which empties into the Tennessee at the lower end of the Muscle shoals. The mouth of this creek is the centre of a piece of ground, the diameter of which is five miles, ceded by the southern Indians at the treaty of Hopewell, on Keewee, to the United States, for the establishment of trading posts. The iron works of Tennessee are large and numerous. The minerals of this country are iron-ore, limestone, coal, copperas, alum, nitre, lead, and some silver. Mineral springs, strongly impregnated with sulphur, are found in various parts of the country. On the waters of French Broad river is a fine, large, clear, medicinal, warm spring, the beneficial effects of which have been experienced by many persons who have resorted to it from the Carolinas, Georgia, and northern parts of Virginia. Salt is manufactured in considerable quantity, particularly on the north fork of Holston. Some herds of the bison are still found on the branches of the Cumberland river, though multitudes of them have been wantonly destroyed. The stag is occasionally found among the mountains; deer are scarce; bears, panthers, wild cats, and wolves, still remain. Beavers, musk-rats, and otters, are plentiful in the upper branches of Cumberland and Kentucky rivers. Racoons, foxes, opossums, and squirrels abound; as do also pheasants, partridges, pigeons, swans, wild turkeys, ducks, and geese; as well as bald eagles, parroquets, loons, cranes, and buzzards. The rivers are well stocked with all kinds of fresh-water fish.

The chief towns of Tennessee are *Knoxville*, *Nashville*, and *Jonesborough*; which see respectively.

The prevailing denomination of Christians in this state is composed of Presbyterians, intermixed with Baptists, Methodists, and Friends. With a view to mental and moral improvement, several schools and colleges are established in this state. Three colleges are established, one in Knox, one in Washington, and one in Greene county.

By the constitution of this state, which was formed and ratified at Knoxville, February 6, 1796, the legislative authority is vested in a general assembly, consisting of a senate and house of representatives. The number of representatives is to be fixed once in seven years, by the legislature, according to the number of taxable inhabitants, who are to be numbered septennially; the number of representatives not to exceed twenty-six, until the taxable inhabitants shall be 40,000. The senators are never to be less than one third, nor more than one half the number of the representatives, and are to be chosen upon principles similar to those for the choice of representatives. The election for members of both houses is biennial. The executive power of the state is vested in a governor, chosen by the electors of the members of the legislature: he is appointed biennially, and is

commander-in-chief of the army and navy, except in the service of the United States. Every freeman of 21 years of age, possessing a freehold in the county, and having been an inhabitant of the state for six months preceding, may vote for the members of the legislature. The house of representatives has the sole power of impeaching, and the senate of trying impeachments. The judicial power is vested in courts of law and equity. County officers are sheriffs, coroners, trustees, and constables. Military officers are to be elected by persons subject to military duty. Ministers of the gospel are not eligible to a seat in the legislature. No person who denies the existence of God, or a future state, can hold any civil office. The oath of allegiance and of office is to be taken by persons holding any office of trust or profit.

In the character of the inhabitants there is nothing peculiarly discriminating; but, in general, a great simplicity of manners prevails. Among the curiosities of the country we may reckon its numerous caves; and on the Enchanted mountain there are on several rocks impressions resembling the tracks of turkeys, bears, horses, and human beings, the latter having uniformly six toes each. Besides these, there are many other fanciful figures. The Indian tribes within and in the vicinity of this state are the *Cherokees* and *Chickasaws*; which see respectively.

The country now called Tennessee was included in the second charter granted by king Charles II. to the proprietors of Carolina; and in a subsequent division, it constituted a part of North Carolina. In 1754, at the commencement of the French war, not more than fifty families had settled here, who were either destroyed, or driven away by the Indians before the close of the following year. It remained uninhabited till 1765, when the settlement of it commenced; and in 1773, (such was the rapid accession of emigrants,) the country as far westward as the long island of Holston, an extent of more than 120 miles in length from east to west, was well peopled. In 1789, after some preparatory measures, the territory was ceded by the North Carolina legislature, on certain conditions, to the United States. In 1790, February 25, congress passed an act, accepting this cession; and, by another act, passed May 26, 1790, provided for its government under the title of "The Territory of the United States of America south of the River Ohio." On the 8th of June following, the president of the United States, by and with the advice and consent of the senate, appointed the Hon. William Blount, esq. a citizen of North Carolina, governor in and over the said territory; in which office he continued during the territorial government, and was president of the convention that formed the constitution under the title of "The Constitution of the State of Tennessee," of which we have given an abstract. The peace of the citizens of this territory has been disturbed many years past, by Indian wars, or incursions from the savages for the purposes of murder and plunder: they are now at peace. In the year 1796, this territory was in due form erected into an independent state, making the sixteenth in the Union. Morse. Melish.

TENNESSEE *Ridge*, the most considerable range of mountains in the state of Tennessee, separating the streams which run to the Cumberland and Tennessee rivers. In some parts it rises into abrupt hills, but in others admits of good roads. See CUMBERLAND *Mountain*.

TENNESSEE, called by the French *Cherokee*, and absurdly by others the *Hogohege* river, is the largest branch of the Ohio: it is 600 yards wide at its mouth. It rises in the mountains of Virginia, N. lat. 37°; and pursues a course of about 1000 miles south and south-west, nearly to

N. lat. 34°, receiving from both sides a number of large tributary streams. It then wheels about to the north, in a circuitous course, and mingles with the Ohio, nearly 60 miles from its mouth. From its entrance into the Ohio to the Muscle shoals, 250 miles, the current is very gentle, and the river deep enough, at all seasons, for the largest row boats. The Muscle shoals are about 20 miles in length. The bed of the river in this distance consists of broken stones, easily removed; and the navigation will admit of much improvement. At these shoals the river spreads to the width of three miles, and forms a number of islands, and is of difficult passage, except when there is a swell in the river. From this place to the "Whirl," or "Suck," where the river breaks through the Great Ridge, or Cumberland mountain, is 250 miles, the navigation all the way excellent. The Whirl, as it is called, is in about N. lat. 35°. It is reckoned a greater curiosity than the bursting of the Patowmack through the Blue Ridge. The river, which a few miles above is half a mile wide, is here compressed to the width of about 70 yards. Just as it enters the mountain, a large rock projects from the northern shore, in an oblique direction, which renders the bed of the river still narrower, and causes a sudden bend: the water of the river is of course thrown with great rapidity against the southern shore, whence it rebounds around the point of the rock, and produces the whirl, which is about 80 yards in circumference. Boats pass the whirl without danger or difficulty. Such is the situation of the shore, that boats ascending the river may be towed up. In less than a mile below the whirl, the river spreads into its common width, and except the Muscle shoals, already mentioned, flows beautiful and placid, till it mingles with the Ohio. Six miles above the whirl are the Chiccamogga towns, on the banks of the river, and of a large creek of the same name.

TENNIS, a pastime, or well-known game at ball, introduced among our ancestors about the year 1222, the sixth year of Henry III.; by persons of superior rank and family, who erected courts or oblong edifices for the performance of this exercise. Some have ascribed the etymology of the word *tennis* to the French language, and accordingly have derived the game from France. But the word *tenez* does not afford sufficient evidence of its French origin. For the holding or keeping possession of the ball is no part of the game; for, during the play, the ball is in continual motion, or passing from one to another. Others seek the etymology of the name and the origin of the game in a place in France called Tennois, (or, by a change of one letter, Sennois, in the district of Champagne,) where balls were first made, and the game, as it is said, first introduced.

TENNIS, in *Geography*, the ruins of a town of Egypt, situated on an island in a lake of the same name; once a large city, built by the Romans, on the site of a more ancient Egyptian town; 28 miles S.E. of Damietta. N. lat. 31° 2'. E. long. 32° 14'.

TENNIS, a lake of Egypt, 55 miles long, and about seven wide, which reaches from Damietta to Tineh, separated only by a narrow tongue from the Mediterranean.

TENNIS, or *Tnisi*, a sea-port of Algiers, in the province of Tremecen, at the mouth of a river which runs into the Mediterranean opposite a small island. Some geographers suppose this to be the ancient Jol, or Julia Cæsarea. Before the Turkish conquests, it was the metropolis of one of the petty royalties of this country; though a few miserable hovels are all that remains of it at present. Tennis has been long famous for the many loads of corn that are shipped off from thence to Christendom; but the anchoring ground (for

a harbour it cannot be called) that lies before it, being too much exposed to the north and west winds, is the occasion that vessels are frequently cast away, unless they meet with calm weather. The Moors have a tradition, that the Tennesians were formerly in such reputation for sorcery and witchcraft, that Pharaoh sent for the wisest amongst them to dispute miracles with Moses. It is certain that they are the greatest cheats in this country, and are to be as little trusted to as their road; 24 miles W. of Sherfshell. N. lat. 36° 33'. E. long. 1° 10'.

TENNOLTEI, a town of Thibet; 63 miles N.E. of Harachar Hotun.

TENO, a river of Norway, which runs into the sea, 56 miles W.N.W. of Wardhuys.

TENON, in *Building*, &c. the square end of a piece of wood, or metal, diminished by one-third of its thickness, to be received into a hole in another piece, called the *mortise*, for the jointing or fastening the two together.

Among joiners, &c. the tenon is made in various forms, square, dove-tailed, for double mortises, &c.

Vitruvius calls the tenons, *cardines*; dove-tailed tenons he calls *subscudes*, or *securiculæ*.

TENON-Saw. See SAW.

TENOR, TENOUR, the purport or contents, or transcript, of a writing, or instrument in law, &c.

Warrants issued for the confirmation of sentences, express, that they shall be executed according to their form and tenor.—It was impossible to retain so long a speech word for word, but the substance, or the tenor, is this.

TENOR, *Tenore*, Ital., in *Vocal Music*, implies the natural pitch or *tenour* of a man's voice in singing. In the vocal music of Italy, France, and Germany, there are three several tenor clefs in use at present: the *soprano* on the first line, for the highest part; the *contralto* on the third line, for the counter-tenor part; and the *alto tenore* on the fourth line, for the tenor part. (See CLEF.) In old music of the 15th, 16th, and 17th centuries, a tenor clef, called the *mezzo soprano*, on the second line, and even on the fifth line, frequently occurs, instead of the *baritono*, or F clef, on the third line.

In instrumental music, the tenor clef on the third line is used for the *alto viola*, and simply *viola*, or tenor part. The tenor clef on the fourth line frequently occurs in violoncello parts and harpsichord lessons of the early part of the last century; but at present, the high notes in the violoncello part, and in the base of pieces for the piano forte, are more frequently written in the treble clef.

TENOR, or *Tenorista*, is also used for a person who sings the tenor part in concert; and also for an instrument proper to play it.

TENORÉ *Indictamenti mittendo*, in *Law*, is a writ by which the record of an indictment, and the process thereupon, are called out of another court into the king's bench.

TENOS, in *Ancient Geography*, one of the islands called Cyclades, S.E. of the island of Andros, and very near it, N.W. of Delos, and N.E. of Syros. All historians agree in reporting that this island abounded with serpents, whence it took the name of Ophiussa, and in Greece that of the viper, or Tænia. It is said that the inhabitants must have abandoned it on this account, if Neptune had not rescued it from them. In consequence of this deliverance, they erected a magnificent temple to his honour, in a wood near the town of Tenos, and here they celebrated feasts in commemoration of him. This temple had very extensive rights of asylum, which were afterwards regulated by Tiberius. The island was also called Hydrassa, on account of its waters. The town of the same name was situated near the sea, in the S.W.

S.W. part of the island. See TINO.—Also, a town of Greece, in Thessaly.

TENOUR. See TENOR.

TENSA, in *Geography*, a river of Louisiana, which forms with the Washita and bayou Long, an island of an oval shape, about 50 miles in circumference. Immediately above this island, there is another, called Sicilly island, about 30 miles in circumference. At the lower end of Sicilly island, the bayou Tenfa spreads into a lake of 15 or 20 miles in length, and nearly parallel with the Mississippi. The Tenfa lake receives two considerable streams, the river Aux Boeufs, and the bayou Mascon.

TENSE, TIME, in *Grammar*, an inflexion of verbs, by which they are made to signify, or distinguish, the circumstance of time of the thing they affirm or attribute.

The affirmations made by verbs are different as to point of time; since we may affirm a thing *is*, or *was*, or *will be*: hence a necessity of a set of inflexions, to denote those several times; which inflexions our English grammarians call by a barbarous word, *tenses*; from the French *temps*: most other languages call them simply *times*.

There are but three simple tenses; the *present*, as, *I love, amo; the preter, preterite, or past*, as, *I have loved, amavi; and the future*, as, *I will love, amabo*.

But, in regard that in the preter tense one may either express the thing as just done or past, or indefinitely and barely that it was done: hence, in most languages, arise two kinds of preterite; the one *definitive*, marking the thing to be precisely done; as, *I have written, I have said*: and the other *indefinite*, or *aoist*, denoting a thing done indeterminately; as, *I wrote, I went*.

The *future* tense admits also of the same variety.

Besides the three simple tenses, others have been invented, called *compound* tenses; expressing the relation of the simple ones to each other.—The first expresses the relation of the *past* to the *present*, and is called the *preterimperfect* tense, because it does not mark the thing simply and properly, as done, but as imperfect, and present with respect to another thing past; as, *I was at supper when he entered; cum intravit, canabam*.

The second compound tense marks the time past doubly, and is therefore called the *plusquamperfect* tense; as, *I had supped; canaveram*.

The third compound tense denotes the future with respect to the past; as, *I shall have supped; canavero*.

The several tenses, or times, it is to be observed, are properly denoted in the Greek and Latin by particular inflexions; in the English, French, and other modern tongues, the auxiliary verbs *to be*, and *to have, être* and *avoir*, are called in. As to the Oriental languages, they have only two simple tenses, the *past* and *future*, without any distinctions of imperfect, more than perfect, &c.; but this renders those languages subject to abundance of ambiguities, from which others are free.

The ingenious Mr. Harris, in his *Hermes*, p. 119, &c. proposes the following theory of tenses. The tenses, he says, are used to mark present, past, and future time; either indefinitely, without reference to any beginning, middle, or end; or else definitely, in reference to such distinctions. If indefinitely, then we have three tenses, an *aoist* of the present, an *aoist* of the past, and an *aoist* of the future. If definitely, then we have three tenses to mark the beginnings of these three times; three to denote their middle; and three to denote their ends: in all, nine. The three first of these tenses he calls the *inceptive present*, the *inceptive past*, and the *inceptive future*. The three next, the *middle present*, the *middle past*, and the *middle future*. And the three last, the

completive present, the *completive past*, and the *completive future*. Thus the tenses in their natural number appear to be twelve; three to denote time absolute, and nine to denote it under its respective distinctions. The following examples will illustrate the application and use of each tense. *Aoist* of the present, γράφω, *scribo, I write*; *aoist* of the past, ἔγραψα, *scripsi, I wrote*; *aoist* of the future, γράσω, *scribam, I shall write*. *Inceptive present*, μέλλω γράφειν, *scripturus sum, I am going to write*; *middle or extended present*, τυγχάνω γράφων, *scribo, or scribens sum, I am writing*; *completive present*, γέγραφα, *scripsi, I have written*. *Inceptive past*, ἔμειλλον γράφειν, *scripturus eram, I was beginning to write*; *middle or extended past*, ἔγραφοι, or ἐπιτελεῖν γράφων, *scribebam, I was writing*; *completive past*, ἐγγράφηι, *scripseram, I had done writing*. *Inceptive future*, μελλήσω γράφειν, *scripturus ero, I shall be beginning to write*; *middle or extended future*, ἔσομαι γράφων, *scribens ero, I shall be writing*; *completive future*, *scripsero, I shall have done writing*. The author has particularly shewn what traces are discoverable in favour of this system, either in languages themselves, or in those authors who have written upon this part of grammar, or in the nature and reason of things. Dr. Ward enumerates seven tenses; viz. the present, past, and future imperfect; the past indefinite; the present, past, and future imperfect. See his *Four Essays upon the English Language*, p. 84.

TENSIFT, in *Geography*. See TANSIFT.

TENSION, TENSIO, the state of a thing bent, or the effort made to bend it.

Animals only sustain and move themselves by the tension of their muscles and nerves. A chord or string gives an acuter or deeper sound, as it is in a greater or less degree of tension.

TENSION, *Tensio, Taxis*, in the *Ancient Music*, was used to signify any pitch of sound, whether produced by intension or remission. Vide *Aristoxen*. p. 10. 13. edit. Meibom.

Aristoxenus observes, there are five things to be considered about sounds, viz. *τασις*, tension; *ἰπιλασις*, intension; *ἀνεσις*, remission; *ὀξύτης*, acumen; and *βαρυτης*, gravitas.

TENSITES, in *Geography*, a mountain of Africa, in the empire of Morocco, on the borders of Sugulmessa; 60 miles E. of Morocco.

TENSOR, in *Anatomy*, a name given to different muscles.

TENSOR *Palati*, a muscle of the soft palate. See DIGLUTITION.

TENSOR *Tympani*, a muscle of the internal ear. See EAR.

TENSOR *Vaginae femoris; musculus fasciae latae*; is an elongated and flattened muscle, narrow above, and becoming considerably broader below, situated at the upper and outer part of the thigh, and extending from the anterior superior spine of the ilium, to a short distance below the great trochanter. It is covered by a thin layer of the fascia; and it lies upon the rectus cruris, the vastus externus, and a small part of the gluteus medius and minimus, separated from them by a thin production of fascia, and by copious cellular tissue. Its front edge is parallel, above, with the outer margin of the sartorius: below, they are parted by an interval, occupied by the rectus anterior. The posterior edge is connected above to the gluteus medius; being separated from it below by cellular tissue. The upper extremity is attached to the anterior superior spine of the os innominatum, between the sartorius and the gluteus medius. The muscle, which is here narrow, passes obliquely downwards and outwards, growing considerably broader and thinner, and terminates below the great trochanter, at the angle of separation of the two layers of the fascia, between which it is situated: this angle is its point

point of insertion. Its upper attachment is by means of a tendon, from which the fibres run to the fascia.

It will bend the thigh on the pelvis; or carry it outwards; or rotate it inwards. When the thigh is fixed, it will incline the pelvis on that limb.

TENSTADT, in *Geography*, a town of Saxony, in Thuringia; 11 miles N.W. of Erfurt.

TENT, TABERNACLE, a pavilion, or portable lodge, under which to shelter, in the open field, from the injuries of the weather. See TABERNACLE.

The word is formed from the Latin, *tentorium*, of *tendo*, I stretch; in regard tents are usually made of canvas, stretched out, and sustained by poles, with cords and pegs.

Armies encamp under tents: these are made of canvas, and are of various sizes. A captain's tent and marquée is generally 10½ feet broad, 14 deep, and 9 high; those of the subalterns are a foot less; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The subalterns of foot lie two in a tent, and those of the horse one. The tents of private men are 6½ feet square, and 5 feet high, and accommodate five foldiers. The tents for the horse are 7 feet broad, and 9 feet deep; they hold five men, and their horse-accoutrements.

TENTS, *Bell*, are so called from their resemblance to a bell, and serve to shelter the fire-arms from rain.

To pitch the tents, is to fix them up ready for habitation, by the assistance of a ridge-pole, two standards, and a number of tent-pins.

Most of the Tartars and Arabs are wandering people, that always lodge under tents.

The Hebrews lodged forty years under tents in the deserts; which gave occasion to the Scenopægia, or feast of tabernacles.

TENT, *Dark*. See DARK.

TENT, in *Surgery*, signifies a roll of lint or linen, for preventing the healing of openings, from which matter, or some other fluid, makes its escape. Tents are also employed for dilating openings. There are some tents which are made of sponge that has been compressed into as small a compass as possible, while filled with fluid wax, and then allowed to become cold. These are called *sponge-tents*, and, on becoming warm, after being introduced into parts, they have the property of swelling in a remarkable degree. We shall only say further upon this subject, that, upon the whole, tents are not so much employed in modern as in ancient practice; and there is no doubt, that, unless their use be guided by moderation and judgment, they may do considerable mischief.

TENTAMOODY, in *Geography*, a town of Hindoostan, in the circle of Rajamundry; 35 miles S.E. of Rajamundry.

TENTATIVE is sometimes used adjectively: thus we say, a tentative *method*, meaning a kind of unartful or indirect method, which only proceeds by trying.

TENTATIVE is also used substantively, for an essay or effort, by which we try our strength, or sound an affair, &c. to see whether or no it will succeed.

In the French universities, tentative is the first thesis, or act, which a student in the theology-school holds, to shew his capacity: if he answers well in this, the degree of bachelor is conferred on him.

TEN-TCHEOU-FOU, or TEN-CHOO-FOO, in *Geography*, a city of China, of the first class, in the province of Chang-tong, having under its jurisdiction one city of the second class, and seven of the third. It is situated on a rising ground, and fortified by a strong wall round it, and defended by a numerous garrison. The fortifications of this city include a large space not occupied by buildings; and

when it was laid out, it must either have been expected that it would increase in houses to a greater number than that of those who now occupy it, or the vacant space was allotted for military or other exercises. The bay, or rather road, of Ten-choo-foo, is not only open to the east and west, but partially sheltered towards the north by groups of small islands, scattered about at different distances, from five miles to twice as many leagues, off the main shore. The Mi-a-tau islands are too distant to break off much of either wind or swell from that quarter. The anchoring ground consists in great part of hard sharp rocks; and at about 1¼ mile from the shore is a dangerous reef, covered at high water, extending nearly a mile east and west, round which the water shoals so suddenly as to render any approach to it very perilous. At Ten-choo-foo is constructed a kind of dock, or basin, for vessels to load or discharge their cargoes. The entrance into it is between two piers, and is from 30 to 40 feet wide. The ground near the coast of the Yellow sea is richly cultivated, and rises in a gentle ascent, which is terminated by high, broken, and barren mountains, apparently granitic. The passage between Ten-choo-foo and the Mi-a-tau islands is called in the chart the strait of Mi-a-tau, in which strait the rise and fall of the tide are about seven feet. Staunton's Embassy, &c. vol. i.

TENTER, TRIER, or Prover, a machine used in the cloth manufactory, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square.

It is usually about four feet and a half high, and, for length, exceeds that of the longest piece of cloth. It consists of several long, square pieces of wood, placed like those which form the barriers of a manège; so, however, as that the lower cross-pieces of wood may be raised or lowered, as is found requisite, to be fixed at any height, by means of pins. Along the cross-pieces, both the upper and under one, are hooked nails, called *tenter-hooks*, driven in from space to space.

To put a Piece of Cloth on the Tenter.—While the piece is yet quite wet, one end is fastened to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required: that other end being fastened, the upper lift is hooked on to the upper cross-piece, and the lowest lift to the lowest cross-piece, which is afterwards lowered by force, till the piece have its desired breadth. Being thus well stretched, both as to length and breadth, they brush it with a stiff hair-brush, and thus let it dry. Then they take it off; and, till they wet it again, it will retain the length and breadth the tenter gave it.

TENTERDÉN, in *Geography*, is a small market-town in the hundred of the same name, in the lathe of Scray, and county of Kent, England, situated 18 miles S.S.E. from Maidstone, and 56 miles S.E. by S. from London. N. lat. 51° 4' 8". E. long. 0° 41' 8". At a remote period it was incorporated by the name of the "barons of the town and hundred of Tenterden;" which style was changed to that of the "bailiff and commonalty," by letters patent of Henry VI., who at the same time annexed it as a member to the town and port of Rye, in Suffex, to which it is yet subject. Queen Elizabeth, in her forty-second year, granted the inhabitants a new charter, by which, in the place of a bailiff, &c. the future government of the town was vested in a mayor, twelve jurats, twelve common-council men, a chamberlain, and a town-clerk. The present town-hall, which is occasionally used as an assembly-room, was built about the year 1792; the old one having been burned by an accidental fire. The market-house is a small, mean edifice of timber, now little frequented; the market itself being almost dissolved, though still nominally

nominally held on Fridays. A large fair is annually held for the sale of cattle, wool, shop-goods, &c. According to the returns under the population act of the year 1811, the number of inhabitants in this town was 2786, that of houses 459. Many of the latter are respectable buildings, occupied by persons whose families have derived affluence from the grazing business carried on in the neighbouring marshes. The parish church is a spacious structure, and consists of a nave, north aisle, and chancel, with a well-built and lofty tower at the west end, on which is sculptured the arms of St. Augustine's monastery, to which foundation this church was appropriated in 1259. Besides the church, here are two places of religious worship for dissenters of different denominations. Dr. Harris mentions an ancient free-school, founded here by one of the family of Heyman of Somerfield, and records some donations made for its support. The trustees are the mayor and jurats, who, according to Haisted, are so inattentive to the charity, that not any children are now educated on this foundation.

The chapelry of Small Hithe, in Tenterden parish, was formerly, according to traditional report, a very considerable place, but is now reduced to a few farm-houses and cottages. The chapel was licensed by archbishop Warham, in 1509, "on account of the badness of the roads, and the dangers which the inhabitants underwent in their way to the parish church, from the waters being out."—*Beauties of England and Wales*, vol. viii. Kent, by E. W. Brayley.

TENTH, in *English History*. See **LAND-TAX**.

Tenths are said to have been first granted under Henry II., who took advantage of the fashionable zeal for croisades to introduce this new taxation, in order to defray the expence of a pious expedition to Palestine, which he really or seemingly had projected against Saladine, emperor of the Saracens; whence it was originally denominated the Saladine tenth. But afterwards fifteenths were more usually granted than tenths.

TENTH, *Decima*. See **FIRST-FRUITS**, and **TITHE**.

TENTHS, *Office of*, is kept in the Temple, under the direction of a receiver and his clerks.

TENTH, in *Music*, the octave above the third, and an octave below the seventeenth, or stop in the organ called the tierce. The tenth is a very pleasing consonance, but inferior in suavity to the third; for which reason the duets at the opera, since the principal first man's part has been performed by a tenor, have never given the audience that exquisite pleasure which they used to do, when sung by two sopranos.

TENTHREDO, in *Entomology*, a genus of the Hymenoptera order of insects, the characters of which are, that the mouth has a horny, arcuated mandible, within dentated; a straight jaw, obtuse at the apex; a cylindric, trifid lip, with four unequal filiform feelers; the wings flat, and tumid or slightly inflated; the piercers consisting of two serrated, scarcely prominent laminae; and the scutellum with two distant granules.

The larvæ of this genus resemble those of the order Lepidoptera, or real caterpillars; but are distinguished from them by their more numerous feet, which are never fewer than sixteen, exclusive of the three first or thoracic pairs. When disturbed or handled, they usually roll themselves into a flat spiral. They feed, like the caterpillars of the lepidoptera, on the leaves of plants; and undergo their chrysalis state in a strong gummy case or envelopment, prepared in autumn, out of which, in the ensuing spring, emerges the complete insect. The tenthredines form a numerous genus, and are divided into tribes or sections, according to the form of the antennæ. Gmelin reckons 143 species.

N. B. The European species are marked with a star *, and the English with a cross †.

Species.

A. *Antennæ clavated.*

* **FEMORATA**. Antennæ yellow; black body; hinder thighs largest; the larva green, with a blueish line on the back; and yellow at the sides.

* **MARGINATA**. Antennæ yellowish at the apex; black body; the hinder segments of the abdomen white at the margin.

LUTEA. Antennæ yellow; segments of the abdomen mostly yellow. This insect proceeds from a large green larva, of a finely granulated surface, with a double row of black specks on each side, and a dusky dorsal line bounded on each by yellow. It feeds on various species of willow, alder, and beech. The parchment-like case in which it envelops itself in autumn is of a pale yellowish-brown colour; and the chrysalis, which is of a pale dusky or brownish cast, exhibits the limbs of the future fly, in size equal to a common wasp, and of a yellow colour, bound with black; the antennæ rather short, and strongly clavated.

AMERINÆ. Body cinereous; abdomen beneath red; white lip. This insect is somewhat smaller than the preceding: its caterpillar, like that of the former, is of a green colour, and of a finely roughened surface, powdered with numerous whitish specks. Feeds on the willow.

TRISTIS. Black, with yellow antennæ, and wings brown at the apex; green larva, with an azure line on the back, black and yellow fringed.

VITELLINÆ. Abdomen above black; sides red; hinder thighs dentated; larva greenish.

LUCORUM. Antennæ black; body villous black. Found on the beech and alder.

* **FASCIATA**. Black; antennæ black; primary wings with a brown band.

* **SERICÆA**. Antennæ yellow; thorax black; abdomen brassy; larva green, with two yellow lines.

OBSCURA. Body smooth and black. Found in the groves of Sweden.

CONNATA. Black; abdomen with yellow bands. Found on the alder.

* **NITENS**. Antennæ yellow; abdomen green-blueish, shining. Suggested to be a variety of the sericea.

B. *Antennæ exarticulate, the outer ones thicker.*

CLAVICORNIS. Black; abdomen yellow; apex black. Found in North America.

ANNULATA. Black; abdomen yellow; hinder tarsi black, annulated with white.

* **ENODIS**. Antennæ smooth; body black-blueish; larva green, spotted with black, a rough lateral line yellow, sharp tail.

CILIARIS. Antennæ beneath ciliated; hinder legs white. Found in Germany.

* **USTULATA**. Body black; abdomen blueish; legs pale. On the canine rose. Larva green, with two white lines; head testaceous; obscure band.

† **CYANOCROCEA**. Head and thorax bright-blue; abdomen saffron-coloured.

† **ATRATA**. Black; back, zone, and three arcs, yellow-greenish.

BICOLOR. Black-blue; abdomen and base of the wings yellow; wings with a black band. Found in Austria.

* **MELANOCYRA**. Black; abdomen yellow; a small black line

TENTHREDO.

line on both sides of the anus; legs and soles yellow; wings with a black spot.

* **TRICOLOR.** Head and thorax black; wings and feet brown; abdomen yellow.

* **OCHROPUS.** Head, thorax, middle of the breast, and apex of the hinder legs, black; abdomen and feet yellow.

C. *Antennæ pectinates.*

CEPHALOTES. Black; abdomen with four yellow zones or belts. Found in Germany.

† **DORSATA.** Whitish; head and back of the thorax and abdomen black.

D. *Antennæ pennates.*

* **PINI.** Antennæ lanceolate, and thorax subvillous; larva blueish, and yellow at the tail end.

JUNIPERI. Antennæ obtuse; thorax smooth; larva green, pointed with black.

E. *Antennæ filiform, with from seven to nine Joints.*

AMERICANA. Thorax yellow; abdomen blue; wings black. Found in Surinam.

COSTALIS. Black, with the rib of the wings ferruginous. Found in Germany.

LATERALIS. Black; middle of the back red; sides white. Found on the flowers of Sweden.

† **ARQUATA.** Abdomen black; five arcs, with a band at the base and sides, yellow-greenish.

* **RUSTICA.** Black; abdomen with three yellow belts, the hinder two interrupted; larva cinereous, with triangular brown spots on the back.

* **SCROPHULARIÆ.** Antennæ yellow; abdomen with five yellow belts, the first more distant.

ABIETIS. Body black, with four ferruginous segments of the abdomen.

GERMANICA. Body black; thorax before and abdomen red. Found in the groves of Germany.

PADI. Black, with thighs and legs white.

CYNIPIFORMIS. Green-brassy; yellow feet; hinder thighs brassy.

CERASI. Body black; scutellum and feet yellow; larva gelatinous, black.

SALICIS. Body variegated. Found on the elder and willows.

FLAVICORNIS. Yellow; head and tail black. Found in Germany and Italy.

LUTEICORNIS. Black; with antennæ, mouth, base of the abdomen, and legs, yellow.

MESOMELAS. Abdomen yellowish; back black; arcs yellowish.

PUNCTUM ALBUM. Body black; abdomen at the sides white; hinder thighs red. Found in Germany.

† **BLANDA.** Black; abdomen in the middle red; hinder thighs with a white spot.

QUADRIMACULATA. Black; hinder feet red; two spots at the base white.

* **RUFIPES.** Body black; abdomen with two yellow belts; feet red.

* **CAMPESTRIS.** Body black; abdomen with an unequal yellow belt; antennæ and legs yellow.

* **ATRA.** Body black; feet red.

* **VIRIDIS.** Body green; abdomen above brown.

* **OVATA.** Body black; thorax above red; larva greenish, sprinkled with a kind of white powder.

ALNI. Body black; head and thorax red.

* **CÆRULESCENS.** Violet; abdomen yellow; wings with a brown spot.

VOL. XXXV.

* **PAVIDA.** Black; the abdomen with three segments, and feet ferruginous; larva green, sprinkled with white farina; head yellow.

* **ROSÆ.** Black; abdomen yellow, and ridge of the primary wings black; larva yellow, pointed with black.

* **BICINCTA.** Body black; belt of the abdomen, anus, mouth, and legs yellow.

CINCTA. Body black; the abdomen with a white belt; perhaps a variety of the former.

* **LIVIDA.** Body black; antennæ before the apex white.

ALBICORNIS. Black; antennæ at the apex white; legs testaceous; wings at the apex brown. Found in Italy.

GONOGRA. Body black; knees testaceous. Found in Germany.

NIGRA. Whole body black. Found at Upsal.

* **ÆTHIOPS.** Smooth, black; with the four fore-legs pale.

RAPÆ. Body black; belly, feet, and scutellum whitish.

SEPTENTRIONALIS. Feet posterior, compressed and dilated; larva gregarious, green, spotted with black; yellow apices.

OPACA. Black; thorax with a spot on both sides, red at the apex. Found in the gardens of Sweden.

CARBONARIA. Black, with a white mouth; fore-legs testaceous. Found in Germany.

* **NASSATA.** Yellow; scutellum and point of the wings white.

* **12-PUNCTATA.** Body black, with twelve white points.

CAPRÆ. Yellow; head, thorax, and abdomen above, black; wings with a yellow point.

MORIO. Black; with pale feet. Found in Germany.

ANNULARIS. Black, shining; antennæ white at the apex; legs ferruginous. In the gardens of Austria, perhaps a variety of the livida.

FERRUGINEA. Antennæ black, annulated with white; body ferruginous; thorax, breast, and vertex black. Found as the last.

CRASSA. Black; feet and double points under the scutellum elevated, red. In Austria and Carniola.

ALBICINCTA. Black; the belt at the base of the abdomen and legs with a ring milky. In Austria and France.

VESPIFORMIS. Antennæ yellow; all the segments of the abdomen with yellow margins. In Austria.

SEMICINCTA. Black; the belt of the abdomen broken behind, yellowish; the feet and abdomen beneath yellow. In Austria.

VIENNENSIS. Black; abdomen with five yellow belts; the base of the antennæ fulvous. In Vienna.

RIBIS. Black; legs and apophyses of hinder thighs white at the exterior side. In Austria.

FULIGINOSA. Black, with fuliginous wings. In Austria.

DEALBATA. Black; the abdomen on both sides marked with a white spot, hinder thighs clavated, yellowish. In Austria.

ALNETI. Yellow; abdomen above black. In Austria.

HÆMATODES. Black, thorax before on both sides red. In Austria.

ERYTHROGONA. Black; the apex of the thighs and base of the legs red. In Austria and France.

FULVIVENTRIS. Black; with red and deep yellow abdomen. Found in Austria and Carniola.

FULVIVENIA. Black; with the exterior margin of the wings fulvous, or deep yellow. Found at Vienna.

* **SULPHURATA.** Black; antennæ subclavated; four fore-

TENTHREDO.

fore-feet sulphureous; the hinder soles with three intermediate white joints.

* *FLAVEOLA*. Antennæ subclavated, black; base, mouth, sides, and five first segments of the abdomen and feet, yellow.

* *ANNULATA*. Yellow; antennæ subclavated, black; apex of the thighs and soles annulated with black.

* *RUBIGINOSA*. Black; antennæ subclavated, and base with feet yellow; third, fourth, and fifth segments of the abdomen ferruginous,

* *SUBULATA*. Black; antennæ subulate at the apex; second to the fifth segments of the abdomen, as far as the hinder margin, legs and soles, yellow, and these annulated with black.

* *MUCRONATA*. Black, with the seven-knotted antennæ and abdomen yellow; the last segments from the second to the fourth black; the apex of the wings brown.

* *VARIA*. Black; mouth, scutellum, and scutellar spots, white; the hinder segments of the abdomen and feet ferruginous.

* *SANGUINOLENTA*. Black; with the hinder feet fan-guineous.

* *DEALBATA*. Black; the three last joints of the antennæ and jaws white; legs and soles yellow.

* *CANESCENS*. Grey-downy, brown, with grey wings.

* *BIFASCIATA*. Brown, with black thorax; mouth, scutellum, and four spots at the scutel, white; abdomen with two interrupted yellow bands; margin of the wings and feet yellow.

* *BRACCATA*. Black, with red thighs; the base of the four hinder legs, and the three penultimate joints of the antennæ, white.

* *RUFIPES*. Black; the base of the abdomen, with a spot on both sides, and jaws, white; four fore-legs red.

* *MELANOLEUCA*. Black; mouth, thorax with a small line on both sides before the wings; a spot on the hinder thighs; legs, the sides of the abdomen from five to seven segments, and apex, white.

* *MELANOCYTRA*. Black; mouth, four fore-feet, and base-flexure of the hinder thighs, yellow.

* *LEUCOPUS*. Black; the base-flexures of the thighs white; four anterior legs without, and middle of the hinder, white.

* *VARICORNIS*. Black, with red feet; fourth and fifth joints of the antennæ and hinder legs at their base, white.

* *OBSCURA*. Brown; with the rib of the wings as far as the spot and feet testaceous.

* *LIMBATA*. Black; the hinder margins of the segments of the abdomen white; feet reddish.

* *EXALBIDA*. Black; with feelers and four legs obsoletely white.

* *FERRUGINOSA*. Black; the antennæ ferruginous forwards; the base and anterior margin of the wings, the first and fifth segment of the abdomen, the legs and soles, white.

* *ANGUSTA*. Black; body narrow and grey-downy.

* *LUTESCENS*. Black; with the abdomen beneath and feet yellow-reddish.

* *ALBIPES*. Black; with legs and soles white.

* *FLAVIVENTRIS*. Black; mouth white; abdomen yellow; back and apex black; feet testaceous.

* *PICEA*. Pitchy; anterior legs before, spot of the hinder thighs, and base, white; hinder feet red; the knees and soles black.

* *FUSCIPES*. Black; feet red; posterior soles brown.

* *BIMACULATA*. Pale; eyes, abdomen above the base, breast and two spots, black.

* *LATA*. Broad, black; the posterior segments of the abdomen white, from the second to the fifth interrupted.

* *ANNALICORNIS*. Pale, the antennæ spotted with black at the base; vertex of a branchy figure, eyes, and the conjugate points at the back of the thorax and abdomen, black.

* *SCRIPTA*. Pitchy; mouth, and on the middle of the fore-part of the thorax the mark resembles V; the spot on both sides the scutellum white; two scutellar points white; feet, and under margin of the segments of the belly, yellow.

* *LITERATA*. Black; segments of the abdomen from the second to the fifth in the back, ovated spot on both sides and margins white; anterior feet, and four hinder legs on the fore-part, white.

* *MELANORRHEA*. Black, with yellow abdomen; the transverse spots of the back and anus black.

* *GEMINATA*. Black, with geminated antennæ, and joints and legs pale.

* *OCHROGUSTES*. Pitchy; with the abdomen beneath and feet yellow.

* *RUFICAPILLA*. Head and thorax red; the posterior margin of the latter and eyes black; the abdomen and feet yellow.

* *DUBIA*. Black; thorax before red; joints whitish.

* *PALLESCENS*. Black; mouth and feet pale.

F. *Antennæ fetaceous; many Joints.*

ERYTHROCEPHALA. Body cæruleous; head red.

* *SYLVATICA*. Body black: feet and marks of the thorax yellow.

* *NEMORALIS*. Body black; segments of the abdomen white at the side.

* *CYNOSEATI*. Body black; feet ferruginous, hinder annulated with white and black.

SIGNATA. Pale; thorax and three dorsal longitudinal spots black. Found in Germany.

POPULI. Black-blueish; mouth, feelers, and legs yellow.

VAFRA. Head black, variegated with white; feet testaceous. Found in Sweden.

RETICULATA. Wings varied with pale and brown, with elevated veins, white and reticulated. Found in Finland.

* *BETULÆ*. Body red; thorax, anus, and eyes black; wings behind brown.

* *FLAVA*. Yellow, with the spot on the wings ferruginous.

HÆMORRHOIDALIS. Black; with the anus and feet testaceous. In Germany.

† *NEMORUM*. Middle of the abdomen red; scutellum and point on the wings white.

DEPRESSA. Head and thorax black; marks yellow; abdomen and feet ferruginous. In Austria and France.

LINEARIS. Black; legs, and five bands of the filiform abdomen, yellow. In Austria.

BIPUNCTATA. Antennæ sub-fetaceous; nine joints black, and two points of the black scutellum white.

G. *Of doubtful Order.*

INTERCUS. Black; with yellow feet and subclavated antennæ.

RUMICIS. Found on the dock.

ULMI. Found on the leaves of the wild elder.

PRUNI. Found on the plum-tree.

LONICERÆ. Brown, tomentose, shining, with subclavated antennæ, and subferruginous wings.

* *POLYGONA*. Black; antennæ subclavated with eighteen knots;

knots; the hinder margin of the segments of the abdomen from the third to the fifth yellow-greenish; the thighs black; the face anterior at the apex and the legs yellow; the hinder at the apex black; the soles yellow; the linear abdomen compressed.

TENTOLI, in *Geography*, a town of the island of Celebes, near the north extremity, on the west coast, which gives name to a road. N. lat. 1°.

TENTORES, among the Romans, were persons appointed to hold the clothes of the charioteers that contended in the circus.

TENTUGAL, in *Geography*, a town of Portugal, in the province of Beira; 7 miles W.N.W. of Coimbra.

TENTYRA, or TENTYRIS, in *Ancient Geography*, a town of Egypt, and capital of a nome, which took the name of *Tentyrites*, according to Strabo, Pliny, Ptolemy, and Steph. Byz.

TENTZEL, WILLIAM-ERNEST, in *Biography*, a German antiquary and historian, was born, in 1659, at Greussen, in Thuringia, and finished his education at Wittemberg, directing the course of his studies to philosophy and the Oriental languages, and also to history, both sacred and profane. In 1685 he was appointed a teacher in the gymnasium at Gotha, and entrusted with the care of the duke's collection of antiquities and coins. In order to qualify himself for the more honourable discharge of his duties as historiographer to the house of Saxony of the Ernestine line, to which office he was appointed in 1696, he visited various courts in Germany, and carried on an epistolary correspondence with many distinguished foreigners. In 1702 he removed to Dresden, where he was made historiographer to the elector of Saxony, king of Poland, by whom he was honoured with the title of counsellor; but his manners not being adapted to a court, he obtained leave to retire. What remained of his life was devoted to literary pursuits; and he died, very poor, in November 1707, in his 49th year. His works were numerous, among which we may reckon the following: *viz.* "De Phenice," Vitemb. 1682, 4to.; "De Ritu Lectionum Sacrorum," Vitemb. 1685, 4to. a work highly commended by Bayle; "Judicia Eruditorum de Symbolo Athanasiano studiosè collecta et inter se collata," Francf. et Lips. 1687, 12mo.; "Animadversiones in Casimiri Ordine Supplementum de Scriptoribus Ecclesiasticis," 1688, 12mo.; "Casparis Sagittarii Historici Saxonici Historia Gothona plenior, &c." Jena, 1700, 4to.; "Supplementum Historiæ Gothonæ," *ibid.* 1701, 4to.; "Supplementum Hist. Goth. secundum," *ibid.* 1701, 4to.; "Saxonia Numismatica, Pars I." Francf. et Lips. 1705, 4to.; "Pars II." 1705. Tentzel was also a contributor to several literary journals. Gen. Biog.

TENUIROSTRÆ, in *Ornithology*, the name of a genus of small birds, which feed on insects, and have slender and sharp beaks; of this genus are the lark, swallow, red-breast, and a number of others. Ray's *Ornithology*.

TENUME, in *Geography*, a town of Arabia, in the province of Nedsjed; 40 miles N. of Aniza.

TENURE, in *Agriculture*, the manner in which proprietors and tenants hold their lands, &c. of their landlords, or other persons.

It may be noticed, that the tenures of lands are extremely various in almost every district of the kingdom, being, however, chiefly *freehold*, *free-farmhold*, *copyhold*, *long-leasehold*, or *life-leasehold*, though there are many other local sorts of tenures of land. The freehold is most probably in the largest proportion over the whole country, the copyholds in the next, and the leasehold tenures in the smallest extent. It

has been remarked in the Shropshire Agricultural Report, that it appears beautiful in theory, that there should be one rule of descent in a kingdom only, one tenure of property, and one scale of political rights; but that it may be doubted whether so much uniformity is suitable to an imperfect state; or at least to our present degree of improvement. At all events, irregularities that are not attended with much practical inconvenience, should not be pointed out as obnoxious, in a scheme that has produced so much positive happiness, and so much comparative good, as the constitution of these kingdoms has afforded.

It is stated too, in the Agricultural Survey of Essex, that freehold estates are the most valuable to the immediate proprietor, there can be no doubt; but the purchaser of a copyhold may remember, that the original purchase is by so much the lower; and whether he lets the occupation to a tenant, or farms and cultivates it himself, he may possibly make as good interest of his capital as if he had bought a freehold. Perhaps, also, its general and final utility to the public, may be nearly or quite the same. This, the writer thinks, is certain, that copyhold estates, whether in the hands of the proprietors or tenants, are as well cultivated as the free, excepting only in the article of timber, and even in that the difference is seldom visible. The like may be said of leasehold estates, and even of those in mortmain.

In Hertfordshire, where a large portion of the property is held by copyhold tenure, with a fine certain or at the will of the lord, but which fine never exceeds two years' rent, the land sells at about six years' purchase under the price of freehold, according to the Report of the state of agriculture for that district. And it is further suggested in the latter of the two former of the above agricultural surveys, that, with regard to the tenures by which the more temporary occupiers hold their farms, they are, as already observed, extremely various, some upon leases of longer or shorter duration, some without any lease at all, agreeably to the taste and pleasure of the landlord; though by far the greatest number, especially of those in the possession of the smaller proprietors, are let upon leases of from eight or ten to twenty-one years. And it is observed, from what has been done in Norfolk and other counties where the tenures are of more length, as from seven to twenty-one years, that the improvement of the land is much connected with the practice of such tenures. And it is likewise suggested in the Gloucester Report on Agriculture, that it were much to be wished that a general rule could be adopted for the commencement and end of tenures; as it would ultimately, the writer thinks, be highly advantageous to landlords and tenants, and will probably be one result of the labours of agricultural societies.

Some suppose the freehold tenure to possess the most numerous advantages, with the fewest inconveniences, of any sort of holding. But many are of opinion that some other kinds are equal to it, or nearly so. The forms of tenure throughout most of the southern parts of England, are principally those of the freehold, copyhold, life-lease, church-lease, and college-lease kinds, both for lives and years. In Cornwall they are for the most part freehold, with the exception of the lands of ecclesiastical corporations and ancient duchy land, which is equivalent to copyhold in fee, held under the duke of Cornwall, subject to a small annual rent. This sort of land passes by surrender in the duchy courts, nearly in the same form as other copyhold lands. But the modern duchy is different from the above; the occupiers being lessees under the duke, and, in general, are purchasers of an interest in the land during the continuance of the longest liver of three lives, the consideration being, in part,

a fine paid at the time of the grant, and also a reserved rent during the continuance of the lease.

There are three different kinds of church-lease in this district; as demises to tenants for the longest of three lives; the considerations being money and reserved rents; demises to manorial tenants for three lives in the same way; the takers having the liberty, during the whole time, to under-lease to other tenants in the manner of copyholds for three lives; and grants of leases for twenty-one years absolute, giving fresh leases at the end of every seven, which is a renewal of the first. These are first made in consideration of fines and reserved rents, but in the renewals fines only.

In the same district, it has been much the custom, in respect to the tenure of tenants, to grant leases for lives, for the term of ninety-nine years, determinable on the death of the longest liver of three lives, to be named by the taker. On the death of one of the lives named in the lease, it was usual for the landlords to consent to the adding a new life to the two which remained. The consideration in the primary grant was uniformly a fine in hand of from fourteen to eighteen years rent of the landed estate, with a small reserved rent, and suit and service to the manor court; the renewal commonly a fine only of three years' rent for one life, or seven for two lives, without any alteration of the other rent.

A large proportion of the lands here are now held by the tenantry under these leases or tenures, but it must be noticed, that the number of new grants, or the renewal of old ones, is on the decrease; and seldom takes place, unless under particular circumstances and motives.

The holders under these leases or tenures, which are called leaseholds or fine-leases, are constantly subjected to all taxes and repairs of every kind, excepting that a small proportion of the land-tax in some manors is repaid the tenant, as the land-tax of the reserved rent. Under the property-tax, they were rated both as proprietor and occupier, except only that the landlord was liable to the property-tax for his reserved rent.

It admits of some doubt whether this mode of leasing or holding property be more detrimental to the lord, the tenant, or the public in general; but it is certainly a very injudicious and unwise method of proceeding, as it is highly injurious to the agriculture of the county, though at first sight the security and great length of the leases might be supposed to have the contrary effect. It is found, however, in practice, that the circumstance of most of the holders under these leases having not only exhausted in their purchase and renewal the whole of their capitals, but often considerably more raised on them with great disadvantage, counteracts every good that might otherwise have been expected. It is asserted that, in common, cultivators of this sort, from the want of capital and other means, as well as the speculative nature of all such tenures, are necessarily feeble and spiritless, and that they live worse, work harder, and are more inconvenienced, than any other kind of holders of land. And that where the landlords do not renew, they are frequently sufferers from the dilapidated and exhausted state of the premises.

It is also remarked by Mr. Vancouver, in his Account of the Agriculture of the County of Devon, in regard to these kinds of life-lease tenures, that the mischievous consequences inseparably connected with, and resulting from, the want of agricultural knowledge in those who have the direction and management of such estates, and who, to cover the want of the necessary qualifications of a land agent, most commonly advise the proprietors to grant those life-hold tenures so frequently heard of in this county and South Wales, are

more injurious and extensive than is generally apprehended. The same capital employed in the purchase of a lease for ninety-nine years, determinable on three lives, applied to the stocking, cultivating, and improving a more extensive occupation held at a fair annual rent, and under an encouraging term of years, must, it is supposed, produce, in the contemplation of such property, very different emotions in the mind of the owner: to the occupier the results are infinitely more advantageous; and to the public at large, a more abundant supply is produced than can possibly be derived from a capital employed in the purchase of a more narrow occupation on an eventually undisturbed possession of ninety-nine years. But notwithstanding, an opinion prevails with some noblemen and others in this county, that it is better to realize at forty years' purchase, than to suffer the lifehold tenures to fall in without renewal. Fortunately for the future improvement and prosperity of the county, the writer says, this species of tenure is become much lessened within the last twenty years. In order to accomplish this preposterous object of the tenant's indolence and pride, it is observed, he will employ his last shilling, and incur very heavy obligations among his friends and neighbours, to pay eighteen years' purchase for a lease only of that very farm, the fee of which might readily have been bought for about one-third more. Destitute of capital, and encumbered with obligations contracted with his family and friends, the farmer enters his new occupation, depending upon casual and agistment stock for the consumption of his pasture herbage. Having little or no reserved rent to provide for, the efforts of himself and family are directed to the annual cultivation of so much of his land as will pay the parochial and other small disbursements, and supply the bare wants of the most comfortable life it is possible to conceive, leaving no brighter prospects to his offspring, than what the lapse of ninety-nine years may do, by terminating a lease so injudiciously purchased. The same is the case with these sorts of tenures in many other districts of the kingdom.

There is a great number of tenures besides the above sorts in the midland and more northern counties, some of which are very curious and singular. Tenures under the crown are likewise met with in these as well as most other parts of the kingdom.

In that part of the country usually denominated Scotland, the tenures by which lands are principally held may be classed and considered as those of superiority, property, and tack; the first of which is merely nominal, and goes no farther than that of conferring the right of franchise; the second is a valuable tenure of land, as yielding and implying the full use and command of it to the subject for all the purposes of human life, excepting merely political power, which is attached as above, and may or may not be attached to the property; and the last is the tenure for a term of years, by which professional farmers hold land from proprietors for the purposes of agriculture. The origin of these sorts of tenures, which seem to have been of a military or feudal nature, is more fully explained in Finlatter's Agricultural Survey of the County of Peebles, to which the inquirer on this subject is referred.

TENURE, *Tenura*, in Law, the manner or condition in which a tenant holds lands or tenements of his lord; or the services performed to the lord, in consideration of the use and occupancy of his lands.

The kinds of service, and consequently of tenures, are almost infinite. See SERVICE.

Those for lands held of the king are either *great*, or *petty sergeantry*, *in capite*, *knight's service*, &c.

Those held of the lords were very various, *base*, *frank*, &c. by *homage*, *focage*, &c. See BASE, FRANK, &c.

The common tenures at this day are, fee-simple, fee-tail, by courtesy, in dower, for life, or for years, or by copy of court-roll.

TENURE, *Barons by ancient*. See BARON.

TENURE, *Disturbance of*, is a species of injury which consists in breaking that connection which subsists between the lord and his tenant, and to which the law pays so high a regard, that it will not suffer it to be wantonly dissolved by the act of a third person. If, therefore, there be a tenant at will of any lands or tenements, and a stranger, either by menaces or threats, or by unlawful distresses, or by fraud and circumvention, or other means, contrives to drive him away, or inveigle him to leave his tenancy, this the law very justly construes to be a wrong and injury to the lord; and gives him a reparation in damages against the offender by a special action on the case. Blackst. Com. vol. iii.

TENUTE, Ital. in *Music*, generally written *ten*, from the Italian verb *tenere*, to hold on, sustain to the last moment of a note's duration. See SOSTENUTO.

TENYA, in *Geography*, a town of Africa, in the country of Fouta. N. lat. $10^{\circ} 15'$. W. long. $10^{\circ} 25'$.

TEN-YANG, a town of Corea; 73 miles E.S.E. of King-ki-tao.

TENZEGZET, a town of Algiers; 16 miles S. of Tremecen.

TENZYN, a town of Poland, in the palatinate of Cracow; 20 miles W. of Cracow.

TEOATZINCO, a town of Mexico; in the country of Tlascala, where a bloody battle was fought between the natives and the Spaniards under Cortez; 20 miles E. of Tlascala.

TEOLO, a town of Italy, in the Paduan; 7 miles S.S.W. of Padua.

TEOLY, a town of Hindoostan, in the circar of Gohud; 15 miles S.E. of Gwalior.

TEOMAHAL, a small island in the Sooloo Archipelago. N. lat. $6^{\circ} 15'$. E. long. $120^{\circ} 51'$.

TEONA, a small island near the west coast of Scotland. N. lat. $56^{\circ} 47'$. W. long. $5^{\circ} 50'$.

TEOPISCAN, a town of Mexico, in the province of Chiapa; 60 miles S.E. of Chiapa dos Espagnols.

TEOS, in *Ancient Geography*, a town of Asia Minor, in Ionia, on the southern coast of a peninsula, which became an island when the sea was high or much agitated. It was situated over-against the isle of Samos, S.W. of Smyrna, and E. of the promontory of Coryceon. It is celebrated for having been the birth-place of Anacreon. The inhabitants were renowned for their courage: they preferred abandoning their city to living under the tyranny of the Persians. Teos was treated with mildness by the Roman emperors. Bacchus had a magnificent temple here, which Vitruvius has particularly described. Here also was held a general council for the management of all the affairs of Ionia, because this city was in the centre of Ionia.—Also, the name of a town of Scythia.

TEOWENISTA CREEK, in *Geography*, a river of Pennsylvania, which runs into the Alleghany, about 5 miles below Hickery.

TEPAPA. See TAROATAIHETOOMO.

TEPEACA, in *Geography*, a town of Mexico, in the province of Tlascala; 15 miles S.S.E. of Puebla de los Angeles.

TEPEGUANA, a district of New Brasil, situated on the Nazas.

TEPELLENE', a town of Albania, the birth-place and favourite residence of Ali, situated on the banks of a river, which at the distance of 60 miles from the sea appears

to be as broad as the Thames at Westminster bridge. The streets of the town, containing about 400 ill-built houses, are extremely dirty; but the palace of the vizier is very magnificent.

TEPE-MAXTLATON, in *Zoology*. See FELIS Tigrina.

TEPETISTAC, in *Geography*, a town of Mexico, in the province of Guadalajara; 60 miles N. of Guadalajara.

TEPETOTOTL, in *Ornithology*, the name of a Brazilian bird of the gallinaceous kind, more usually called *mituporanga*. See CRAX Aleator.

TEPHLIS, or TELIHIS, in *Ancient Geography*, a town of Asia, in the vicinity of Media.

TEPHRIA, in the *Natural History of the Ancients*, a name given to the grey ophites.

TEPHRICA, in *Ancient Geography*, a town of Asia, in the neighbourhood of Cilicia and Armenia.

TEPHROMANTIA, τεφρομαντεια, in *Antiquity*, a species of divination, performed with ashes; for which see Potter, Archæol. Græc. tom. i. p. 353.

TEPHROSIA, in *Botany*, from τεφρος, ash-coloured, in allusion probably to the hoary aspect of the herbage.—“Perf. Syn. v. 2. 329.” Pursh 489. (Erebinthus; Mitchell in Ephem. Nat. Curios. v. 8. 210?)—Clas and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, deeply divided into five straight, awl-shaped teeth; the upper ones rather the shortest; the lowest rather longer than the rest. Cor. papilionaceous. Standard recurved, large, roundish-ovate. Wings half-ovate, obtuse, straight, rather shorter than the standard. Keel broad, rounded, gibbous, compressed, the length of the wings. Stam. Filaments ten, all firmly united along the middle into a membranous tube; the tenth separate at the base, and in its upper half; all capillary and distinct at the extremity, somewhat unequal in length; anthers terminal, uniform, ovate-oblong. Pist. Germen sessile, oblong, compressed, very hairy; style awl-shaped, angular, ascending, hairy along the back; stigma simple, recurved, slightly hairy. Peric. Legume oblong, compressed, hairy, somewhat falcate or ascending, of two valves and one cell. Seeds several, compressed, kidney-shaped, rather angular, slightly separated from each other by thin, imperfect, membranous partitions.

Ess. Ch. Calyx with awl-shaped, nearly equal, teeth. Stamens all connected. Legume compressed, rather coriaceous, of one cell, with many seeds. Stigma acute.

Obs. We have taken our characters from one certain species, *T. virginiana*, comparing it with authentic original specimens of Mitchell's *Erebinthus*, which Linnæus thought the very same species, but in this he was certainly mistaken. It appears to be Mr. Pursh's third species, *T. hispida*; and as far as we can judge, from specimens that will not admit of dissection, and from Mitchell's description, it is most probably of the same genus, for Mitchell might overlook the partial union of the stamens, even supposing that character to exist in his plant. If we were certain of this, his name ought, by every right, to be preferred to the more modern one of Pursh. (See EREBINTHUS.) The genus moreover is improperly placed in the sixth section of *Diadelphia*, while its essential character indicates that it belongs to the first.

1. *T. virginiana*. Virginian Grey-Vetch. Pursh n. 1. (Galega virginiana; Linn. Sp. Pl. 1062, excluding Hort. Cliff. and Mitchell's synonyms. Willd. Sp. Pl. v. 3. 1244. Ait. Hort. Kew. v. 4. 355. Cicer astragaloides (fortè) virginianum, hirsute pubescens, floribus amplius subrubentibus; Pluk. Phyt. t. 23. f. 2.)—Erect, hoary, and

and shaggy. Leaflets numerous, oval-oblong. Cluster terminal, many-flowered.—In dry sandy woods, from Canada to Florida, flowering in June and July. *Root* perennial. *Plant* about a foot high. *Flowers* very handsome, rose-coloured and yellowish-white. *Pursh.* The stem is simple, leafy, angular, brown, clothed with hoary pubescence. *Leaves* alternate, nearly sessile, pinnate, of from 17 to 21, not quite opposite, entire leaflets, each about an inch long, hairy on both sides, tipped with a minute point. *Cluster* solitary, various in length, composed of numerous large flowers, not unlike those of a Lupine. *Calyx* densely hairy. *Legume* an inch and a half long, pointed, linear, hairy, somewhat undulated, and a little curved upward, tumid where the seeds are lodged. Miller appears to have cultivated this plant in 1765. We have never seen a living specimen. That we have here described was sent by Kalm to Linnæus. The legumes came from Jacquin's herbarium.

2. *T. chrysophylla.* Golden-leaved Grey-Vetch. *Pursh* n. 2. (*Galega villosa*; *Michaux Boreal-Amer.* v. 2. 67? *Pursh.*)—Prostrate, downy. Leaflets five, somewhat wedge-shaped, very obtuse. Flower-stalks opposite to the leaves. Legume nearly straight.—Gathered in Georgia by Mr. Enslin, flowering in July and August. Perennial. Leaflets wedged-shaped-obovate; smooth above; silky at the back. Stalks elongated, bearing about three purple flowers. The singular circumstance of the nearly sessile leaves gives it the appearance of a trifoliolate plant, the lower pair of leaflets resembling *stipulas*. *Michaux's* synonym is rendered doubtful by his not mentioning the small number of leaflets, one of the most striking characters. *Pursh.*

3. *T. hispida.* Hispid Grey-Vetch. *Pursh* n. 3. (*Galega hispida*; *Michaux Boreal-Amer.* v. 2. 68. *G?* *Spicata*; *Walt. Carol.* 188. *Erebinthus*; *Mitch.* as above. *Clitoria*, n. 3; *Linn. Hort. Cliff.* 498, excluding the very erroneous reference to *Burm.*)—Slender, diffuse, downy. Leaflets numerous, oblong-elliptical, abrupt, pointed. Flower-stalks opposite to the leaves. Legume falcate, hispid.—In pine woods and on slate hills, from Virginia to Georgia. Perennial, flowering from July to September. Leaflets 13 or 15. Stalks elongated, bearing from three to five pale-red flowers. *Pursh.* Every part of this description answers to the original specimens of *Mitchell's* plant, but he, as well as *Linnæus*, speaks of the tenth stamen as being really separate from the rest. We cannot from our specimens determine this point. The stems are long, branched, trailing, round, and hairy. Leaflets with strong oblique transverse veins; sometimes smooth above; always silky beneath; their length about an inch. Bractees lanceolate. Calyx very bristly. Perhaps the union of the tenth stamen to the rest, which is not in the usual mode continued quite to the base, even in *T. virginiana*, may exist less, or not at all, in the species before us, and yet the plants may together constitute one natural genus.

TEPID, in *Natural History*, a term used by writers on mineral waters, to express such of them as have a less sensible cold than common water.

They distinguish all the medicinal springs into three kinds; the hot, the tepid, and the cold: but the middle term might easily be misunderstood to mean a great deal more than they express by it: all that have what can be called the least sensible warmth, are called hot; and the tepid are distinguished from the absolutely cold, only by their being less cold.

Some of this class of mineral waters, and some few also of the cold ones, have a sharpish vinous taste, which is never observed in any of the hot ones. This taste is lost on giving the waters the slightest heat, and is therefore very

difficult to be guessed at as to its origin. It is not only found in the aluminous and vitriolate waters, but also in those which are manifestly nitrous, and which abound in sulphureous salts, quite different in their nature from acids. It is therefore an additional somewhat, quite distinct from the saline properties of the fluid, and as easily connected with one kind of that as with the others.

The cause of heat in the mineral waters remains yet wholly unknown, notwithstanding all that has been written concerning it. It is hard to believe, that there are continual subterranean fires near enough the surface, to give a heat that preserves itself in so great a degree to the very place of their eruptions; and it is equally hard to conceive, that there can be beds of fermenting mineral matters, sufficient in quantity and force to have given the same degree of heat to waters for so many ages, as some of our hot springs are known to have subsisted. *Duclos's Exam. des Eaux Miner.*

TEPIDARIUM, among the Romans, a tepid or blood-warm bath, which was joined to the cold and hot baths, and was a medium between the two; so that if any person wanted to go from the hot to the cold bath, or vice versa, he always took the tepid bath in his way.

TEPIQUE, in *Geography*, a town of Mexico, in the province of Xalisco; 5 miles N. of Xalisco.

TEPIRU, a town of South America, in the province of Tucuman; 18 miles N.W. of St. Yago del Estero.

TEPKAS, a Russian settlement in North America, on the east side of Beering's strait. N. lat. 66°. E. long. 112° 4'.

TEPLITZ, a town of Bohemia, in the circle of Leitmeritz, celebrated for its warm baths, discovered in 762; 14 miles W.N.W. of Leitmeritz.—Also, a town of Croatia; 8 miles S. of Varasdin.

TEPLOW, GREGORY NICOLAICUITSCH, in *Biography*, a Russian writer, educated in a seminary at Novogorod, where he distinguished himself by a Latin translation of prince Cantemir's Satires, and a work on the geography of Russia, neither of which was ever printed. In 1740 he was employed in the Academy of Sciences, and in forming a catalogue of objects contained in the Cabinet of Natural History. He thus acquired a taste for that science, and particularly for botany; in consequence of which he was made an adjunct of the Society in 1741, and in the following year delivered lectures on moral philosophy, that were much approved. The empress Elizabeth appointed him tutor and travelling companion to her favourite, count Rasumofsky, who, on his return from his travels in 1746, was made president of the Academy of Sciences. Teplov then became an honorary member, directed the institution in the name of the president, and drew up rules for its better regulation. At the time of the empress's death he was a counsellor of state; but as he was an enemy to Peter III., he was arrested: afterwards he was restored to favour; nevertheless, two months after his being made a member of the council of state, it was discovered that he had joined in a conspiracy to dethrone that unfortunate prince. After the deposition of Peter, he published manifestations, in order to render him odious, and, as *Busching* says, was the principal agent in putting him to death. For this service he is said to have received a reward of 20,000 rubles. The empress afterwards made him a privy-counsellor and member of the senate, and honoured him with the orders of Alexander Newsky and St. Ann. He died in March 1779; and his works, in the Russian language, are, "A General View of Philosophy;" "Instructions to his Son;" "A Collection of Songs, with Melodies for three Voices;" "Instructions for

for the Cultivation of foreign Tobacco, in Lesser Russia," distributed by order of the empress through that province, in 1763. Gen. Biog.

TEPOTI, in *Geography*, a river of Paraguay, which runs into the Paraguay.

TEPPELWODA. See TOPPLISWODA.

TEPTERE, a name originally Tartarian, and signifying a man who cannot pay his taxes, given by the Russians to a peculiar tribe formed of Finns and Tartars in the middle of the 16th century, during the dissolution of the Khazan-Tartarian empire. They established themselves at first in that part of the Ural mountains, which belongs to the government of Ufa. At present they are so much intermingled, that their origin is scarcely discernible. They are found to increase in number at every succeeding census. In the year 1762, about 34,000 of them paid the imposts.

TEPTON, in *Geography*, a town of Thibet; 30 miles N.W. of Srigatchee.

TEPWIA, a town on the W. coast of the island of Celebes. S. lat. $1^{\circ} 4'$. E. long. $119^{\circ} 10'$.

TEQUENDAMA, a cataract near Bogota, the capital of New Granada (see BOGOTA), which, according to Bouguer, is one of the highest in the world, being 200 or 300 fathoms in height, and its fall vertical. Its real height is probably about 1320 feet. The river Funza, which is here very considerable, passes along a narrow channel, on a high table land, and is poured as from the spout of a vase, in one arch of the enormous height above specified, the noise being heard at the distance of seven leagues. This fall is received in a vast cauldron of more than a league in circumference; and the quantity of water, and violence of its descent, form a continual mass of clouds, which renders it scarcely visible in the evening; but in the morning it is more striking, being decorated with numerous rainbows according to the position of the spectator. The vast rocks which form the cauldron also excite admiration, being as regular and polished as if cut with a chisel: the surrounding heights are covered with trees, shrubs, and flowery plants, while the splendid appearance of some of the birds, and the music of others, render the cataract of Tequendama alike sublime and beautiful.

TEQUEPA, a town of Mexico, in the province of Mechoacan, on a river near the Pacific ocean; 80 miles S.E. of Zacatula. N. lat. $17^{\circ} 50'$. W. long. $102^{\circ} 26'$.

TEQUERY BAY, a bay on the south-east coast of Cuba, near Cape Cruz.

TEQUIA, a town of New Grenada; 32 miles S.W. of Pamplona.

TEQUIXQUIACATZANATL, in *Ornithology*. See GRACULA *Quiscalca*.

TER, in *Geography*, a river of Spain, which rises in the county of Cerdagne, and runs into the Mediterranean, about 20 miles E. of Gerona.

TERA, a small river of Spain, which runs into the Orbea, in the province of Leon.

TERACE, in *Rural Economy*, a term provincially applied to a coarse hair sieve, for separating the inferior flour from the bran.

TERAIN, in *Geography*, a river of France, which runs into the Oise, near Creil.

TERAKACO, a peninsula on the east coast of New Zealand, of which Cape Table forms the eastern point.

TERAMNUS, in *Botany*, so called by Browne, apparently in allusion to its delicately-shaped legume, *τεραμνίτης* being used particularly to express the tenderness of eatable pulse: *ατεραμνός* was a weed hostile to leguminous plants.—Browne Jam. 290. Swartz Prodr. 105. Ind. Occ. 1238.

t. 25. Schreb. 489. Willd. Sp. Pl. v. 3. 971. Mart. Mill. Dict. v. 4.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped, permanent; its upper lip rather the largest, divided; lower three-cleft; all the teeth acute, erect, converging. *Cor.* papilionaceous. Standard inversely heart-shaped, spreading, somewhat deflexed. Wings nearly as long, erect, approximated, rounded at the extremity. Keel very small, concealed in the calyx between the bases of the wings, and covering the stamens, separable into two petals. *Stam.* Filaments ten, all united in their lower part into one set; only five of them perfect, the five intermediate ones being minute, without anthers, and shorter; anthers five, roundish. *Pist.* Germen cylindrical, slender, downy; style none; stigma capitate, roundish. *Peric.* Legume linear, bordered, compressed, with numerous constrictions. *Seeds* several, roundish, compressed, abrupt at the summit.

Ess. Ch. Keel minute, concealed in the calyx. Stamens all connected; the five alternate ones without anthers. Stigma sessile, capitate. Calyx two-lipped. Legume linear, with many seeds.

1. *T. volubilis*. Smaller Teramnus. Swartz Ind. Occ. 1241. t. 25. Willd. n. 1, excluding all the synonyms.—Leaflets ovato-lanceolate, downy beneath.—Native of rather moist bushy alpine places, in the southern part of Jamaica. The stem is herbaceous, or slightly woody at the base only, from two to four feet high, twining, slender, triangular, downy, simple or divided. Leaves alternate, distant, stalked, each of three leaflets, mostly obtuse with a small point, entire, ribbed and veiny, smooth and bright-green above; downy beneath; sometimes accompanied by a pair of smaller ones at the base. Their common footstalk is about an inch long, channelled, downy, with a pair of minute linear stipulas at the base. Clusters axillary, slender, simple, longer than the leaves, of several small reddish-blue flowers, in distant couples, on short partial stalks. Legume an inch long, slender, hairy, its point finally hooked; the valves spiral after bursting.

2. *T. uncinatus*. Great Hooked Teramnus. Swartz Ind. Occ. 1239. Willd. n. 2. (T. n. 1; Browne Jam. 290. Dolichos uncinatus; Linn. Sp. Pl. 1019. Phaseolus hirsutus, siliquis rectis et aduncis; Plum. Ic. 215. t. 221. Ph. sylvestris minor, flore minimo, siliquis longis teretibus albâ lanugine hirsutis; Sloane Jam. v. 1. 182.)—Leaflets oblong; silky beneath; hairy above.—Native of dry bushy places, in various parts of Jamaica. The root is long and slender. Stem herbaceous, subdivided, twining, slender, triangular, its angles hairy and somewhat bordered; the base woody. Leaflets one and a half or two inches long; their common stalk an inch, or inch and a half. Stipulas small, downy, deciduous. Clusters axillary, stalked, often a span long, twice the length of the leaves, many-flowered. Flowers in distant pairs, small, reddish. Legume two inches long, straight, narrow, compressed, hairy, ending in a bluntish hooked point.

TERAMO, in *Geography*, a town of Naples, in Abruzzo Ultra; the see of a bishop, immediately under the pope; 22 miles N.N.E. of Aquila. N. lat. $42^{\circ} 37'$. E. long. $13^{\circ} 49'$.

TERANE, a town of Egypt, on the west branch of the Nile; 18 miles N.W. of Cairo. N. lat. $30^{\circ} 30'$. E. long. $30^{\circ} 45'$.

TERANO, a town of Naples, in Calabria Citra; 3 miles W. of Bisignano.

TERASARSUK, a town of East Greenland. N. lat. $59^{\circ} 55'$. W. long. 43° .

TERASPURG, a town of Austria; 2 miles N. of Egenburg.

TERATOSCOPIA, formed of *τερας*, prodigy, and *σκοπεω*, I consider, a kind of divination by the appearance and view of monsters, prodigies, spectres, and phantoms.

TERBEDH, in the *Materia Medica*, a name given by Avicenna to the *turbith*, a purging drug, mentioned by all the authors of his time; but, in general, in a very confused manner.

Garcias tells us, that the Indians use it to purge phlegm, and that they add ginger to it by way of corrective; and Avicenna says the same thing of its use in his time.

TERBURGH, **GERARD**, in *Biography*, a painter of domestic scenes of exquisite skill, was born at Zwoell, in the province of Overyssele, in 1608, the son of a painter little known, from whom he received the rudiments of the art. He began his career as a painter of portraits in small, and had acquired considerable reputation, when he determined upon travelling through Germany and Italy. Unengaged by the sublimer beauties of art which the latter country offered to his view, he never changed his style, but went thence to Paris to practise it; and there met with considerable success. From thence he returned to Holland, and was highly appreciated, and fully employed. He attended the congress assembled at Munster in 1648, for the negotiation of the treaty of peace, and there painted his celebrated picture containing portraits of the plenipotentiaries and principal personages assembled on that occasion, which is regarded as his master-piece; and of which there is a print by Suyderhoef. While engaged upon this work, he was invited by count Pigorando, the Spanish ambassador at the congress, to visit Spain, and went there in consequence; where he was most favourably received, and much employed. The king conferred upon him the order of knighthood, and rewarded him munificently for the pictures he painted. Besides portraits, which constituted the principal part of his practice, he frequently painted conversations, musical parties, ladies at their toilettes, and domestic subjects, which he executed with a free, but rather a heavy pencil, not equal to the brilliancy of Metz and Netscher, but nevertheless exceedingly meritorious and agreeable; particularly in the close imitations of his draperies. He died in 1681, at Deventer, where he settled on his return from Spain.

TERCERA, or **TERCEIRA**, in *Geography*, one of the Azores islands, supposed to have derived its name from its standing the third in this cluster of islands in point of situation, though the first in dignity, as appears from a number of circumstances, and particularly from its communicating its name to the rest. This island is computed at 54 miles in circumference, and about 25 miles in length, by 15 in medial breadth. Its figure is almost circular, the coasts high, and so surrounded with craggy rocks, that it is deemed impregnable; every accessible part on the coast being defended by strong forts, heavy cannon, and a numerous and regular garrison. The only tolerable port in the whole island is the harbour of Angra. The island of Tercera is fertile, pleasant, and healthy: the very rocks, which elsewhere are dry and barren, produce here excellent vines, though not equal to those raised in the Canaries and Madeira. The land yields large crops of wheat and other grain, pasture for cattle, and a prodigious variety of lemons, oranges, and all those fruits peculiar to hot and cold climates, which are observed to be propagated to the greatest advantage in temperate countries. Besides Angra, there are several other towns and large villages in Tercera, with a number of forts and garrisons, under the direction of the governor, who has the

power of filling up all vacancies that happen among the military officers. N. lat. 38° 45'. W. long. 27° 6'.

TERCERA, a small island in the Atlantic, near the coast of Sierra Leone.

TERCERO, a river of South America, which rises in Tucuman, and joins the Salado on the borders of Paraguay.

TERCHIZ, or **TERSHIZ**. See **TURSHISH**.

TER-CHOOUZ, in *Ornithology*. See **UPUPA Epops**.

TERDINA, in the *Materia Medica*, a name by which Paracelsus, and some other authors, have called the great garden-valerian. Ger. Emac. Ind. 2.

TERDOPIO, in *Geography*, a river of Italy, which runs into the Po, 12 miles E.S.E. of Lumello.

TEREBELLA, in *Natural History*, a genus of the Mollusca order of Vermes; the characters of which are, the body oblong, creeping, naked, furnished with branchiæ at the sides, more frequently in the tube; the mouth labiated, toothless, and projecting a clavated proboscis; the tentacula or feelers about the mouth numerous, capillary, and ciliated. Gmelin enumerates eleven

Species.

CIRRATA. Round, body with triple lateral pencils. Found in the sandy bottom of the Iceland sea.

LAPIDARIA. With eight cirri at the anterior parts of the body, about the mouth four. Found in the Mediterranean sea, within the clefts of rocks.

CONCHILEGA. Whitish, with numerous filiform cirri at the mouth, the upper longest; the branchiæ very red. Found in the sea washing the coast of Holland.

COMPLANATA. Depressed, mouth with four cirri; the lateral pencil-bearing warts of the body arranged on both sides in a two-fold series.

CARUNCULATA. Depressed-quadrangular, with a four-fold series of ventral pencils, and no cirri. Found in the American and Indian seas.

ROSTRATA. Tetraedrous, with a quadruple series of pencils from the body, and palate elongated. Found in the Indian sea.

FLAVA. Depressed, with thirty-seven branchiæ on both sides, and bifurcated tail. Found in the Indian sea.

RUBRA. Red, depressed; tail terminating with two cirri; the head with two horny moveable jaws. Found in the sea surrounding the islands of Zealand.

APHRODITOIS. Round, gradually attenuated backwards, below somewhat depressed with an obsolete furrow; no branchiæ in the eight first segments, in the following three simple, in the last sensibly greater, one being turned, pinnated. Found in the Indian sea.

BICORNIS. With a simple terminal two-horned disc of the proboscis. Found in the America ocean.

STELLATA. With a perfoliated triple disc of the proboscis; the anterior armed with a truncated horn, radiated with prickles. Found in the American ocean.

TEREBELLA, (dim. of *terebra*,) in *Surgery*, a trepan, or circular saw, for removing portions of the skull.

TEREBIA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, E. of the sources of the Tigris. Ptolemy.

TEREBINTACEÆ, in *Botany*, the 94th order in Jussieu's system, the 12th of his 14th class, so denominated from the genus for which he chooses to retain the old name of *Terebinthus*, but which is the *Pistacia* of Linnæus. Many of the plants of this order abound in an essential oil of the nature of turpentine, or something like it. The characters are as follow.

Calyx

Calyx of one leaf, inferior, with a definite number of segments. *Petals* definite in number, (rarely wanting,) inserted into the lower part of the calyx, alternately with its segments, with which they agree in number. *Stamens* either the same number, alternate with the petals, or twice as many, inserted into the same spot. *Germen* superior, either simple, or more than one, of a determinate number. When the germen is single, the *style* is solitary, (rarely deficient,) with a simple or a divided *stigma*; when there are several germens, the stigmas equal them in number. *Fruit* either capsular, a berry, or a drupa, of one or more single-seeded cells. Where there are several germens, there are as many styles, or simple stigmas; and the same number of distinct single-seeded capsules. The *seeds* are generally lodged in a bony nut. The *corculum* is without an *albumen*, its radicle lateral, and reflexed upon the lobes. *Stem* arborescent or shrubby. *Leaves* alternate, without *stipulas*, either simple, or ternate, or pinnate with an odd leaflet.

Section 1. *Germen simple. Fruit of one cell, with a solitary seed.*

This comprises *Cassivium* of Jussieu and Lamarck, which is the Linnæan *Anacardium*; *Anacardium* of the same authors, which is *Semecarpus* of Linnæus; *Mangifera*; *Connarus*; *Rhus*; and *Rourea* of Aublet, Schreber's *Robergia*.

Seçt. 2. *Germen simple. Fruit of many cells, some of which are occasionally abortive.*

Cneorum; *Rumphia*; *Coccoladia*; *Canarium*; *Icica* of Aublet; *Amyris*; *Toddalia*, which is *Crantzia* of Schreber, *Scopolia* of Sm. Plant. Ic. (see *SCOPOLIA*); *Scinus*; *Spathelia*; *Terebinthus* of Tournefort and Jussieu, the Linnæan *Pistacia*; *Bursera*; *Toluifera*; *Tapiria* of Aublet, which is Schreber's *Jonquetia*; *Poupartia* of Commerçon, perhaps not different from our *SPONDIAS Mangifera*; and *Spondias* itself, compose this section.

Seçt. 3. *Germen several. Fruit of many single-seeded capsules.*

Here are only three genera; *Simaba* of Aublet, which is Schreber's *Zwingeria*; *Alyanthus* of Desfontaines; and *Brucea* of L'Heritier.

Seçt. 4. *Genera akin to Terebintaceæ, but differing in being furnished with a fleshy albumen, which brings them near to RHAMNI*; see that article.

Cneffis of Jussieu, Lamarck Illustr. t. 387; *Fagara*; *Zanthoxylum*; and *Ptelea*.

Seçt. 5. *Genera akin to Terebintaceæ, and (like the true plants of this order) destitute of a fleshy albumen.*

Dodonæa; *Averrhoa*; and *Juglans*.

Jussieu announces an intention of dividing this order into *Cassivia*, true *Terebintaceæ*, and *Zanthoxyla*; the first having simple leaves, a single-seeded fruit, and an ascending radicle; the second generally pinnate or ternate foliage, a drupa with several single-seeded nuts, and a descending radicle; and the third pinnate or ternate foliage, mostly marked with pellucid dots; fruit of many cells or many capsules, each with solitary seeds; and a fleshy albumen surrounding a straight corculum. A fourth order would arise out of certain genera now intermixed with the rest, but not properly coming under any of the three just defined, being themselves perhaps entitled to lay the foundation of future orders, not as yet discovered.

TEREBINTHINA, in *Medicine, Natural History, &c.* See TURPENTINE.

TEREBINTHUS, in *Botany*, *τερεβινθος* of Dioscorides. See PISTACIA and TEREBINTACEÆ.

TEREBOTIN, a word used by Paracelsus for the common turpentine.

TEREBRA, from *τερεω*, to bore, a trepan, or trephine.

Also, an instrument called a perforator, such as is contained in the generality of cases of trephining instruments, and is used for making a hole, in which the centre pin of the trephine is to work.

TEREBRATULA, in *Natural History*, a name given by Mr. Lhuys and Gualtieri to some species of the smooth conchæ anomia, which have near the head of the shell a small hole, which looks as if bored by art. See *CONCHÆ Anomia*, and SHELLS.

TERECOL, in *Geography*, a town of Hindoostan, in Concan; 16 miles N.N.W. of Goa.

TEREDO, in *Natural History*, a genus of the Testacea order of Vermes, the characters of which are, that the animal is a terebella, with two hemispheric calcareous valves, cut off before, and two lanceolated; the shell is round, flexuous, and capable of penetrating wood. Gmelin reckons three

Species.

NAVALIS. The shell very slender, cylindric and smooth.

UTRICULUS. Shell solid, cylindric and undulated.

CLAVA. Shell clavated at one end, the other curved, narrower, obtuse, and perforated in the middle.

The head of the *Teredo navalis*, called by Linnæus *calamitas navium*, is well prepared by nature for the hard offices it is to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech; by which it pierces wood, as that animal does the skin: a little above this it has two horns, which seem a kind of continuation of the shell; the neck is as strongly provided for the service of the creature as the head, being furnished with several strong muscles; the rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and by means of the microscope, several other very remarkable particulars become visible there.

This creature is wonderfully minute when newly excluded from the egg, and at its utmost bigness is a foot long; three or four inches are however its more frequent length.

When the bottom of a vessel, or any other piece of wood constantly under water, is inhabited and injured by ever so great a number of these worms, there is no sign of the damage to be perceived on the surface, nor are the creatures visible till the outer part of the wood is cut or broken away; then their shelly habitations come in sight: these lie so near the surface, however, as to have an easy communication with the water, and there is a multitude of little perforations in the very surface through which the inhabitant insects throw out the extremities of their little shelly horns; these are of a reddish colour, and may be distinguished by an accurate observer in form of so many red prominent points; they all are retracted on the least touch, and are thrown out again as soon as all is quiet. From these points, or the small apertures which give them a way out, are the cells of the teredines to be traced. They are composed of a pearly or shelly matter, which forms a long tube with various windings and turnings, which mark the abode of the creature; but which usually neither adheres to the body of the animal nor to the wood. These cases or tubes are always more or less loose in the wood, and there is ever a large space within them, for the body of the animal to be surrounded every way with water. They are very smooth on the inner surface, and somewhat rougher without; and are much harder and firmer in the cells of the older and larger animals than in those of the young ones.

These shelly tubes are composed of several rings, or an-

nular parts; but these differ greatly in their length. There is an evident care in these creatures, never to injure one another's habitations; by this means each tubule or case is preserved entire, and in such pieces of wood as have been found eaten by them into a sort of honey-comb, there never is seen a passage or communication between any two of the tubules, though the woody matter between them often is not thicker than a piece of writing-paper.

The vast increase of these animals, and their shelly tubules, naturally lead to a consideration of the manner of their generation; and when we consider that each of these creatures is, from the time when it is produced from the egg, immediately lodged in a cell, in which it lives without the least possibility of getting into that of another animal of its own kind, or receiving one of them into its own, it is not easy to account for the propagation of the species in the common way. This, however, is solved by an accurate anatomical observation of the animals themselves, since in every individual the parts of generation in both sexes, and both the semen and ovula are found. Each individual therefore evidently serves by itself for the propagation of the species; and this is probably very often the case in earth-worms, and other of the hermaphrodite animals. All the yet known kinds of these being soft-bodied; and probably, though they often meet one another, and copulate in pairs, yet when they have not opportunity, the parts copulate in the individual.

Eggs are found in great plenty in the bodies of these animals in June, and are discharged with the water into the sea, where the far greater part of them, doubtless, become food for other small marine animals; and the few that affix themselves to any piece of wood they are washed against, batch and get into its substance in the manner of their parents.

The kind of wood in which these worms are lodged, makes a great difference in the appearance of their cells, as they work much more speedily and successfully in some kinds than in others. The fir and alder are the two kinds they seem to eat with the greatest ease, and in which they grow to the greatest size. In the oak they seem to make but a very slow progress, and usually appear very small, and poorly nourished. The colour of their shelly tubules is often brown in this wood; which seems plainly owing to the effect of its juices.

Poisonous ointments are also found to be of some use in destroying them, on rubbing over the wood: some have thought that burning the surface was an effectual way of preserving them, but this has been found to be otherwise. The surest method of avoiding them in particular works, is the using of bitter or very solid woods; the first kind they are found never to touch, and in the other they make but slow progress. Mixtures of lime, sulphur, and colocynth, with pitch, for covering over the surfaces of boards, &c. have been found of some use.

It seems very evident, that boards and other pieces of wood have been subject to be eaten by these animals, from all times that we have any knowledge of; for the stone called *lapis syringoides* is evidently no other than wood thus eaten, petrified by long lying in the earth, together with the tubules of the worms. The masses of this with the grain of wood yet plain in them, are common in many places among sea-shells, and other marine remains at great depths, and have evidently been brought thither in very distant times, and before those changes were made in the surface of the earth of which we have no accounts in our earliest histories. Sellii Hist. Natur. *Teredinis*.

TEREDON, in *Ancient Geography*, a town of Asia, in

Babylonia, on an island which was formed by the Tigris at its mouth. (Ptol.) Dionysius Periegetes places the town of Teredon at the mouth of the Euphrates.

TEREK, in *Geography*, a mountain of Asia, between Great and Little Bucharia.

TEREK, one of the rivers that fall into the Caspian sea. It originates in the Caucasian mountains, runs at first towards the W. and S., but turns afterwards entirely to the E. and in about N. lat. 44°, and E. long. 65°, discharges itself into the Caspian. It takes up in its course the Bakfan, the Malka, and the Soonsha, among many other mountain-brooks and rivers. Its source lies properly in the Snow-mountains of Caucasus, on the highest partition-ridges of the frontiers of Georgia. It is rapid in its course; and, in the months of July and August, when the snow melts, swells to the height of eight or ten feet above its usual level in autumn, winter, and spring; overflowing its banks, and inundating the adjacent country, forming for itself new beds, and choking the old with sand. In its lower course, as far as Kitzliar, it is almost entirely unaccompanied by woods; farther up, to Starogladka, by a few; and thence upwards, its banks are richly garnished with forests, particularly of oaks, wild fruit-trees, and a variety of others. It does not freeze over every year, though in winter it abounds with driving ice. In this season its water is tolerably clear, which at other times, above Kitzliar, is turbid, with earthy particles; but when taken up, it soon becomes clear, and is then bright, well-tasted, and of good quality. Below Kitzliar, the river has a less fall, and separates into several arms, in which the parted stream flows so gently, that it has time to deposit its earthy particles, which alternately fill up these arms; so that one or the other occasionally represents the main river. In the lower regions, on the shores of the Terek, are seen vineyards, mulberry and other fruit-trees, to which succeed salt-lakes, and springs of the same nature. Its bed is formed mostly of sand and clay. With regard to fish, the Terek, as well as all its collateral rivers, is poor. Yet there are caught in it sturgeon (*acipenser sturio*), beluga (*acipenser huso*), ferruga (*acipenser stellatus*, Pall.), plenty of salmon, fat-fish (*cyprinus thalcoides*), carp, barbel (*cyprinus barbatus*), shad, pike, sudak (*lucio perca*), perch (*perca fluviatilis*), leschtse (*cyprinus barba*), otters, beavers, tortoises, &c.

TEREK, in *Ornithology*. See *SCOLOPAX Cinerea*.

TERELLA, in *Geography*, a town of Naples, in the Molise; 4 miles N. of Molise.

TERENCE, PUBLIUS TERENTIUS, in *Biography*, a Latin writer of comedies, was born, as it is supposed, at Carthage about the year of Rome 560 (B.C. 194.) Being brought to Rome as a slave, when young, he was in the service of a person named Terentius, a senator, from whom he derived his name. The purity and politeness of his language evince his having enjoyed the benefit of a good Roman education. After his emancipation, he was honoured with the friendship of several Romans of rank, such as Scipio Africanus the younger, and the younger Lelius. His comedies were founded upon the Greek model, and translated, either wholly or in part, from the Greek. The first comedy which he is said to have brought upon the stage, was the "Andrio," represented in the year B.C. 166. But though this was the first of his comedies that was acted, it appears that it was not the first which he had written. The six comedies of Terence that are still extant were exhibited at Rome from the year B.C. 166 to 160. They were heard with great applause; the "Eunuchus" was repeated twice in the same day, and he is said to have received for it 8000 sesterces (about 64*l*.) Scipio and Lelius,

Lelius, as tradition reports, had a great part in the composition of Terence's comedies. Terence himself in a prologue seems tacitly to acknowledge the fact. But modern writers and critics, who have reasoned on this fact, think it very improbable. Generals and statesmen were not persons likely to possess the habit of dramatic composition, whatever previous hints or subsequent corrections they might furnish; and besides it is observed, that no writings more strongly indicate by their style and manner that they are the production of a single hand than those of Terence. After he had presented these comedies to the public he departed for Greece, and never returned to Rome. Some have accounted for this circumstance, by supposing that he perished by shipwreck; others affirm that he died in Greece, from the grief he experienced on account of the loss of his baggage and some new comedies, which he had composed, by an accident at sea.

The judgment of critics on the performances of Terence has been very different, though their real merit is said not to be of difficult estimation. It is generally allowed that he is defective in invention and originality of observation. This sufficiently appears from his having Greek manners and characters in all his plays. He was likewise a plagiarist, with regard to the sentiments, as well as to the plots and incidents of his pieces; but a very competent judge observes, "that he is justly entitled to the praise of judicious selection, happy disposition, and purity and neatness of language; and that, as a Latin writer, in a style of elegance of which there are so few examples, he was highly prized in his own times, and is invaluable in ours. Cicero, who speaks of him as a translator of Menander, applauds him as the only one who had expressed in the Latin language all the politeness and amenity of the original; and Cæsar, in some well-known lines, calls him 'the lover of pure diction;' and also by the epithet of the *halved Menander*; and his regret that Terence did not possess the *vis comica*, as well as the other excellencies of his model, points out his deficiencies." Of the numerous editions of Terence, the most esteemed are the following; viz. the "*Variorum*," Amst. and Lugd. Batav. 1686; "*Bentleii*," Cantab. 4to. 1726; "*Westerhovii*," Hag. C. 4to. 1726; "*Zeunii*," Lips. 8vo. 1774; "*Brunckii*," Basil. 4to. 1779. Voss. Poet. Lat. Gen. Biog.

TERENJABIN, in the *Materia Medica of the Ancient Arabians*, a word used to express a kind of manna called by some *manna massichina*, from its round globules resembling the drops of mastic, and by the physicians of many parts of the world at present, *Manna Persicum*; which see. See farther about this drug in Philof. Trans. N^o 472. vol. xliii. p. 87.

TERES LIGAMENTUM, in *Anatomy*, one of the ligaments of the hip-joint. See EXTREMITIES.

TERES Ligamentum Uteri. See GENERATION.

TERES Major and Minor, two muscles of the shoulder, so called, because their figure is somewhat rounded.

The *teres major* (scapulo-humerien, le grand rond) is elongated and flattened, placed at the lower and back part of the shoulder, and extending from the inferior angle of the scapula to the posterior edge of the bicipital groove of the humerus. The latissimus dorsi, the skin, and the long head of the triceps, cover it behind; in front, it is covered by the latissimus, the axillary vessels and plexus of nerves, the short head of the biceps, and the coraco-brachialis. Its upper edge corresponds first to the *teres minor*, then is separated from that muscle by the long head of the triceps, and lastly corresponds to the subscapularis, from which the circumflex vessel and nerve separate it. The lower edge, covered by

the skin, forms, with the latissimus, the border of the axilla. The inferior or external extremity of the muscle is fixed to the external surface of the inferior angle of the scapula, and to the neighbouring part of its lower edge: thence it ascends, passing obliquely outwards, retaining nearly an uniform breadth (about three fingers) throughout; and is attached to the posterior margin of the bicipital groove. The latter attachment takes place by means of a flattened tendon, about an inch broad, which corresponds in front to that of the latissimus dorsi. There is a small bursa mucosa between its posterior surface and the humerus. It lines the bicipital groove by some fibres, which meet those of the pectoralis major. Muscular fibres arise from the outer surface and inferior angle of the scapula, from the lower portion of the inferior costa, and from a septum between this muscle and the infraspinatus; and they terminate on the tendon just described. It carries the arm backwards; depresses it when it has been raised; rotates the humerus on its axis, so as to turn the arm inwards or forwards. In conjunction with the latissimus, and pectoralis major, it will fix the arm against the side. It will pull the scapula forwards or upwards to the arm, when that is fixed.

Teres minor (petit rond) is a small elongated muscle, lying at the posterior and under part of the shoulder, extending from the inferior edge of the scapula to the external tubercle of the humerus. Covered behind by the deltoid and skin, it covers in front the edge of the scapula, the infrascapular artery, the long head of the triceps, and the orbicular ligament of the shoulder-joint. Its upper edge is either continuous with the infraspinatus, so that they form but one muscle, or is separated from it by a cellular line. Towards the back part there is an aponeurotic septum between them. The lower edge is close to the *teres major* behind, but separated from it anteriorly by the long head of the triceps. The lower or posterior extremity is small and pointed, and begins its attachment to the scapula, just where that of the *teres major* ends, between the latter muscle and the infraspinatus: it passes obliquely upwards and outwards, fixed to the lower and outer edge of the scapula, and is inserted in the lower or back part of the great tubercle of the humerus. This insertion is effected by means of a tendon, closely connected to that of the infraspinatus, dispersing some of its fibres on the orbicular ligament, and receiving the fleshy fibres in all directions from the origin of the muscle. Its action has exactly the same effect with that of the *infraspinatus*; which see.

TERES Folium, in *Botany*. See LEAF.

TERESA, or THERESA, in *Biography*, a faint in the Roman Catholic church, was born, of a noble family, at Avila, in Old Castile, in March 1515. Her father, by reading the lives of saints to his family, inspired her, at an early age, with an enthusiastic fervour, which induced her to elope with one of her brothers, to seek martyrdoms among the Moors. When they were brought back, they indulged the same passion by constructing little hermitages in the garden, whither they retired to perform their exercises of devotion at twelve years of age. Teresa lost her mother, and was boarded in an Augustine convent, and this situation prevented her being seduced by the pleasures of the world, for which she began to indulge a propensity in consequence of reading romances; but for her farther security she took the veil in the Carmelite monastery of the Incarnation at Avila, in her twenty-second year. Her person was beautiful, and attracted the admiration and love of all who saw her; but her religious ideas, though tender and rapturous, were austere; and perceiving that the discipline of the house in which she resided was relaxed, she undertook a reform of the Carmelite order. After much opposition, she succeeded in establishing the

first monastery of the female reform at Avila, in 1562, and having extended her plan to the religious males of the order, she founded in 1568 the monastery of Dorvello, which was the origin of the more rigid, or barefooted, Carmelites. Her zeal and assiduity enabled her to found thirty religious houses of the reform, fourteen for men and sixteen for women; and after her death it extended through all the Catholic countries of Christendom. Teresa died at Alva in October 1582, in the 68th year of her age. She was canonized by Gregory XV. in 1621; and afterwards became the patron saint of Spain. See CARMELITES.

TERESA, in *Geography*, a town of Spain, in the province of Valencia; 10 miles N.W. of Segorbe.

TERESSA. See TERESSA.

TERETES, in *Horfes*, one of the three sorts of worms which infest the bodies of them, and which are very troublesome and injurious. See ASCARIDES, BOTS, and WORMS.

This sort of worm, which is found in horfes, resembles the common earth-worms in many respects, being only sharper at both ends, callous towards the middle, and they do not contract or dilate themselves so easily. Some of these, which have been seen to come from horfes, hinder them from thriving till they are dislodged by proper remedies.

TERETRUM, in *Surgery*. See TEREBRA.

TERFEZ, in *Natural History*, the name given by the Africans to the truffles found in the deserts of Numidia, and other places in that part of the world, in great abundance.

These are much more delicately tasted than the European truffles, and are white on the outside. They are called by some of the Africans *kema*, and by the Arabian writers *cantha* and *camabe*.

TERFOWA, in *Geography*, a town of Africa, in the kingdom of Tunis; 120 miles S. of Tunis.

TERFOWY, a town of Nubia; 150 miles S. of Syene. N. lat. $21^{\circ} 40'$. E. long. $34^{\circ} 5'$.

TERGA, a town of Morocco, on the Morbeya; 90 miles N. of Morocco.

TERGA. See HAIR.

TERGARRY, a town of Hindoostan, in Bednore; 14 miles S.E. of Simogu.

TERGAZA, in *Ancient Geography*, a town of Africa, which was one of those which Manlius took possession of in the third Punic war, and which he pillaged.

TERGESTE. See TRIESTE.

TERGESTICUS SINUS, a gulf of Italy, on the coast of the Adriatic sea. It took its name from the town Tergeste, which was situated there.

TERGIFOETOUS PLANTS, such as bear their seeds on the backside of their leaves: such are the capillaries. See CAPILLARY.

TERGIL, in *Geography*, a town of Asiatic Turkey, in the province of Erzerum; 30 miles E. of Palu.

TERGIS, in *Ancient Geography*, a town of Africa, in Libya, on the confines of Ethiopia.

TERGISONUS, a river of Italy, in Venetia, N. of the river Padus.

TER-GOUD, or TER-GOUW, in *Geography*. See GOUD.

TERGOVITZ, or TERGOVISTA, a town and capital of Walachia, where the waiwode has a palace; 64 miles S.E. of Hermenstadt. N. lat. $45^{\circ} 3'$. E. long. $25^{\circ} 29'$.

TERHALTEN, a small island near the coast of Terra del Fuego. S. lat. $55^{\circ} 20'$.

TERHEY, a town of Holland; 10 miles W. of Delft.

TERIDATA, in *Ancient Geography*, a town of Asia, in Mesopotamia, on the banks of the Euphrates. Ptolemy.

TERINA, a town of Italy, upon the western coast of

Bratium, and in the northern part of the gulf Hipponium.— Also, a town of Asia, situated in the mountains W. of Moxouné.

TERIUM, a town of Macedonia, in Pieria.

TERKAT, in *Geography*, a town of Asiatic Turkey, in the government of Sivas; 20 miles N.W. of Tocat.

TERKELA, a river of Africa, which joins the Tafilet, 20 miles S. of Togda.

TERKI. See TEREK.

TERKI. See TURKIN.

TERKIRI, a lake of Thibet, about 80 miles long and 25 broad. N. lat. 32° . E. long. $91^{\circ} 14'$.

TERKUL, a river of Russia, which runs into the Ural, at Uralsk, in the government of Caucasus.

TERLIZZI, a town of Naples, in the province of Bari; 7 miles S.E. of Trani.

TERLON, a river of France, which runs into the Sambre, about 3 miles below Landrecy.

TERM, TERMINUS, the extreme of any thing, or that which bounds and limits its extent. See EXTREME.

TERM, in *Geometry*, is sometimes used for a point, sometimes for a line, &c. A line is the term of a superficies, and a superficies of a solid.

This is what the schools call *terminus quantitatis*.

TERM, in *Law*, signifies a boundary, or limitation of time, or estate.

In this sense we say, a lease for term of life, for term of years, &c.

TERMS, *Termes*, *Termini*, in *Architecture*, denote a kind of statues, or columns, adorned at top with the figure of a man's, woman's, or satyr's head, as a capital; and the lower part ending in a kind of sheath, or scabbard. See HERMES.

Some write the word *thermes*, from *Hermes*, a name the Greeks gave the god Mercury; whose statue, made after this manner, was placed in several of the cross ways in the city of Athens, &c. Others bring the etymology of the word from the Roman god Terminus, the protector of landmarks; whose statue (made without hands or feet, that he might not change his place) was used to be planted at the bounds of lands, to separate them.

Terms are sometimes used as consoles, and sustain entablatures; and sometimes as statues, to adorn gardens. Of these termini, the architects make great variety; viz. *angelic*, *rustic*, *marine*, *double*, in *buft*, &c.

TERMS, *Miliary*, *termini miliares*, among the ancient Greeks, were the heads of certain divinities, placed on square land-marks of stone, or on a kind of sheath, to mark the several stadia, &c. in the roads. These are what Plautus calls *lares viales*.

They were usually dedicated to Mercury, whom the Greeks believed to preside over the highways.

Some of them were represented with four heads, such as we still see in Rome, at the end of the Fabrician bridge; which is hence called *ponte di quattro capi*. It is known that Mercury was thus represented, and also called by the Latins *Mercurius quadrifrons*; as being supposed the first who invented the use of letters, music, wrestling, and geometry. See HERMES.

TERMS are also used for the several times or seasons of the year, in which the tribunals, or courts of judicature, are open to all who think fit to complain of wrong, or to seek their rights by due course of law, or action; and during which the courts in Westminster-hall sit and give judgment. But the high court of parliament, the chancery, and inferior courts, do not observe the terms; only the courts of king's bench, common pleas, and exchequer, which are the highest courts

courts at common law. In contradistinction to these, the rest of the year is called *vacation*.

Of these terms there are four in every year, during which time matters of justice are dispatched.

Hilary term, which, at London, begins the 23d of January, or if that be Sunday, the next day after; and ends the 12th of February following.

Easter term, which begins the Wednesday fortnight after Easter-day, and ends the Monday next after Ascension-day.

Trinity term, beginning the Friday next after Trinity-Sunday, and ending the Wednesday fortnight after.

Michaelmas term, which begins the 6th of November, and ends the 28th of November following.

Each of these terms has also their *returns*; which see.

These terms are supposed by Mr. Selden to have been instituted by William the Conqueror; but sir H. Spelman hath shewn, that they were gradually formed from the canonical constitutions of the church; being no other than those leisure seasons of the year, which were not occupied by the great festivals or fasts, or which were not liable to the general avocations of rural business. Throughout all Christendom, in very early times, the whole year was one continued term for hearing and deciding of causes. For the Christian magistrates, in order to distinguish themselves from the Heathens, who were very superstitious in the observation of their *dies fasti* and *nefasti*, administered justice upon all days alike; till at length the church interposed, and exempted certain holy seasons from being profaned by the tumult of forensic litigations; as, particularly, the time of Advent and Christmas, which gave rise to the winter vacation; the time of Lent and Easter, which created that in the spring; the time of Pentecost, which produced the third; and the long vacation, between Midsummer and Michaelmas, which was allowed for the hay-time and harvest. All Sundays also, and some peculiar festivals, as the days of the Purification, Ascension, &c. were included in the same prohibition, which was established by a canon of the church, A.D. 517, and fortified by an imperial constitution of the younger Theodosius, comprised in the Theodosian code. Afterwards, when our own legal constitution was established, the commencement and duration of our law terms were appointed, with a view to these canonical prohibitions; and it was ordered by the laws of king Edward the Confessor, that from Advent to the octave of the Epiphany, from Septuagesima to the octave of Easter, from the Ascension to the octave of Pentecost, and from three in the afternoon of all Saturdays till Monday morning, the peace of God and holy church shall be kept throughout the whole kingdom.

And so extravagant was afterwards the regard paid to these holy times, that though the author of the Mirror mentions only one vacation of considerable length, containing the months of August and September, yet Britton says, that in the reign of king Edward I. no secular plea could be held, nor any man sworn on the Evangelists, in the time of Advent, Lent, Pentecost, harvest, and vintage, the days of the great litanies, and all solemn festivals. He adds, that the bishops and prelates granted dispensations for taking assizes and juries in some of these holy seasons, upon reasonable occasions; and soon after a general dispensation was established in parliament by stat. Westm. 1. 4 Edw. I. cap. 51, that assizes of novel disseisin, mort d'ancestor, and darrein presentment, should be taken in Advent, Septuagesima, and Lent, as well as inquests; at the special request of the king to the bishops. The portions of time that were not included within these prohibited seasons, fell naturally into a fourfold division; and from some festival, or saint's day that immediately preceded their commencement, were denominated the

terms of St. Hilary, of Easter, of the Holy Trinity, and of St. Michael: which terms have been since regulated and abbreviated by several acts of parliament; particularly Trinity term by stat. 32 Hen. VIII. c. 2. and Michaelmas term by stat. 16 Car. I. c. 6. and again by stat. 24 Geo. II. c. 38. Blackst. Com. vol. iii.

TERMS, Oxford. Hilary or Lent term begins January 14th, and ends the Saturday before Palm-Sunday. Easter term begins the tenth day after Easter, and ends the Thursday before Whitsunday. Trinity term begins the Wednesday after Trinity-Sunday, and ends after the act, or 6th of July, sooner or later, as the vice-chancellor and convocation please. Michaelmas term begins October 10th, and ends December 17th.

TERMS, Cambridge. Lent term begins January 14th, and ends the Friday before Palm-Sunday. Easter term begins the Wednesday after Easter-week, and ends the week before Whitsunday. Trinity term begins the Wednesday after Trinity-Sunday, and ends the Friday after the commencement, or 2d of July. Michaelmas term begins October 10th, and ends December 16th.

TERMS, Scottish. In Scotland, Candlemas term begins January 23d, and ends February 12th. Whitsuntide term begins May 25th, and ends June 15th. Lammas term begins July 20th, and ends August 8th. Martinmas term begins November 3d, and ends November 29th.

TERMS, Irish. In Ireland the terms are the same as at London, except Michaelmas term, which begins October 13th, and adjourns to November 3d, and thence to the 6th.

TERM, in *Grammar*, denotes some word or expression in a language. See **WORD**.

The word *term*, *terminus*, is borrowed metaphorically, by the grammarians and philosophers, from the measurers or surveyors of lands: as a field is defined and distinguished by its *termini*, or limits, so is a thing or matter spoken of, by the word or term by which it is denoted.

TERM, in the *Arts*, or *Term of Art*, is a word which, besides the literal and popular meaning which it has, or may have, in common language, bears a farther and peculiar meaning in some art or science. See **ART**.

Or, a term is a word which has one or more meanings beside its grammatical one; or which has a peculiar force or import in the language of some particular science or art.

A word then becomes a term when its idea is rendered more complex, consists of more parts, and includes more special circumstances, on some occasions than others.

It is this greater complexness, this excess of constituent parts of the idea, that denominates it a term in the general. Farther, as the parts of the idea, signified by any word, are arbitrary; and as one may not only add new parts to those contained in the literal meaning, but also superadd others to them, alter them, extend them, and otherwise modify them at pleasure; hence the same word becomes a term of this or that art, or both, as the inventors or improvers of those arts have thought fit to adopt it for the common basis of certain ideas, and to modify and circumstantiate its meaning to the use of their respective arts. See **DEFINITION**.

TERMS, *abstract, complex, concrete, equivalent, equivocal, general, relative, synonymous, univocal*. See the adjectives.

TERM, in *Logic*. A proposition is said to consist of two terms, *i. e.* two principal and essential words, the *subject* and the *attribute*.

A syllogism consists of three terms, the *major*, *minor*, and *conclusion*. See **SYLLOGISM**.

TERMS of an Equation, in *Algebra*. See **EQUATION**.

TERMS of Proportion, in *Mathematics*, are such numbers, letters,

letters, or quantities, as are compared one with another. See PROPORTION.

TERMS, or *courses*, in *Medicine*, the menses, or women's monthly purgations.

TERMALY, in *Geography*, a town of Hindoostan, in Myfore; 15 miles N.E. of Anantpour.

TERMED, or TARMAD, a town of Grand Bucharia, at the union of two large rivers, whose united streams form the Jihon; the capital of a considerable district. In 1221, this town was besieged by Jenghis Khan, and, after eleven days, taken by assault: after which the conqueror put most of the inhabitants to the sword, and destroyed the town. It was rebuilt in the following century; 130 miles S. of Samarcand. N. lat. 37° 30'. E. long. 65° 48'.

TERMEH, or KARMILI, a river of Asiatic Turkey, which runs into the Black sea, 30 miles N.E. of Samfoun.

TERMERA, or TERMERIUM, in *Ancient Geography*, a free town of Asia Minor, in Caria.

TERMES, called *Tierme*, a town of Hither Spain, belonging to the Arevaci, S. of Numantium.

TERMES, in *Entomology*, a genus of the Aptera order of insects. Its characters are, that it has six legs formed for running; two eyes; setaceous antennæ, and a mouth with two jaws. According to Gmelin, the characters are, that the mouth has two horny jaws, with a horny, quadrifid lip, linear acute fringes, four equal filiform feelers, or palpi, antennæ (mostly) moniliform, and two eyes. Linnæus enumerates three, and Gmelin eight

Species.

FATALE. Above brown; thorax with three segments; wings pallid, and costa, or rib, testaceous. This is the destructor of Degeer, and *T. bellicosum* of Smeathman. It is found in the shady parts of the equinoctial regions of India and Africa. See the sequel of this article.

DESTRUCTOR. Above testaceous; head black; antennæ yellow. Found in the islands opposite to South America, Africa, and India.

ARDA. Black; abdomen with segments white at the apex; legs pallid. Found in the equinoctial parts of Africa.

MORDAX. Black; the segments of the abdomen white at the apex; legs black. Found in the equinoctial parts of Africa.

CAPENSE. Yellow, with hyaline wings; brown at the margin. Found in India and Southern Africa.

FATIDICUM. Abdomen ovate; mouth pallid; brown eyes; antennæ setaceous. Found in Europe, chiefly the southern part.

PULSATORIUM. Abdomen oblong; mouth red; eyes yellow; antennæ setaceous. Found in Europe and America.

DIVINATORIUM. Abdomen transversely fulcated; brown mouth, and black eyes. Chiefly found in books; very lively, irritable, and whitish.

It is observed, that the European species of termes are very small, compared with those of the warmer regions of Africa and America; and instead of being gregarious, as in those climates, are usually found single. Of these, the most known is the *T. pulfatorius* of Linnæus, a small insect of a whitish colour, and distinguished by Derham and some other naturalists, by the appellation of "*Pediculus pulfatorius*." During the months of summer it is common in houses, particularly in decayed wainscots, and is remarkable for emitting a long-continued sound, resembling the ticking of a watch; it is commonly met with in collections of dried plants, &c. to which it is very injurious. It cannot bear, on account of its tender frame, the slightest pressure, and it

is very quick in its motion. When magnified, the head appears large, the eyes very conspicuous, of a beautiful golden colour, and divided into innumerable hexagonal convexities; the antennæ long and setaceous; the palpi two in number, moderately long, and terminating in a large club-shaped top; the thorax rather narrow, and the abdomen obtusely oval; the thighs, or first joints of the legs, thick, the remaining ones slender, and the feet furnished with very small claws. The whole animal is beset with scattered hairs. This insect, according to the observations of Derham, when first hatched from the egg, is white, oval, and very small, exactly resembling a common mite; furnished with eight legs, and beset with long hairs. After a certain time it casts its skin, and appears in the form already described. Degeer has found on each side of the thorax the appearances of rudiments of wings, resembling a pair of oblong scales; and Dr. Shaw affirms, from his own observations, that some individuals of this species become winged at their full growth; the wings, four in number, being very large, of a slightly indistinct appearance, and variegated with blackish and brown clouds or spots. In the beginning of July this change takes place, and several insects may be seen with the wings half-grown; in a few days they gain their full size.

Dr. Derham is of opinion, that the ticking sound of these animals is analogous to the call of birds to their mates during the breeding season; and this opinion is very probable. The sound, says Dr. Shaw, as well as that produced by the "*Ptinus fatidicus*," or death-watch, seems to prove in a convincing manner, that insects possess the faculty of hearing, though this be denied by some naturalists.

Of the exotic termites, the most remarkable is the *T. bellicosus*. The animals of this species have lately been minutely described by Mr. Smeathman, from whose account the following particulars are extracted.

The termites, which have been taken notice of by various travellers in different parts of the torrid zone, and called by the name of white ants, resemble the ants in their manner of living, which is in communities, forming extraordinary nests in the surface of the ground, and various subterraneous passages, and also in their provident and diligent labour; but in both respects much surpass them. The termites are represented by Linnæus as the greatest calamity of both Indies, because of the havoc they make in all kinds of wooden buildings, utensils, and furniture, so that nothing but metal or stone can escape their destructive jaws.

Smeathman observes, that the insect in its perfect state has four wings without any sting, and should therefore be ranged under the *neuroptera*, and not under the *aptera* of the Linnæan system. The communities of termites consist of one male and one female, generally the parents of all the rest, and of three orders of insects, apparently of very different, though really of the same species. Those of the first order are the working insects, or labourers; the second comprehends the fighting insects, or soldiers, which do no labour; and the third are the winged ones, or perfect insects, which are male and female, and capable of propagation, but neither labour nor fight; the kings and queens belong to this order, and within a few weeks after they are elected and elevated to this rank, they migrate, and either establish new kingdoms, or perish within a day or two. The largest species, called *termes bellicosus*, is the best known on the coast of Africa; it erects immense buildings of well-tempered earth or clay, which are constructed with signal ingenuity: it does infinite mischief in one respect, and in another it is peculiarly important and useful, by destroying those vegetable or animal substances which incumber the earth, and are noxious on account of their putridity. The buildings

buildings (usually termed hills) which these insects erect, are in their general form like fugar-loaves, and about ten or twelve feet high; and consist of an exterior part, which is large and strong, intended partly for defence, and partly for preserving a regular degree of warmth in order to hatch the eggs and cherish the young: and an interior, which is the habitable part, divided into many apartments for the residence of the king and queen, the nursing of their progeny, the accommodation of the soldiers and labourers, or magazines of provision. The royal chamber, in the interior building, or that occupied by the king and queen, is situated near the centre, and usually in the shape of a semi-oval within.

In the infant state of the colony, it is not more than about an inch in length, but in time it is enlarged to six or eight inches in the clear, being in size adapted to that of the queen. It has doors or entrances, at pretty equal distances from each other, which entrances are of a size not to admit any animal larger than the soldiers and labourers: so that the king and queen, when once immured, can never go out. The royal chamber is surrounded by many others of different sizes, shapes, and dimensions; and they either open into each other, or communicate by passages suitably contrived. These apartments are connected with the magazines, formed altogether of clay, and nurseries. The provisions lodged in the former appear by the microscope to consist principally of the gums or inspissated juices of plants. The nurseries are composed entirely of wooden materials, joined together apparently with gums. These nurseries are occupied by the eggs, and young insects, which appear at first in the shape of labourers, but white as snow. They are very compact, and divided into small chambers, not one of which is to be found of half an inch in width. They are placed round and near the royal apartments. As the queen enlarges, her chamber is also enlarged; and new apartments are fitted up for her attendants; and also new nurseries at a remoter distance. Thus, says Mr. Smeathman, they continually enlarge their apartments, pull down, repair, and rebuild, according to their wants, with a degree of sagacity, regularity, and foresight, not even imitated by any other kind of animals or insects which he has ever heard of. These nurseries are always found slightly overgrown with or plentifully sprinkled with small white globules, about the size of a small pin's head, first supposed to be the eggs, but found by the microscope to be small mushrooms. The royal chamber is situated at about a level with the surface of the ground, at an equal distance from all the sides of the building, and in every direction surrounded by the apartments of labourers or soldiers, for the purpose of attendance. These apartments compose an intricate labyrinth, extending a foot or more in diameter, from the royal chamber on every side. Here the nurseries and magazines of provisions commence, and being separated by small empty chambers or galleries, are continued on all sides to the outward shell, and reaching up within it two-thirds or three-fourths of its height. All these chambers, and passages leading to and from them, being arched, help to support one another: and the exterior building supports them on the outside. Our limits will not allow our describing all the subterranean galleries or passages, and the manner in which they are artfully made to communicate with different parts of the building, and to suit the convenience of the labourers and soldiers, as thoroughfares for passing and repassing with their loads of materials and provisions.

There are other nests or habitations constructed by other species, which are in the form of turrets, or upright cylinders, and contain a number of cells: they are of two sizes,

for the accommodation of a larger and smaller species: and again another kind of nests, which is the habitation of a distinct species; this is generally spherical or oval, and built in trees.

Of the three orders above-mentioned, the labourers, which are about one-fourth of an inch long, and twenty-five of them weigh about a grain, are the most numerous; *e. g.* in the *T. bellicosus*, there seem to be at least one hundred labourers to one of the fighting insects or soldiers. The soldiers are about half an inch long, and equal in bulk to fifteen of the labourers; the mouth of the latter is evidently calculated for gnawing and holding of bodies, whereas that of the former, or soldiers, has its jaw shaped like two sharp awls, a little jagged, and as hard as a crab's claws, so that they are incapable of any thing but piercing or wounding: in insects of the third order, which have arrived at their perfect state, the head, thorax, and abdomen, are wholly different from those of the other orders, and they are furnished with four large brownish transparent wings; their length is six or seven-tenths of an inch, and each is equal in bulk to thirty labourers: they have now two eyes which are visible, whereas if they had them before they are not distinguishable. These insects are gathered and eat by the inhabitants, and reckoned both delicious and nourishing food. The king and queen are lodged in apartments, which are closed up, so that a passage remains merely for the ingress and egress of the labourers and soldiers, but at which (as we have already said) neither of the royal pair can come out: and in the business of propagation the abdomen of the female extends to an enormous size, so that an old queen's will be fifteen hundred or two thousand times the bulk of the rest of her body, and twenty or thirty thousand times the bulk of a labourer, and by its peristaltic motion, are protruded eggs to the amount of sixty in a minute, or eighty thousand and more in twenty-four hours: the eggs are removed by the attendants into the nurseries, and after they are hatched, the young are provided with every thing necessary till they are able to shift for themselves. It is remarkable of all the different species of termites, that the working and fighting insects never expose themselves to the open air; but either travel under ground, or within such trees or substances as they destroy, or through pipes made of the same materials with their nests. The termites which build in trees, frequently construct their nests within the roofs and other parts of houses, to which they do considerable damage, unless soon extirpated; and the larger species enter under the foundations of houses, through the floors, or bore through the posts of buildings, making lateral perforations and cavities, as they proceed. They are equally destructive when they get into a trunk containing clothes and other things, and into stores, &c.

Upon opening the hills in which the termites lodge, the behaviour of the soldiers excites admiration. When a breach is made, however quickly it be done, a soldier will run out, and walk about the breach, as if to see whether the enemy is gone, or to examine what is the cause of the attack. He will sometimes return again, as if to give the alarm; but in a short interval he is followed by two or three others, running as fast as they can, and these are followed by a large body, others also succeeding them, as long as any one continues to batter their building: nor is it easy to describe the rage and fury which they manifest on the occasion; biting every thing in their way, and making a vibrating noise, like the ticking of a watch, perceptible at the distance of three or four feet. If they get hold of any one who attacks their habitation, they will in an instant suck out blood enough to weigh against their whole body; and if they chance to wound the leg, the stain upon the stocking will be seen to extend an inch

in width. They make their hooked jaws to meet at the first stroke, nor will they quit their hold, but suffer themselves to be pulled away leg by leg, and piece after piece, without the least attempt to escape. If, however, they are left to themselves undisturbed, they will in less than half an hour retire into the nest, as if they conceived their castle to be secure. Before they all get in, the labourers will be seen in motion, hastening to bring materials for repairing the breach. This they do without mutual obstruction, though their number be immense, and the work is soon finished. While the labourers are thus employed, the soldiers take no part with them. On a renewed attack, the labourers run with celerity into the numerous pipes and galleries with which the building is perforated; and the soldiers rush out as numerous and as vindictive as before. One circumstance more deserves to be mentioned; and that is the loyalty and fidelity displayed by the labourers and soldiers in their attendance on the royal chamber. This chamber is a large nest, is capacious enough to hold many hundreds of the attendants, besides the royal pair, and it is always found full. These faithful subjects never abandon their charge in the last distress, but rather die in their defence than desert them. 'If in an attack upon the hill, you stop short of the royal chamber, and cut down about half of the building, and leave open some thousands of galleries and chambers, they will all be shut up with their sheets of clay before the next morning. If even the whole is pulled down, and the different buildings are thrown together in a heap of confused ruins, provided the king and queen are not destroyed or taken away, every interstice between the ruins, at which either cold or wet can possibly enter, will be so covered, as to exclude both; and if the insects are left undisturbed, in about a year they will raise the building to nearly its pristine size and grandeur.

There is another species, called the *marching* termites, which is much larger, and seems to be less frequent than the other. For an account of those, and many other curious particulars, we must refer to Philos. Trans. vol. lxxi. part i. art. 11. p. 139—192.

TERMIGON, in *Geography*, a town of France, in the department of Mont Blanc, on the Arc; 12 miles E.N.E. of St. André.

TERMINALIA, in *Antiquity*, feasts celebrated by the Romans, in honour of the god Terminus.

Varro is of opinion, that this feast took its name from its being at the term or end of the year; but Festus is of a different sentiment, and derives it from the name of the deity in whose honour it was held.

In reality, the Terminalia, or feasts of land-marks, were held in honour of Jupiter, considered in the capacity of conservator of land-marks or bounds. Dionysius Halicarnassicus tells us, that it was Numa Pompilius who first consecrated land-marks to Jupiter; and adds, that the same prince appointed an anniversary day, on which the country-people, assembling together on the bounds of the lands, should offer sacrifices in honour of the tutelary gods thereof.

The Terminalia were held on the seventh, or, as Struvius will have it, on the tenth of the calends of March. No animal is to be sacrificed herein, it being deemed unlawful to stain the land-marks with blood: they only offered sacrifices of the first fruits of the earth; and this in the open air, and on the spot where the land-marks were.

TERMINALIA, in *Botany*, from the terminal mode of growth and foliation in several of the species, the stem being a striking example of what Linnæus latterly called *determinatè ramifusus*, and the leaves being crowded at the ends of the branches, which are swelled in that part.—Linn. Mant. 21. Schreb. Gen. 728. Willd. Sp. Pl. v. 4. 967,

Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 441. Jacq. Coll. v. 1. 130. Juss. 76. Lamarck Illustr. t. 848. (Pamea; Aubl. Guian. 946. Tanibouca; -ibid. 448? Badamia; Gært. t. 97. Myrobalanus; Gært. ibid. Lam. Illustr. t. 849.)—Class and order, *Polygamia Monoecia*, Linn. Rather *Decandria Monogynia*.

Gen. Ch. *Cal.* Perianth superior, of one leaf, internally coloured, in five ovate, acute, equal segments. *Cor.* Petals none. Nectary pitcher-shaped, composed of five small hairy lobes, in the bottom of the calyx. *Stam.* Filaments ten, awl-shaped, slightly spreading, longer than the calyx, inserted into its lower part; anthers roundish, erect. *Pist.* Germen inferior, ovate-oblong; style thread-shaped, erect, the length of the stamens; stigma simple. *Peric.* Drupa oval, somewhat compressed, acute. *Seed.* Nut oval-oblong, angular, smooth, with an oblong solitary kernel.

Numerous flowers, above the others, and later, are entirely male.

Eff. Ch. Calyx in five segments, internally coloured. Petals none. Nectary five-cleft, hairy. Drupa inferior.

1. *T. Catappa*. Broad downy-leaved Terminalia. Linn. Mant. 128. Willd. n. 1. Ait. n. 1. Jacq. Coll. v. 1. 130. Ic. Rar. t. 197. (Adamaram; Rheede Hort. Malab. v. 4. 5. t. 3, 4.)—Leaves obovate, obtuse, very slightly toothed, destitute of glands at the base; finely downy beneath.—Native of the East Indies, in Java and in woods on the coast of Malabar, where the soil is sandy. Messrs. Lee and Kennedy are said to have introduced this tree into the English stoves in 1778, but it has not yet blossomed, nor, considering its natural and lofty growth, is that event to be expected. The branches grow in a whorled manner; their extremities, clothed with rusty down, bearing each a close tuft of large broad leaves, a foot long, on short downy stalks. Each leaf is tipped with a small point, and is abrupt or somewhat heart-shaped, though much contracted, at the base. Clusters numerous, axillary, stalked, cylindrical, dense, many-flowered. Flowers greenish-yellow, half the size of a currant-blossom, most of them males. Fruit oval, compressed, larger than that of the almond-tree, reddish, with a cylindrical kernel, which tastes like a silberd, but is more tender and soluble. Its oil is said never to turn rancid. The wood is hard and durable, and the tree is much planted about houses, for the sake of its shade.

2. *T. moluccana*. Molucca Terminalia. Lamarck Dict. v. 1. 349. Willd. n. 2. Ait. n. 2. (*T. glabrata*; Forst. Prodr. 74. Pl. Escul. 52. Spreng. Antiq. Bot. 102. t. 2. Catappa; Rumph. Amboin. v. 1. 174. t. 68.)—Leaves obovate, obtuse, entire, destitute of glands at the base; smooth on both sides.—Native of the Molucca and Society isles. Introduced into the English stoves by the earl of Powis, in 1804. This is said to be of a more humble stature than the foregoing, and the leaves are smaller, smooth at the back, though their footstalks are covered with dense rusty down. The specific name of *glabrata* ought to have been retained in preference to *moluccana*. This is considered as a sacred tree in Otaheite, though used in building boats as well as houses.

3. *T. subcordata*. Heart-leaved Terminalia. Willd. n. 3.—“Leaves obovate, obtuse, somewhat wavy; smooth on both sides, heart-shaped at the base, without glands.”—Gathered by Humboldt and Bonpland, in South America. Willdenow, who had examined one of their dried specimens, says “this species is very like the last, but the base of the leaves is heart-shaped, and their margin very slightly and unequally wavy; the footstalks somewhat downy. It differs from *T. Catappa*, in having the leaves somewhat wavy, very smooth

smooth on both sides, and heart-shaped at the base."—This last character seems to us to exist in *T. Catappa*.

4. *T. latifolia*. Broad wedge-leaved Terminalia. Swartz Ind. Occ. 747. Willd. n. 4. (*Arbor maxima, fortè prunifera, cortice cannabino, folio longissimo latissimoque*; Sloane Hist. v. 2. 130.)—Leaves obovate, obtuse, somewhat ferrated, smooth on both sides, destitute of glands at the base: their midrib downy beneath.—Native of mountainous woods in the north part of Jamaica. A tall, stout, umbrageous tree, rising to the height of one hundred feet, or more, with horizontal branches, downy when young. Leaves crowded about the ends of the branches, on smooth stalks, thickish, scarcely pointed, bluntly ferrated, or nearly entire, tapering (not dilated or heart-shaped) at the base. Flowers small, whitish or yellowish, in long axillary clusters: the upper ones chiefly male. Fruit pulpy, greenish-red, sweet, boat-shaped, larger than a peach, eaten chiefly by hogs. Its kernel tastes like an almond. The wood is valuable for its hardness. The inhabitants of Jamaica know this species by the name of Broad-leaf Tree. Swartz.

5. *T. Chebula*. Oval-leaved Terminalia. Retz. Obs. fasc. 5. 31. Willd. n. 5. Ait. n. 3. Roxb. Coromand. v. 2. 52. t. 197. (*Myrobalanus Chebula*; Gært. v. 2. 91. t. 97.)—Leaves obovate-oblong, obtuse, entire, opposite, smooth on both sides; silky when young. Footstalks with two glands near the top. Clusters terminal.—Native of hills in the East Indies. Retzius, who received his specimens from Koenig, describes this tree as not more than three or four times the height of a man, with no very widely spreading top. Our specimens, from Dr. Rottler, agree with every particular of his description. The young leaves are beautifully silky. We find none of the marginal glands represented by Roxburgh, nor are our leaves pointed, as in his plate. The flowers in both are yellow, in terminal, often aggregate, clusters. Dr. Roxburgh mentions the wood of the tree he describes as hard and valuable, and the head as evergreen, and widely spreading. The rind of its fruit is much used by painters of chintz for drawing a permanent outline, and by dyers to fix their colours. With salt of steel it makes an excellent ink.

6. *T. elliptica*. Rounded-leaved Terminalia. Willd. n. 6.—"Leaves oblong-elliptical, bluntly rounded, entire; slightly hairy beneath, with two glands at the base."—Native of the East Indies. The branches are round, brown; downy when young. Leaves two or three inches in length; contracted at the base; very obtuse at the extremity, with a slight point; dark green and smooth above; pale, and besprinkled with close-pressed scattered hairs, beneath; furnished at the base with two cup-shaped, somewhat stalked, glands. Spikes terminal, paniced. Willdenow. We have been inclined to suspect this might not be distinct from the following, but the inflorescence does not agree, nor could Willdenow surely have omitted to notice the great length of the footstalks in *T. Bellerica*.

7. *T. Bellerica*. Long-stalked Terminalia. Roxb. Corom. v. 2. 54. t. 198. (*Myrobalanus Bellerica*; Breyn. Ic. 18. t. 4. Gært. v. 2. 90. t. 97. Tani; Rheede Hort. Malab. v. 4. 23. t. 10.)—Leaves obovate, wavy, smooth. Footstalks about half as long as the leaves, with two glands at the top. Spikes axillary, solitary, hardly longer than the footstalks.—Native of hills in the East Indies. A large tree, with a very widely spreading head; the wood is white, but soft, and not durable. The bark, when wounded, exudes a copious insipid gum, like gum arabic, soluble in water. The leaves are firm and smooth, six or seven inches long when full-grown, but in the flowering season they seem scarcely to exceed their footstalks, which then measure half

that length. Flowers fetid, dirty yellow, in copious axillary spikes, not clusters. Fruit the size of a nutmeg; its kernel eatable, but reported to intoxicate if taken in any great quantity.

8. *T. mauritiana*. Mauritius Terminalia. Lamarck Dict. v. 1. 349. Willd. n. 7. (*Badamia Commerfoni*; Gært. v. 2. 90. t. 97? *Pamea guianensis*; Aubl. Guian. v. 2. 946. t. 349?)—Leaves lanceolate, slightly crenate, tapering at each end, smooth on both sides. Spikes axillary, the length of the leaves.—Native of the isles of Mauritius and Bourbon, and probably of Madagascar. Commerfoni describes it as the largest and tallest tree of the two former islands. He took it for a new genus, and named it *Resnaria*, under which name, and that of *le faux benjoin*, his specimens are preserved in the Linnæan herbarium. The wood is much esteemed for making canoes. The branches are swelled at the ends, where they bear ample tufts of leaves three or four inches long, on downy stalks, three-quarters of an inch in length; when full-grown both appear, by Lamarck's account, to be much larger. Flowers copious, in simple axillary spikes. Fruit an inch or inch and half long, with a dilated compressed border, not altogether answering to Gærtner's figure, which makes us doubt his synonym. He has formed his barbarous generic name, *Badamia*, out of the French *Badamier*, which is synonymous with *Terminalia*. Aublet's plate of his *Pamea* greatly resembles our plant, and our chief doubt arises from their distant places of growth. That they are of the same genus cannot be disputed.

9. *T. angustifolia*. Narrow-leaved Terminalia. Jacq. Hort. Vind. v. 3. 51. t. 100. Willd. n. 8. Ait. n. 4. (*T. Benzoin*; Linn. Suppl. 434. Lamarck Dict. v. 1. 349. Croton Benzoe; Linn. Mant. 297. Willd. Sp. Pl. v. 4. 533.)—Leaves linear-lanceolate, wavy, downy on both sides.—Native of the East Indies. Jacquin reports that seeds of this species were sent him by Lemonnier, under the French name of *Bien-joint*, from the isle of Bourbon. Hence he ingeniously and satisfactorily conjectures, that this appellation, which alludes to the mode of growth of the tree, may have been confounded with *Benjoin* or *Benzoin*, the French word for gum Benjamin, or *Benzoe*, and thus the said gum was supposed to come from the plant before us. (See STYRAX.) *T. angustifolia* has long been cultivated in our stoves, but the flowers are unknown. Its manner of branching is like *T. Catappa*, *mauritiana*, &c. nor does it much differ from the last named, except that the leaves are narrower, often quite linear, and clothed, more or less completely, with brown, rather rigid, hairs. Their veins, rib, and margin are tinged with a blood-colour. The fruit appears to be similar to the last. Linnæus raised a plant from seed in the Upsal stove, and remarked that the seed-leaves were of a blood-red. The leaves of his specimen hardly exceed a line in breadth.

10. *T. Vernix*. Varnish Terminalia. Lamarck Dict. v. 1. 350. Willd. n. 9. (*Arbor vernicis*; Rumph. Amboin. v. 2. 259. t. 86.)—Leaves linear-lanceolate, entire, smooth on both sides.—Native of the Molucca isles. It is presumed to belong to this genus from the imperfect description of Rumphius, and its evident resemblance to the two last species. The leaves however are more dispersed, and of larger dimensions, being from nine to eleven inches long, and the breadth of three or four fingers, so that they are scarcely to be termed linear-lanceolate. The rib is very prominent beneath. Flowers yellow or whitish, with red stamens, in drooping clusters or spikes. Fruit oblique and compressed, two inches broad. The nut exudes a large quantity of resin, soon turning brown, and a milky resinous fluid is lodged under the bark of the tree, at first of an acrid quality, but

hardening into a valuable varnish, destitute of acrimony, and much used in the Moluccas. A noxious vapour is said to proceed from this tree, so that the natives of the countries where it grows avoid sleeping, or even sitting for any length of time, under its shade. Whether this be the most famous varnish-tree of the Chinese, as Rumphius indicates, may perhaps admit of doubt.

11. *T. Tanibouca*. Guiana Terminalia. (Tanibouca guianensis; Aubl. Guian. 448. t. 178.)—Leaves scattered, obovate, pointed, entire, smooth. Clusters terminal and axillary. Native of marshy places in Guiana. For an account of this species, see TANIBOUCA. Its genus must be very doubtful, unless the fruit were known, but the suggestion of our learned friend Mr. Brown, Prodr. Nov. Holl. v. 1. 351, induces us, for the present at least, to refer the plant hither.

TERMINANDO *et Audiendo*. See AUDIENDO.

TERMINANS, PUNCTUM. See PUNCTUM.

TERMINATION, TERMINATIO, in *Grammar*, the ending of a word, or the last syllable of it.

They are the different terminations of one and the same words on different occasions, that constitute the different cases, numbers, tenes, moods, &c.

TERMINATION *Island*, in *Geography*, an island in the South Pacific ocean, so named by captain Vancouver, as being the termination of his researches on the S.W. coast of New Holland, near which it lies. S. lat. 34° 32'. E. long. 122° 8'.

TERMINATOR, in *Astronomy*, a name sometimes given to the *circle of illumination*, from its property of terminating the boundaries of light and darkness.

TERMINE, in *Commerce*, a weight for gold, silver, and pearls at Tunis; 8 termini being equal to an ounce; and 80 ounces of Tunis being equal to 81 ounces English troy.

TERMINE, in *Geography*, a town of Naples, in Principato Ultra; 10 miles S.E. of Avellino.

TERMINER, in *Law*. See OYER.

TERMINI, in *Architecture*. See TERMS.

TERMINI, in *Geography*, a town of Sicily, in the valley of Mazara, situated on the north coast, celebrated for the warm baths near it, from which it received its name; 18 miles E. of Palermo. N. lat. 38° 5'. E. long. 13° 45'.—Also, a river of Sicily, which runs into the Mediterranean, a little to the W. of Termini.

TERMINI. See TERMOLI.

TERMINISTS, TERMINISTÆ, in *Ecclesiastical History*, a sect or party among the Calvinists, whose particular tenets are reducible to five points:

1. That there are several persons, both in and out of the church, to whom God has fixed a certain term before their death, after which he no longer wills their salvation, how long soever they live afterwards.
2. That God has fixed this fatal term of grace by a secret decree.
3. That this term once elapsed, he makes them no farther offer of repentance or salvation, but takes away from his word all the power it might have to convert them.
4. That Pharaoh, Saul, Judas, most of the Jews, and many of the Gentiles, were of this number.
5. That God still bears with several of this sort of people, and even confers benefits on them after the term is expired; but that he does not do it with any intention they should be converted.

All the other Protestants, and particularly the Lutherans, look on these articles with abhorrence, as repugnant to the goodness of God, and destructive to all Christian virtue; and as contrary to Scripture, particularly the following texts, Ezek. xviii. 23. 30, 31, 32. xxxiii. 11. 1 Tim. iv.

1. 16. 2 Pet. iii. 9. Acts, xvii. 30, 31. Matt. xi. 28. Isa. lxvi. 2. Heb. iii. 7. 13. Rom. ii. 5, &c.

TERMINOS, in *Geography*, a lake or bay on the coast of Tabasco, in the bay of Campeachy. N. lat. 18° 12'. W. long. 92° 46'.

TERMINTHUS, from *τεμινθος*, a pine-nut, in *Surgery*, a large painful tumour, or pustule on the skin, thought to resemble a pine-nut.

TERMINUM, *ad qui praterit*. See AD TERMINUM.

TERMINUM, *Infra, quare ejecit*. See QUARE.

TERMINUS, *τεμινθ*, signifies a bound or limit.

TERMINUS, *a quo*, in *Metaphysics*, denotes the place from whence any motion commences: in contradistinction from the other extreme, which is called the *terminus ad quem*.

The schoolmen call privation a *terminus a quo*, in speaking of generation, which they consider as a species of motion.

TERMINUS, in *Mythology*, the god of fields and land-marks. M. de Boze, in a learned dissertation on this subject (Mem. de l'Acad. t. i.), observes, that the Egyptians received from the Hebrews the custom of bounding the fields. In process of time, as the laws established for the security of the land-marks were not a sufficient restraint on avarice, Numa persuaded the people that there was a god who protected land-marks and avenged incroachments. He built a temple to him upon the Tarpeian mount, and regulated the ceremonies of his worship. He caused this god to be represented under the form of a flock or stone, as we learn from Tibullus and Ovid: but afterwards this god was represented with a human body placed upon a pyramidal land-mark. It is said that this god acquired peculiar honour by maintaining his station when the other gods were removed by Tarquin the Proud, for the purpose of building the temple which Tarquin the elder had vowed to erect to Jupiter.

TERMIOVA, in *Geography*, a town of Iltria; 18 miles N.E. of Pedena.

TERMISSUS, or TELMISSUS, in *Ancient Geography*, a town of Asia, in the southern part of Pisidia.

TERMITES, in *Entomology*. See TERMES.

TERMOLI, or TERMINI, in *Geography*, a town of Naples, in the province of Capitanata; the see of a bishop, suffragan of Benevento; 57 miles W. of Vieste. N. lat. 42° 2'. E. long. 15° 5'.

TERMOR, *Tenens ex termino*, in *Law*, he that holds lands or tenements for a term of years, or life.

TERMUS, in *Ancient Geography*, a river in the isle of Sardinia.

TERN, in *Geography*, a river of England, which rises in Staffordshire, 5 miles N.E. of Drayton, and runs into the Severn, 7 miles below Shrewsbury.

TERN. See TYRAN.

TERN, in *Ornithology*. See STERNA.

TERN, *Brown*, or *Sterna obscura* of Linnæus, is by some authors called the *brocwn gull*. Mr. Ray describes it as having the whole under side white, the upper brown; the wings partly brown, partly ash-colour; the head black; and the tail not forked: but Mr. Pennant conjectures, that this bird is the young of the greater tern. See STERNA.

TERN, *Great*, or *Sea-swallow*, *Sterna hirundo* of Linnæus, has the bill and feet of a fine crimson, the former tipped with black, straight, slender, and sharp-pointed; the crown and hind part of the head black; the throat and whole under side of the body white; the upper part, and coverts of the wings, a pale grey; the tail consisting of twelve feathers, the outer edges of the three outmost grey, the rest white, and the

the exterior on each side two inches longer than the other, and closed in flying, so as to appear one slender feather.

These birds frequent the sea-shores, banks of lakes, and rivers; they feed on small fish and water insects, hovering over the water, and suddenly darting into it to catch their prey. They breed among small tufts of rushes, and lay three or four eggs of a dull olive-colour, spotted with black. All the birds of this genus are very clamorous. Pennant.

TERN, *Black*, or *Scare-crow*. See STERNA *Filipes*.

TERN, *Surinam*, or *Darter*. See PLOTUS *Surinamensis*.

TERNA, a word used by some authors to express an impetigo.

TERNA, *Folia*, in *Botany* and *Vegetable Physiology*, are leaves, whether simple or compound, sessile or stalked, which grow three together in a whorl, on any stem or branch, as in *Verbena triphylla*, Curt. Mag. t. 367. Such a disposition of the foliage appears to prevail remarkably among the plants of Mexico, Chili, and Peru, of which, besides the example just named, many others may be found. (See the genera FUCHSIA and HEMIMERIS.) Among British plants, *Erica cinerea* has naturally *folia terna*; while the generally opposite leaves of *Lysimachia vulgaris* and *Lythrum Salicaria* occasionally become so. See LEAF.

TERNALLA, in *Geography*, a town of Hindoostan, in Mysore; 45 miles E. of Rettinghery.

TERNARY MEASURE. See MEASURE.

TERNARY Number, in *Antiquity*, was esteemed a symbol of perfection, and held in great veneration among the ancient mythologists. Whence Virgil,

—“Numero Deus impare gaudet.” Ecl. viii. ver. 75.

Servius on this place remarks, that the Pythagoreans ascribed the ternary number to the Supreme God, as being the beginning, middle, and the end of all things. All the heathen gods had a three-fold power attributed to them, as the *tria virginis ora Dianæ*, the three-forked thunderbolt of Jupiter, the trident of Neptune, the three-headed dog of Pluto. Again, the *Parcæ* were three, the *Furies* three, Hercules was three nights in begetting, the *Muses* were anciently three, the *Graces* three, &c.

This number was likewise used in most religious ceremonies, but especially in lustrations; whence Virgil, *Æn.* lib. xi. v. 188.

“Ter circum accensos, cincti fulgentibus armis,
Decurrere rogos.”

TERNATA, FOLIA, in *Botany* and *Vegetable Physiology*, are compound leaves, each of which consists of three leaflets, as in the Trefoil and Strawberry. These are called in English Ternate Leaves, and must not be confounded with *Folia TERNA*, see that article, for which last we have no appropriate term in our language. Some plants bear twice, or thrice, ternate leaves. See LEAF.

TERNATE, in *Geography*, an island in the East Indian sea, and the principal, though not the largest, among those called Moluccas or Spice Islands, of a circular form, and about 21 miles in circumference. In the centre is a lofty volcanic mountain, whose base extends almost to the sea every way. The upper parts are uncultivated, and covered over with shrubs and low trees; but in the plain are many gardens, and abundance of fruit-trees. On this mountain are found many hollows or caverns full of sulphur, which emit a thick smoke, and flame sometimes appears from the fummit, with a noise resembling thunder. The productions are cocoa-nuts, bananas, yams, oranges, and other fruits; but the principal article of commerce is cloves:

many birds of paradise, and other beautiful birds, are found here, and plenty of game. The chief quadrupeds are goats, deer, and hogs. The boa serpent is sometimes found of the length of thirty feet. This island was first settled by the Spaniards, who were driven away by the Dutch, to whom the king of the island is, in some degree, subject. The Europeans have two forts, called “Orange” and “Terloehé,” between which is a lake, called “Sasse,” three miles in circumference, and 60 fathoms deep, separated from the sea by a narrow dike, which the Spaniards made a fruitless attempt to cut through, to form a port. On this island are three mosques, and a Dutch church, but no place of worship for the Portuguese. The province or government of Ternate includes the islands of Ternate, Tidore, Motir, Machian, and Bachian, which are what are properly the Moluccas; they are the original places of growth of the finer spices; and larger nutmegs are still found in the woods of Ternate, than any other produced out of Banda. Some places, situated in the eastern part of the island of Celebes, belong likewise to this government; and the object of the Company in settling there is principally to furnish provisions for Ternate, that part of Celebes being very fruitful in rice and other necessaries. They also yield a considerable quantity of gold, about 24,000 taels, of a dollar and a half in weight, yearly, amounting, at 5*l.* per tael, to 120,000*l.*, and excellent bird’s-nests, which are esteemed a great delicacy by the Orientals, and especially by the Chinese; in exchange for which the inhabitants take opium, Hindoostan piece-goods, chiefly blue cloth, fine Bengal coffees and hummums, together with some cutlery. Ternate does not, in general, require any supply of provisions from Java, as the isles of Banda do. This island suffered greatly in August 1770, by earthquakes. More than sixty violent shocks were felt in the space of twenty-four hours, and the fortifications were much injured. N. lat. 0° 50'. E. long. 127° 10'.

TERNATE, in *Zoology*, a species of bat. See VAMPYRE, and VESPERTILIO *Vampyrus*.

TERNATEA, in *Botany*, a genus so named by Tournefort, from Ternate, the native country of the plant. See CLITORIA.

TERNAVASSO, in *Geography*, a town of France, in the department of the Po; 6 miles N.E. of Carmagnola.

TERNAY, *Bay of*, a bay or harbour on the E. coast of Chinese Tartary, so called by M. Perouse in 1787. The Dutch navigators called it Port Acqueis. N. lat. 45° 13'. E. long. 137° 29'.

TERNBERG, a mountain of Austria, near the river Enns; 6 miles S. of Steyr.

TERNEUSE, a town and fortress of Flanders, situated on the W. branch of the Scheld, called the “Hondt,” begun by the count of Hohenloe, lieutenant of the prince of Orange, in the year 1583, afterwards augmented by the States: the fortifications have been since destroyed; 12 miles S.E. of Flushing.

TERNI, a town of the Papedom, in the duchy of Spoleto, situated between two arms of the Nera, and, therefore, anciently called “Interamnium,” or “Interamna.” It is well built, and the see of a bishop, immediately subject to the pope. Its greatest trade consists in oil, besides which it also reaps considerable advantage from its excellent vineyards. This was the birth-place of the emperors Tacitus and Florianus, and of Tacitus the famous historian. Between six and seven Italian miles from Terni, to the N.W. close by the little town of Cesi, is Mount Eolo, remarkable for its cool breezes, which, especially in summer, issue from the chafms and crevices in the rocks of this mountain; 14 miles S.S.W. of Spoleto. N. lat. 2° 34'. E. long. 12° 37'.

TERNIER, a town of France, in the department of the Lemane; 5 miles S.S.W. of Geneva.

TERNOIS, LE, a river of France, which runs into the Canche, near Hesdin.

TERNOSKAIA, a town of Russia, in the country of the Cossacs, on the Don; 136 miles E.N.E. of Azoph.

TERNOVA, a town of European Turkey, in Bulgaria. This town was anciently one of the strongest in the country, and the residence of the princes; at present it is thinly inhabited, and the fortifications are ruined. It is the residence of an ecclesiastic, who is called the archbishop of Bulgaria; 95 miles E. of Sophia. N. lat. 43°. E. long. 25° 24'.—Also, a town of European Turkey, in Thessaly; large and commercial; on the Peneus; 5 miles W.N.W. of Larissa.

TERNSTROEMIA, in *Botany*, was so called by Linnæus at the suggestion of Mutis, in memory of one of the pupils of the former, named Ternstroem, who having undertaken a voyage to China, in 1745, died at Poulicandor, at an early age. His illustrious teacher has not, as in other instances, given us any account of the voyage, discoveries, or talents of this unfortunate young man, who, though not one of his favourite pupils, deserves commemoration as a martyr to scientific research.—Linn. Suppl. 39. Schreb. 347. Willd. Sp. Pl. v. 2. 1128. Mart. Mill. Dict. v. 4. Swartz Prodr. 81. Juss. 262. (Cleyera; Thunb. Jap. 12. Nov. Gen. 68. Juss. 433. Taonabo; Aubl. Guian. 569. Tonabea; Juss. 262. Tanabea; Lamarck Illustr. t. 456.)—Class and order, *Polyandria Monogynia*. Nat. Ord. akin to *Thea* and *Camellia*. Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, orbicular, concave, rather unequal segments, with two smaller ones closely applied to its base, all permanent and coriaceous. *Cor.* of one petal, bell-shaped, in five deep, orbicular, concave, emarginate segments, longer than the calyx, without any tube. *Stam.* Filaments numerous, awl-shaped, shorter than the corolla, and inserted into its base in a double row; anthers linear, erect, the length of the filaments. *Pist.* Germen superior, roundish; style cylindrical, as long as the stamens; stigma capitate. *Peric.* Berry dry, ovate, smooth, of two cells. *Seeds* about eight, convex on one side, flat on the other.

Eff. Ch. Corolla bell-shaped, in five deep segments, without a tube. Calyx in five deep segments, with two smaller at the base. Berry dry, of two cells.

1. *T. meridionalis*. Mexican Ternstroemia. Linn. Suppl. 264. Willd. n. 1.—Leaves obovate, obtuse, emarginate, entire. Flower-stalks axillary, compressed, recurved. Two outer segments of the calyx orbicular, sharply keeled.—Gathered by Mutis in Mexico and New Granada. A tree, determinately branched; the branches thick, rigid, leafy, nearly round, with a smooth grey bark. *Leaves* alternate, an inch or rather more in length, on short, thick, channelled, purplish footstalks, obovate, or nearly elliptical, peculiarly rigid and coriaceous, single-ribbed, smooth, with a thick somewhat revolute margin; their upper surface often dotted with either prominent or depressed points; the under purplish or rusty, especially when young. *Stipulas* none. *Flower-stalks* numerous, axillary, solitary, half the length of the leaves, very thick and rigid, two-edged, brown or purple, curved downwards, destitute of pubescence, but, in the dried plant at least, wrinkled and uneven. *Flowers* larger than a hawthorn-blossom, white. The two smaller external scales of the calyx furnished with a sharp keel, ending in a minute point; the rest without any keel, thin and membranous at the edge; all smooth, orbicular, coriaceous, permanent. *Corolla* occasionally with six segments, at first

globose, then bell-shaped. *Berry* dry, destitute of valves. *Seeds* silky, deep red. Such is the plant of Mutis. We have no means of ascertaining whether the West Indian one, described by Swartz in his *Observationes*, be the same or not; but he says the *flower-stalks* are terminal, nor does he advert to their clumsy two-edged figure, so different from the rest of the species, that it could scarcely have escaped his notice.

2. *T. elliptica*. Elliptical Ternstroemia, or Rottenbanc. Swartz Ind. Occ. 929. Willd. n. 2. Vahl Syn. v. 2. 61.—Leaves obovate, obtuse, entire. Flower-stalks lateral, elongated, nearly thread-shaped. Outer segments of the calyx ovate, acute, bluntly keeled.—Native of the West Indies, on the Sulphur mountains of Montserrat and Guadeloupe, as well as in St. Vincent's. It is said to be the pretended Jesuit's bark, mentioned by Labat. This is a *shrub* with stout, round, smooth, dispersed or clustered branches, leafy towards their extremities. *Leaves* like the last, but twice as long, and not emarginate; their *footstalks* longer and more slender. *Flower-stalks* an inch and half or two inches long, but slightly drooping or recurved, nearly round, not a quarter so stout as the last, slightly swelling upward, red or purplish. *Flowers* rather larger than the foregoing, yellowish-white, some of them destitute of a pistil. The scales of the calyx are all pointed, the outer ones narrow and ovate, of a smaller proportion than in *T. meridionalis*, and sometimes more than two.

3. *T. japonica*. Japan Ternstroemia. Thunb. Tr. of Linn. Soc. v. 2. 335. Willd. n. 4. (Cleyera japonica; Thunb. Jap. 224. Mokokf; Kämpf. Am. Exot. 873. t. 774.)—Leaves obovato-lanceolate, obtuse, nearly entire. Flower-stalks lateral, somewhat angular. Outer segments of the calyx triangular, pointed, slightly keeled.—Gathered by Thunberg, near Nagasaki in Japan, flowering in autumn. This is a *tree*, smooth in every part. Specimens sent us by the finder are so very nearly akin to the two foregoing species, that it is hard to establish a specific difference between them. The *leaves* of the Japan plant however are rather more lanceolate, and their margin is sometimes, not constantly, crenate towards the point. Their surface is quite smooth, not visibly dotted. The *flower-stalks*, about an inch long, are scattered on the branches, below the leaves, but slightly recurved, usually triangular, not compressed. *Flowers* white, scarcely so large as in *T. meridionalis*. *Style* short and thick. *Berry* the size of a currant, red, pointed, with a white, sweet, subastringent pulp, and, according to Kämpfer, only one pellucid seed.

4. *T. punctata*. Dotted-edged Ternstroemia. Swartz Prodr. 81. Willd. n. 3. (Taonabo punctata; Aubl. Guian. 571. t. 228.)—Leaves elliptic-oblong, dotted at the edge. Flower-stalks axillary, elongated, nearly thread-shaped. Segments of the calyx all pointed.—Gathered by Aublet on the sides of the Serpent mountain in Guiana, bearing flowers and fruit in August and September. A large tree, whose leaves are bordered with minute glandular points, rough to the touch; their extremity usually emarginate; their length about three inches. *Flower-stalks* slender, about half as long as the leaf with its footstalk. *Stamens* about sixty. *Fruit* ovate, pointed, of five or six cells. Aublet having seen it in an unripe state only, took it for a capsule, but Swartz asserts it to be a *berry*.

5. *T. dentata*. Toothed Ternstroemia. Swartz Prodr. 81. Willd. n. 5. (Taonabo dentata; Aubl. Guian. 569. t. 227.)—Leaves elliptical, pointed, strongly serrated. Flower-stalks lateral or axillary, single-flowered.—Gathered by Aublet, in the same place as the preceding, and at the same season. A tree, whose trunk is twenty-five feet, or more,

in height, and two in diameter, crowned with an ample tuft of spreading branches. The *leaves* are four inches long, and an inch and half or two inches broad, thick, smooth, tapering at each end, beset with tooth-like serratures in the margin. *Footstalks* slender, an inch long. *Flower-stalks* recurved, scattered, hardly an inch in length. *Flowers* yellowish, the size of hawthorn. *Fruit* like the last. The *bark* of the tree is used for tanning leather. The *wood* serves instead of tiles for houses.

6. T? *corymbosa*. *Corymbose Ternstroemia*?—Leaves opposite, elliptical, pointed, entire. Panicle forked, corymbose, many-flowered, terminal.—Native of Guiana. *Mr. Rudge*. This appears to be most akin to the last in the shape and size of its *leaves*, but differs in their entire margin, and opposite insertion. The three-forked *panicle* is, moreover, a kind of inflorescence unexampled in *Ternstroemia*, and the *calyx* wants the two small external segments. All these circumstances induce a suspicion of the genus, which we have not materials to clear up.

We cannot take leave of *Ternstroemia* without adverting to the mischiefs which arise from the barbarous and unsettled principles of French nomenclature. Jussieu professes to adopt the uncouth names of Aublet, only till the genera of that author are better settled; yet he has tried to soften down *Taonabo* into *Tonabea*, a needless change if the name were not to remain. Lamarck prefers *Tanabea*; so our memories and our indexes would have become burthened with three names instead of one, all intolerable to a classical or literary botanist, if the genus had not happily been superseded.

TEROE, in *Geography*, a town of Bengal; 25 miles E. of Ramgur.

TEROUANNE. See THEROUANNE.

TEROWA, a town of the island of Junkfeilon, near the east coast; the usual residence of a Siamese governor or viceroy. Here is a pagoda, with about twenty priests. N. lat. 8° 13'.

TERPANDER, in *Biography*, and *Music of the Ancients*, one of the most renowned musicians of antiquity. It is recorded in the Oxford Marbles, that he was the inventor of characters to express musical sounds in the several genera; which event is placed about six hundred and seventy years before the Christian era. Indeed all writers who mention the progressive state of music in Greece, are unanimous in celebrating the talents of Terpander; but though there is such an entire agreement among them concerning the obligations which the art was under to this musician in its infant state, yet it is difficult to find any two accounts of him which accord in adjusting the time and place of his birth. It does not, however, seem necessary to lead the reader over hedge and ditch with chronologers, after a truth, of which the scent has so long been lost. The Oxford Marbles, which appear to us the best authority to follow, tell us, in express terms, that he was the son of Dendeneus of Lesbos, and that he flourished in the 381st year of these records; which nearly answers to the 27th olympiad, and 671st year B. C. The Marbles inform us likewise, that "he taught the notes, or airs, of the lyre and flute, which he performed himself upon this last instrument, in concert with other players on the flute." Several writers tell us that he added three strings to the lyre, which before his time had but four; and in confirmation of this, Euclid and Strabo quote two verses, which they attribute to Terpander himself.

"The tetrachord's restraint we now despise,
The seven-stringed lyre a nobler strain supplies."

If the hymn to Mercury, which is ascribed to Homer, and in which the seven-stringed lyre is mentioned, be genuine, it robs Terpander of this glory. The learned, however, have great doubts concerning its authenticity. But if the lyre had been before his time furnished with seven strings in other parts of Greece, it seems as if Terpander was the first who played upon them at Lacedæmon. The Marbles tell us that the people were offended by his innovations. The Spartan discipline had deprived them of all their natural feelings; they were rendered machines; and whether Terpander disturbed the springs by which they used to be governed, or tried to work upon them by new ones, there was an equal chance of giving offence. The *new strings*, or *new melodies*, and *new rhythms*, upon the old strings, must have been as intolerable to a Lacedæmonian audience, at first hearing, as an organ, and cheerful music would have been, to a Scots congregation some years ago, or would be at a Quaker's meeting now. "It is not at all surprising," says Alcibiades, "that the Lacedæmonians seem fearless of death in the day of battle, since death would free them from those laws which make them so wretched."

Plutarch, in his "Lacænic Institutions," informs us, that Terpander was fined by the ephori for his innovations. However, in his "Dialogue on Music," he likewise tells us, that the same musician appeased a sedition at Sparta, among the same people, by the persuasive strains which he sung and played to them on that occasion. There seems no other way of reconciling these two accounts, than by supposing that he had, by degrees, refined the public taste, or depraved his own to the level of his hearers.

Among the many signal services which Terpander is said to have done to music, none was of more importance than the notation that is ascribed to him for ascertaining and preserving melody, which was before traditional, and wholly dependent on memory. The invention, however, of musical characters has been attributed by Alypius and Gaudenius, two Greek writers on music, and, upon their authority, by Boethius, to Pythagoras, who flourished full two centuries after Terpander. It will be necessary therefore to tell the reader upon what grounds this useful discovery has been bestowed upon him.

Plutarch, from Heraclides of Pontus, assures us that Terpander, the inventor of notes for the cithara, in hexameter verse, "set them to music," as well as the verses of Homer, in order to sing them at the public games. And Clemeas Alexandrinus, in telling us that this musician wrote the laws of Lycurgus in verse, and "set them to music," makes use of the same expression as Plutarch, which seems clearly to imply a *written melody*. See *Musical GAMES*.

TERPELING, in *Geography*, a town of Thibet; 8 miles S.W. of Painom Jeung.

TERPENTARIA, in *Botany*, a name used by some authors for the betonica aquatica, or great water-figwort, called *water-betony*.

TERPILLUS, in *Ancient Geography*, a town of Macedonia, in Mygdonia. Ptolemy.

TERPONUS, a town of Illyria, belonging to the Japodes, of which Cæsar took possession, according to Appian.

TERPSICHORE, the *Jovial*, as her name imports, in *Mythology*, the name of one of the nine *Muses*, (which see.) This muse is represented on medals and other monuments, by the flutes which she holds in her hands.

TERRA, in *Geography*.

TERRA, in *Chemistry*.

TERRA, in *Natural History*.

} See EARTH.

TERRA *Alana*, a name given to the yellowish-white tripoli.

TERRA *Adamica*, a name given to the alkaline red mould. See ADAMIC Earth.

TERRA *Armenia*. See BOLE.

TERRA *de Baira*, the name given by some to an earth of a white colour, found about Baira, near Palermo.

It is esteemed a very great medicine in the cure of malignant fevers, and in the stopping of hæmorrhages of all kinds. The powder of it is commonly sold in Italy under the name of Claramont-powder; a name it obtained from a person who first found out its virtues, and communicated them to the world in a treatise expressly written on the subject. Boccone, Mus. de Fific.

TERRA *Cariofa*. See TRIPOLI.

TERRA, *Chio*, in the *Materia Medica of the Ancients*, an earth of the marle kind, found in the island of Chio, and given internally as an astringent; but its chief use among them was as a cosmetic, the ladies esteeming it the finest of all things for clearing the skin, and smoothing wrinkles. What title it has to these qualities the world has not of late ages inquired into; but the substance is still in being, and to be had in any quantities from the same place. And the descriptions Dioscorides and Galen have left us of it are so accurate, that there is not the least room to doubt but that the earth now found there, was the very kind they used. It is a dense compacted earth, yet very soft, and of a texture easily disunited and broken by water.

TERRA *Cilicia*. See CILICIA.

TERRA *Cimolia*. See CIMOLITE.

TERRA *Cimolia Purpurascens*. See SOAP-Earth.

TERRA *Coloniensis*. See COLOGNE-Earth.

TERRA *Damnaia*. See CAPUT MORTUUM.

TERRA *Foliata Tartari*, foliated earth of tartar, is a name improperly given to a neutral acetous salt, with a basis of fixed vegetable alkali; or to a combination of the acid of vinegar, saturated with the alkali of tartar, or of other vegetable matter. This salt has also been called *regenerated tartar*, because the alkali of tartar is united with an acid, which is in some respects similar to the acid of tartar, but is in others very different.

The terra foliata is made by pouring upon a quantity of alkaline salt of tartar, in a glass cucurbit, a sufficient quantity of good distilled vinegar, at different times, to saturate all the alkali, or even a little more than is necessary for that purpose, till the effervescence entirely ceases. This saturated liquor is to be filtrated and evaporated to dryness, with a gentle heat. The dry salt thus obtained is to be dissolved in spirit of wine, and the solution again evaporated to dryness; by which means a salt is obtained more or less white, of a silky appearance, and composed of small scales or leaves, whence it has been called *foliata*. When the salt is dried, and while it is hot, it must be shut up in a well-closed bottle, because it quickly becomes moist by exposure to air.

When distilled vinegar is poured upon salt of tartar, little or no effervescence is made at first, because a part of the alkaline salt employed is generally caustic, or deprived of its gas, which part unites with the acid preferably to the mild part of the alkali, and absorbs any gas that is extricated from the latter part; and, therefore, till all the caustic part of the alkali be nearly saturated, little or no effervescence can happen. But when more vinegar is added, the effervescence becomes so considerable, that some of the liquor will, without care, flow over the vessel. This effervescence is occasioned by a large quantity of air that is disengaged during the saturation. When the saturation is advanced to a cer-

tain degree, the effervescence diminishes; but the combination of the last portions of the acid and alkali may be facilitated by frequently agitating the liquor, which will renew the effervescence. The taste of the foliated earth is sharp, pungent, a little caustic, and partaking at the same time of the taste of vinegar and that of fixed alkali. It is soluble in spirit of wine, and may be decomposed merely by the action of fire, and from it may be obtained by distillation, a very penetrating and concentrated radical vinegar. It is little used except in medicine. Macquer's Chem. Dict.

Preparations of this kind are given in doses of ten or twenty grains as mild aperients, and to a drachm or two as purgatives and diuretics. Lewis.

TERRA *Goltbergenfis*. See GOLTBERGENSIS Terra.

TERRA *Japonica*. See JAPAN Earth, and CATECHU.

TERRA *Lemnia*. See LEMNIAN Earth.

TERRA *Lignicensis*. See LIGNICENSIS Terra.

TERRA *Livonica*. See LIVONICA Terra.

TERRA *Melia*. See MELIA Terra.

TERRA *Melitenfis*. See MELITENSIS Terra.

TERRA *Merita*, in the *Materia Medica*, a name given by some authors to the curcuma, or turmeric-root.

It is from a false pronunciation of this name, *terri merit*, that the English turmeric has its origin.

TERRA *Miscella*. See THRAUSTOMICHTES.

TERRA *Noceriana*. See NOCERIANA.

TERRA *Samia*. See SAMIA Terra.

TERRA *Seleneusiaca*. See SELENEUSIACA.

TERRA *Sigillata*. See SIGILLATA.

TERRA *Sigillata Magni Ducis*. See ETRUSCA Terra.

TERRA *Sigillata Fusca*, a bole of a beautiful brown colour, found in Germany, England, and America.

It is of a dense texture, makes no fermentation with the strongest acids, and if thrown into water, it soon separates into a number of thin flakes.

The Germans give it in fluxes and malignant fevers, being an excellent astringent, and worthy to be introduced into our shops.

TERRA *Silefiaca*, *Silesian Earth*, a fine astringent bole, called by some authors *axungia folis*.

It is very heavy, of a firm compact texture, and in colour of a brownish-yellow. It breaks easily between the fingers, and does not stain the hands, is naturally of a smooth surface, and is readily diffusible in water, and melts freely into a butter-like substance in the mouth; it leaves no grittiness between the teeth, and does not ferment with acid menstrua. These are the characters by which it is known from all other earths of a like colour; it is found in the perpendicular fissures of rocks near the gold-mines at Strigonium, in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is, however that be, a good astringent, and better than most of the boles in use. Hill.

The terra Silefiaca is also called *terra sigillata Strigoniensis*.

TERRA *Sinopica*. See SINOPICA Terra.

TERRA *Solis*, a name given by the German naturalists to a kind of black spongy earth, somewhat approaching to the nature of that English black earth which we call *kellow*, but containing gold. It is not properly an ore of gold, but is an earth into which some small particles of gold have been washed from some other place, and there detained. A good microscope will discover these particles in the richer pieces of the earth, and they are bright and pure, though very small: the earth is found in fissures of the other strata, not in any beds or strata of itself. It is not to be had in any great quantity, nor does it contain any large portion of gold.

TERRA *Strigoniensis*. See STRIGONIENSIS Terra.

TERRA Turcica. See *TURCICA Terra.*

TERRA Virgine Aurea, in *Natural History*, the name of a medicinal earth, mentioned by Boccone.

It is found at a place called Sancto Paolo, in the state of Modena; and is thence sent to Venice, and many other places, where it is esteemed a very famous medicine.

Its great use is in hæmorrhages of all kinds; but it is also given with success in malignant fevers. Boccone, *Mus. de Fific.*

TERRA Viridis. See *TERRE Verte.*

TERRA Umbri. See *UMBER.*

TERRA Zeica, a name given to the alkaline red mould, called also Adamic earth.

TERRA Peita, in *Law.* See *SUMMONS.*

TERRA, in our *Ancient Law-Books*, occurs in the sense of land, or ground, joined with divers additions; as,

Terra Normannorum, the lands of such Norman noblemen as were forfeited to the crown, by the owners taking part with the French king against Henry III. *Terra frusca*, such land as had not been lately ploughed. *Terra gilliflorata*, land held by the tenure of paying a gilliflower yearly. *Terra vestita*, land sown with corn, and the crop still remaining thereon. *Terra testamentalis*, land held free from feudal services, and devisable by will. *Terra culta*, land that is tilled and manured, in contradistinction to *terra inculta*. *Terra affirmata*, land let out to farm. *Terra dominica*, or *indominica*, demesne land of a manor. *Terra hydatica*, was land subject to the payment of hydage. *Terra lucrabilis*, land that may be gained from the sea, or enclosed out of a waste or common to particular uses. *Terra wainabilis*, tillage-land. *Terra warella*, fallow-land. *Terra boscalis*, wood-land, &c.

TERRA Extendenda, is a writ directed to the escheator, &c. ordering him to inquire and find out the true yearly value of any land, &c. by the oath of twelve men, and certify the extent in chancery.

TERRA or *Tierra Australis del Espiritu Santo*, in *Geography*, an island in the South Pacific ocean, and the most westerly as well as the largest of those called *New Hebrides*: discovered by Quiros, and visited by captain Cook in the year 1774; 22 leagues long, 60 miles in circuit, and 12 in breadth. The land of it, especially the west side, is exceedingly high and mountainous: and in many places the hills rise directly from the sea. Except the cliffs and beaches, every other part is covered with wood, or laid out in plantations. Besides the bays of St. Philip and St. Jago, the isles which lie along the south and east coast cannot, in the opinion of captain Cook, fail of forming some good bays or harbours. S. lat. 14° 40' to 15° 40'. E. long. 166 45' to 167° 32'.

TERRA Firma is sometimes used for a continent, in contradistinction to islands.

Thus Asia, the Indies, and South America, are usually distinguished into terra firmas and islands.

TERRA Firma, in a more restricted sense, denotes an immense extent of country under the authority and government, direct or indirect, of the crown of Spain, comprehending several extensive provinces, and three audiences, fixed at Panama, Quito, and Santa Fé de Bogota: the large provinces are Terra Firma Proper, Popayan, Quito, and New Granada, all of which are again subdivided into several smaller provinces or jurisdictions.

TERRA Firma, or *Tierra Firmé*, in a still more confined sense, comprises three districts in the vicerealty of New Granada, viz. Darien, Panama or Tierra Firmé Proper, and Veragua.

TERRA Firma, or *Tierra Firmé*, *Proper.* See *PANAMA.*

TERRA del Fuego, a large island, separated from the southern extremity of America by a narrow sea, called the "Straits of Magellan:" so named from the volcanoes observed on it. Capt. Cook was the first navigator who had the honour, from a series of the most satisfactory observations, beginning at the W. entrance of the Straits of Magellan, and carried on with unwearied diligence round this island, through the strait of Le Maire, to construct a chart of the southern extremity of America. The south-west coast of Terra del Fuego, says this distinguished navigator (Second Voyage, vol. ii. p. 199, &c.) "with respect to inlets, islands, &c. may be compared to the coast of Norway; for I doubt if there be an extent of three leagues where there is not an inlet or harbour, which will receive and shelter the largest shipping. The worst is, that till these inlets are better known, one has, as it were, to fish for anchorage. There are several lurking rocks on the coast; but happily none of them lie far from land, the approach to which may be known by sounding, supposing the weather so obscure that you cannot see it. For to judge of the whole by the parts we have founded, it is more than probable that there are soundings all along the coast, and for several leagues out to sea. Upon the whole, it is by no means the dangerous coast it has been represented. The currents between Cape Desade and Cape Horn set from west to east, that is, in the same direction as the coast; but they are by no means considerable. To the east of the cape, their strength is much increased, and their direction is north-east to Staten Land. They are rapid in Strait le Maire, and along the south coast of Staten Land, and set like a torrent round Cape St. John, where they take a north-west direction, and continue to run very strong both within and without New Year's Isles. While we lay at anchor within this island, I observed that the current was strongest during the flood; and that on the ebb its strength was so much impaired, that the ship would sometimes ride head to wind, when it was at west and west-north-west. This is only to be understood of the place where the ship lay at anchor; for at the very time we had a strong current setting to the westward, Mr. Gilbert found one of equal strength near the coast of Staten Land setting to the eastward; though probably this was an eddy current or tide."

Most writers who have mentioned the island of Terra del Fuego, describe it as destitute of wood, and covered with snow. The latter circumstance may occur (see Hawkesworth's Voyages of Cook, &c. vol. ii.) in winter. And by those who saw it at that season, it might be conceived to be without wood. Lord Anson was there in the beginning of March, answering to our September; but Capt. Cook was there in the beginning of January, corresponding to our July; and thus we may account for their different statements. We fell in with it, says Cook, about 21 leagues W. of the strait of Le Maire, and trees were visible with glasses; and though upon approaching it patches of snow were discoverable, yet the sides of the hills and the sea-coast appeared to be covered with a beautiful verdure. The hills are lofty, but not mountainous, though their summits are quite naked. The soil in the vallies is rich, and of a considerable depth; and at the foot of almost every hill there is a brook, the water of which has a reddish hue, but it is not ill-tasted. The most remarkable land in Terra del Fuego is a hill, in the form of a sugar-loaf, which stands on the W. side, not far from the sea; and the three hills, called the "Three Brothers," about nine miles W. of Cape St. Diego, the low point that forms the entrance of the strait of Le Maire. (See *Le MAIRE.*) In his

his second voyage, Capt. Cook, desirous of coasting the S. side of Terra del Fuego, round Cape Horn, to the strait of Le Maire, reached the W. coast of the island Dec. 17, 1774, and having continued to range it till the 20th, came to an anchor in a place which he called "Christmas Sound." Through the whole course of his navigations, he had never seen so desolate a coast. It seems to be entirely composed of rocky mountains, without the least appearance of vegetation. These mountains terminate in horrible precipices, the craggy summits of which spire up to a vast height; so that scarcely any thing in nature can appear with a more barren and savage aspect than the whole of the country. But barren and dreary as the land is about Christmas Sound, it was not wholly destitute of accommodations. Near every harbour our navigator found fresh water, and wood for fuel. The country abounds likewise with wild fowl, and particularly with geese: which, with their Madeira wine, enabled them to keep a cheerful Christmas. The inhabitants of Terra del Fuego were found by Capt. Cook to be of the same nation which he had formerly seen in Success Bay, and the same with those denominated by M. de Bougainville "Pecharas." They are a little, ugly, half-starved, beardless race, and go almost naked: but it is their own fault that they are not better clad, as nature has furnished them with ample materials for that purpose. By lining their seal-skin cloaks with the skins and feathers of aquatic birds, by making the cloaks themselves larger, and by applying the same materials to different parts of clothing, they might render their dresses much more warm and comfortable. But while they are doomed to exist in one of the most inhospitable climates on the globe, they have not sagacity enough to avail themselves of those means of adding to the conveniences of life, which Providence has put into their power. The captain, after having witnessed many varieties of the human race, pronounces the Pecharas to be the most wretched. Those on the S. are said to be uncivilized, treacherous, and barbarous; while those on the opposite side are represented as simple, affable, and perfectly harmless. The tents which they inhabit are made of poles, disposed in a conical form, covered with skins, or the bark or leaves of trees. The country, though barren, abounds with a variety of unknown plants, for exciting the curiosity of the botanist. The extent of Terra del Fuego, and consequently of the straits of Magellan, was ascertained by Cook to be less than had been laid down by the generality of navigators: nor was the coast, upon the whole, found to be so dangerous as it has been represented: the winter was also remarkably temperate. The sea-lions and sea-bears, the shags and penguins on the coast, are abundant, and intermix, like domestic cattle and poultry in a farm-yard, without attempting to molest one another. Eagles and vultures were feated on the hills among the shags in perfect tranquillity. Sir Joseph Banks, Dr. Solander, and some others, landed here in the month of January 1769, which is the time of summer in that part of the globe, notwithstanding which, two of the company fell a sacrifice only by sleeping one night, and Dr. Solander himself hardly escaped. S. lat. $52^{\circ} 30'$ to $55^{\circ} 35'$. W. long. $51^{\circ} 20'$ to 58° .

TERRA *Magellanica*. See PATAGONIA.

TERRA *Niwa*, a bay in Hudson's Bay. N. lat. $62^{\circ} 4'$. W. long. 67° .

TERRA *dos Fumos*, a tract of country on the S.E. of Africa, N. of Natal.

TERRA *Nova*, a sea-port town of Sicily, in the valley of Noto, situated in a gulf or bay of the Mediterranean, founded about the middle of the 13th century, by the em-

peror Frederick II. near the site of the ancient Gela. The number of inhabitants is about 700; 50 miles W. of Syracuse. N. lat. 37° . E. long. $14^{\circ} 10'$.—Alfo, a river of Sicily, which runs into the sea on the S. coast. N. lat. 37° . E. long. $14^{\circ} 10'$.

TERRA *Nuova*, a town of the island of Sardinia, situated in a bay of the Mediterranean, at the bottom of which is the harbour, built on the ruins of Civita, an ancient episcopal town; 57 miles E.N.E. of Sassari. N. lat. $40^{\circ} 52'$. E. long. $9^{\circ} 40'$.—Alfo, a town of Etruria; 14 miles N.W. of Arezzo.

TERRA *del Palucci*, a town of Sicily, in the valley of Mazara, on the site of the ancient Pelinus.

TERRA *Vecchia*, a town of Naples, in Calabria Citra; 2 miles S. of Cariati Nuovo.

TERRA *à Terra*. Gallies and other vessels are said to go terra à terra, when they never go far from the coast.

The phrase is also applied, in the manege, to horses that make neither curvets nor balotades, but run smoothly on the ground in a pressed gallop, only making little leaps or risings with the fore-feet.

The gallop is the foundation of the terra à terra, for in these two motions the principle of the action is the same, since the terra à terra is only a shortened gallop with the croupe in, and the haunches following in a close and quick time. And as the mezar is higher than the action of terra à terra, and lower than that of curvets, it may be concluded that the terra à terra is the foundation of the mezar, as well as of curvets.

In the terra à terra the horse should be more together than in the gallop, that he may mark his time and cadence more distinctly; although in a true terra à terra there are no times to be marked, for it is rather a gliding of the haunches, which comes from the natural springs in the limbs of a horse.

When a horse works terra à terra, he always ought, as in the gallop, to lead with the legs that are within the volte, his two fore-feet being in the air, and the moment they are coming down, his two hind feet following. The action of the gallop is always one, two, three, and four; the terra à terra is performed upon two lines and in two times.

To work a horse terra à terra upon large circles, take care to keep the body straight, steady, and true in the saddle, without leaning to one side or the other. Lean upon the outward stirrup, and keep the outward leg nearer the side of the horse than the other leg, taking care to do it so as not to be perceived. If you go to the right, keep your bridle-hand a little on the outside of the horse's neck, turning your little finger up without turning your nails at the same time; although, if need be, you must turn them in order to make the inner rein work which passes over the little finger. Keep your arms and elbows to your hips; by this means you will assure and confine your hand, which ought to accompany, and, as it were, run along the line of the circle with the horse. Berenger's Art of Horsemanship, vol. ii. c. 17.

The term is also applied by the French to dancers, who cut no capers, nor scarcely quit the ground.

And hence, also, it is figuratively applied to authors, whose style is low and creeping.

TERRACE, in Gardening, is a sort of raised bank of earth, &c. regularly formed in an oblong manner to any length, broad enough to admit of a spacious level walk at top, and elevated considerably above the level of the general surface; having the sides uniformly sloped, and laid with grafs, and the top formed into a flat or level, sufficiently broad

broad for a grass or gravel walk of proportionable width; designed in gardens as a high, airy walk, to command a better prospect of the adjacent places around, within and without the garden occasionally, as well as to enjoy the fresh air in summer more freely. In the former style of laying out gardens, it was considered as very ornamental, but is at present much in disuse.

It may be remarked, that the height of a terrace-walk may be more or less, as the situation admits, as from one foot to one or two yards, or even three or four yards or more in particular situations; and where there is plenty of earthy materials, rubbish, &c. to form it, allowing breadth in proportion, from five to ten or twenty feet or more, and extended to any length required. They are sometimes formed on some naturally high rising ground, to save as much trouble as possible in bringing stuff from a distance; and sometimes raised wholly of forced materials. But the situation for a terrace may be varied as the natural situation of the place may require.

In respect to form, they should always be broader at the base than the top, and extend lengthways to any distance required; having the sides regularly sloped, of more or less acclivity, as the width, height, and situation admit. Sometimes both sides are sloped, and sometimes only one side, the other perpendicular, and faced with a substantial wall, &c. or formed against the side of a hill, or some naturally rising ground, being finished always broad enough at top to admit of a proper walk. In some naturally elevated situations, terraces are sometimes formed one above another, in two or more ranges, each having its separate side slopes, and elevated walk; in all of which the slopes are to be neatly laid with grass, and the walk at top occasionally of grass or gravel.

The entrances leading to terrace-walks were formerly sometimes formed by an easy acclivity of a grass or gravelled slope, and sometimes by a grand flight of stone steps. Where a rising ground of considerable elevation naturally presents itself in a proper situation, it is an eligible opportunity for forming a terrace with the least expence and trouble, on account of its not requiring the addition of so much earth and rubbish, as when raised entirely on a perfect level, wholly of made earth. Where there are any excavations of ground intended to form ha-has, pieces of water, &c. the excavated earth may be employed in forming terraces, &c.

In the business of forming a terrace, the base must be staked out wider than the intended width at top for the walk, in order to admit of the ascent of slopes being moderate. And the whole of the made earth and rubbish must be well rammed and rolled down from time to time as it is applied, in order to render the whole equally firm, that it may not settle irregularly after being finished. The slopes may either be laid with turf, or sown with grass-seeds; but the first is much the best method, where it can be employed. See *GRASS Ground*.

Terraces are now but little attended to, and, of course, but seldom employed in modern ornamental gardening, as they are mostly considered as having a too stiff and formal appearance, and as not constituting that sort of neatness and tasteful elegance, which is so much esteemed and admired at present in all sorts of works of the garden kind.

TERRACE, Counter, is a terrace raised over another to join two grounds, or raise a parterre.

TERRACE is also applied to the roofs of houses that are flat, and on which one may walk; as also to balconies that project.

The terrace is properly the covering of a building which
Vol. XXXV.

is in platform; as that of the peristyle of the Louvre, or that of the observatory, paved with flint and mortar. All the buildings of the Oriental nations are covered with terraces, to take the fresh air on, and even to lie on. See *PAVEMENT of Terrace*.

TERRACE, or Terras, used for mortar. See *TARRAGE*.

TERRACINA, in *Geography*, a town of the Pope-dome, in the Campagna di Roma, situated in a very fruitful but marshy country, which makes the air unwholesome. This town was anciently the capital of the Volsci, and named Anxur. The Greeks called it Trachyna, corrupted into Terracina. In the year of Rome 348, it was taken and plundered by Fabius Ambustus; and in 424 was made a Roman colony. Being built on a rock, in the reign of Tiberius 20,000 persons were killed by the fall of a theatre. It is now a poor place. It had once a harbour: but that is choked up; near Terracina are considerable fragments of the Via Appia, made from Rome to Capua by Appius Claudius Coccus, and begun by him while censor, in the year of Rome 440: this road was paved with hard stone of various sizes, but uniformly twelve inches in thickness; and was wide enough for two carriages; 47 miles S.E. of Rome. Near this place was a fountain of Neptune, the water of which was said to be fatal.

TERRADEGLIAS, or TERRADELLAS, DOMENICO, in *Biography*, a native of Barcelona, in Spain; but who went early into Italy, where he studied music at Naples under Durante, as an accomplishment; but was reduced, by accidents in his family, to practise it as a profession.

He began to flourish about 1739, when he composed the opera of "Astarto," and part of "Romolo," in conjunction with Latilla, for the Teatro delle Dame, at Rome.

In the latter end of the year 1746 he came to England, where he composed two operas, "Mithridates" and "Bellerophon." But unfortunately for the composer, none of the fingers of this time stood high in the favour of the public. Yet his opera of "Mithridates," we well remember, received much applause, as music, distinct from what was given to the performers. And his compositions, when executed in Italy by fingers of the first class, acquired him great reputation.

Besides the favourite songs in the two operas just mentioned, which are printed by Walsh, Terradellas himself, while he was in England, published a collection of twelve Italian airs and duets in score, which he dedicated to lady Chesterfield. In these he seems less masterly and original than in his other productions that have come to our knowledge. In the songs he composed for Reginelli, a very learned singer in ruin, we find boldness and force, as well as pathos. And some *arie di bravura* of his composition, for the celebrated tenor singer Babbi, at Rome, abound with fire and spirit. If his productions are compared with those of his contemporaries, his writings, in general, must be allowed to have great merit; though his passages now seem old and common. This composer having spent his youth in Catalonia, was not regularly initiated into the mysteries of counterpoint in any Neapolitan conservatorio, having been placed under Durante, for a short time, only as a private scholar; and we think we can sometimes discover in his scores, through all his genius and elegance of style, a want of study and harmonic erudition.

Terradellas was remarkable, not only for attending, in every situation of the finger, to the spirit of the drama which he had to compose, but for giving good music to bad fingers, and not *under-writing*, as Mr. Bayes calls it; the inferior parts of his theatrical pieces. Indeed, it has always appeared to us, that an exquisite finger who can command

attention by the mere tone of his voice, and who requires only a *canevas*, or outline, to colour at his pleasure, is in less want of artificial and captivating composition, than an ordinary singer, who is neither possessed of voice nor taste sufficient to interest the audience. And Terradellas seems to have written all his songs for performers of abilities; for his airs are never made easy and trivial in order to spare the singer. Jomelli's pen always flowed with this spirit; for he never rejected a passage that presented itself, because it would be difficult and troublesome in the execution; but this freedom of style, twenty years ago, might be more safely practised than at present: for it is well known, that a company of singers is now reckoned good, in Italy, if the two first performers are excellent; and an opera is sure to please if two or three airs and a duet deserve attention; the audience neither expecting nor attending to any thing else. And the managers, who find this custom very convenient, take care not to interrupt play or conversation by the useless and impertinent talents of the under-singers; so that performers of the second or third class are generally below mediocrity.

He died at Rome in 1751, of grief and mortification, for the failure of an opera which he had composed with more care and hopes of success than usual.

TERRÆ *Ager, Amittere, Aratrum, Aratura, Denariatus, Legem, Lex, Librata, Obolata, Quadrantata, Quadrugata, Trinoda, and Uncia.* See the several articles.

TERRÆ *Filius, son of the earth*, a student in the university of Oxford, formerly appointed in public acts to make jesting and satirical speeches against the members of them, and to tax them with any growing corruption, &c.

TERRÆ *Oleum.* See OIL of the Earth.

TERRÆJEBIN. See TERENJABIN.

TERRAGE, or TERRAGIUM, anciently signified a service, in which a tenant or vassal was bound to his lord, to plough and reap the ground for him.

Others will have it to have been money paid for digging or breaking the ground in fairs and markets.

"*Quieti sint de thelonio, pavagio, passagio, lastagio, tallagio, carvagio, prisagio, et terragio.*"

TERRAIGNOL, in the *Manege*, a horse that cleaves to the ground, that cannot be made light upon the hand, that cannot be put upon his haunches, that raises his fore-quarters with difficulty, that is charged with shoulders, and, in general, one whose motions are all short, and too near the ground.

TERRAIN, is the manege ground, upon which the horse makes his pisse, or tread.

TERRANTONA, in *Geography*, a town of Spain, in Aragon; 8 miles S.E. of Ainsa.

TERRANUOVA, a town of Naples, in Calabria Citra; 9 miles N. of Bisignano.

TERRAON, or TORRAON, O, a town of Portugal, in Alentejo; 24 miles N.W. of Beja.

TERRAPOUR, a town of Hindoostan, in Baglana; 32 miles N. of Basdeen.

TERRAQUEOUS, compounded of *terra* and *aqua*, earth and water, an epithet given to our globe or earth, considered as consisting of land and water, which together constitute one mass.

Some philosophers, particularly Dr. Burnet, charge the frame and fashion of the terraqueous globe as rude, unartful, and disorderly, and conclude it highly absurd to suppose it came thus out of the hands of the Creator; and, therefore, have recourse to the deluge for making it thus.

But others can perceive much art and conveniency, even

in this apparent disorder: Dr. Derham particularly observes; that the distribution of land and water is admirable; the one being laid over the other so skilfully through all the world, that there is a just equipoise or balance of the whole globe. Thus the Northern ocean balances the Southern, and the American continent is a counterpoise to the European, African, and Asiatic.

And what some may object, that the waters occupy too great a part of the globe, which they imagine would be of more use if it were dry land, he obviates, by shewing that this would deprive the world of a due quantity of vapours and rain; for if the cavities which contain the sea and other waters were deeper, though the quantity of water were the same, and only the surface less and narrower, the evaporations would be so much the less, inasmuch as they are made from the surface, and consequently are in proportion to it.

TERRAR. See TERRIER.

TERRAS. See TERRACE and PAVEMENT.

TERRAS, *Marble.* See MARBLE.

TERRASSE, LA, in *Geography*, a town of France, in the department of the Here; 13 miles N.N.E. of Grenoble.

TERRASSON, JOHN, *Abbé*, in *Biography*, a man of letters, was born at Lyons in 1670, and sent by his father, who was a very religious man, to the house of the Oratory in Paris; but the son, quitting this congregation, and disappointing his father's views, incurred his resentment, so that he was left with a very moderate pittance. However, the abbé Bignon procured him admission into the Academy of Sciences in 1707: he soon became a member; and in 1721, professor of Greek and Latin in the Royal College. Under the famous system of Law, he acquired temporary opulence, but was soon again reduced to penurious circumstances. He then retired from the world, studying and exercising that philosophy which raised him above it. He died at Paris in 1750, at the age of 80 years. His works are, "A Critical Dissertation on Homer's Iliad;" "Reflections in favour of Law's System;" "Sethos," a moral romance; "A Translation of Diodorus Siculus," 7 vols. 12mo. with preface, notes, and fragments. It was one of Terrasson's sayings, "What is the most credulous of all things? Ignorance. What is the most incredulous? Ignorance."

Andrew Terrasson, the elder brother of the former, a priest of the Oratory, was a celebrated preacher, and died at Paris in 1723. His "Sermons," in 4 vols. 12mo. were published in 1726, and reprinted in 1736.

Gaspard Terrasson, another brother, and priest of the Oratory, was more celebrated as a preacher than the former, and officiated at Paris during five years. Having incurred persecution, he quitted the pulpit and the congregation of the Oratory. He died at Paris in 1752. His "Sermons," in 4 vols. 12mo. appeared in 1749. His anonymous work, entitled "Lettres sur la Justice Chretienne," was censured by the Sorbonne.

Another person of the same family, viz. Matthew Terrasson, was born at Lyons in 1669, studied the law, and pleaded causes with great reputation. He was for some time an associate in the "Journal des Sçavans," and also censor royal. He died, much esteemed, at Paris, in 1734. A "Collection of his Pleadings, &c." was published in 4to.

The son of the preceding, Anthony Terrasson, was born at Paris in 1705, brought up to the bar, and excelled in jurisprudence. By order of chancellor d'Aguesseau, he composed a "History of Roman Jurisprudence," with a collection of Ancient Contracts, &c. in fol. 1750. In 1760 he was promoted to the chancellorship of Dombes, and died in 1782. He was the author of "Melanges d'Histoire, de

Literature, de Jurisprudence, de Critique, &c." 1768; and of other works. Moreri. Nouv. Dict. Hist. Gen. Biog.

TERRASSON, in *Geography*, a town of France, and seat of a tribunal, in the department of the Dordogne; 18 miles N.E. of Montignac. N. lat. $45^{\circ} 7'$. E. long. $1^{\circ} 23'$.

TERRAUBE, a town of France, in the department of the Gers; 4 miles S.W. of Lectoure.

TERREBONNE, a town of Canada; 12 miles N.N.W. of Montreal.

TERREGLES, a town of Scotland, in the county of Dumfries; 2 miles W. of Dumfries.

TERREL, a town of North Carolina; 30 miles N. of Greenville.

TERRELLA, *μικρογην*, *little earth*, is a magnet turned of a just spherical figure, and placed so as that its poles, equator, &c. do exactly correspond with those of the world.

It was thus first called by Gilbert, as being a just representation of the great magnetic globe we inhabit.

Such a terrella, if nicely poised, and placed in a meridian like a globe, it was supposed, would be turned round like the earth in twenty-four hours by the magnetic particles pervading it; but experience has shewn this to be a mistake.

TERRE-PLEIN, in *Fortification*, the top, platform, or horizontal surface of the rampart, on which the cannon are placed, and the defenders perform their office.

It is thus called as lying level, having only a little slope outwardly to bear the recoil of the cannon.

It is terminated by the parapet on that side towards the champaign; and by the inner talus on that side towards the place. Its breadth is from 24 to 30 feet.

TERRESCHOW, in *Geography*, a town of Bohemia, in the circle of Pilsen; 16 miles N.E. of Pilsen.

TERRESSA, one of the Nicobar islands, about fifteen miles long, and from two to five broad, of an oval form. N. lat. $8^{\circ} 20'$. E. long. $93^{\circ} 36'$.

TERRESTRIAL BIRDS. See BIRDS.

TERRESTRIAL GLOBE. See GLOBE.

TERRESTRIAL LINE. See LINE, *Terrestrial*.

TERRESTRIAL PARADISE. See PARADISE.

TERRESTRIAL ROADS. See ROAD.

TERRE-TENANT, is he who has the actual possession of the land, otherwise called the occupant. See TENANT and OCCUPANT.

Thus a lord of a manor having a freeholder, who letteth out his freehold to another to be occupied, this occupier who has the actual possession is called the *terre-tenant*.

TERRE-VERTE, in the *Colour-Trade*, the name of a green earth much used by painters, both singly for a good standing green, and in mixture with other colours.

The name is French, and signifies *green earth*.

It is an indurated clay, of a deep blueish-green colour, and is found in the earth, not in continued strata or beds, as most of the other earths are, but in large flat masses of different sizes, imbedded in other strata; these break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different sizes. It is of a fine, regular, and even structure, and very hard. It is of an even and glossy surface, very smooth to the touch, and in some degree resembling the morochthus, or French chalk, but adhering firmly to the tongue. It does not stain the hands in touching it; but being drawn along a rough surface, it leaves an even white line, with a greenish cast.

It does not ferment with acids, and is burnt to a dusky brown colour.

It is dug in the island of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been used to be esteemed the best in the world; but

of late there has been some dug in France that equals it. There is also an earth dug on the Mendip hills, in the sinking for coals, which, though wholly unobserved, is nearly, if not wholly, of equal value.

When scraped, and the finer parts separated, it is ready to be made up with oil for the use of the painters, and makes the most true and lasting green of any simple body they use. Hill and Da Costa. See BERG-GRUEN and VERDITER.

TERRIAGULLY, in *Geography*, a town of Bengal; 20 miles N.W. of Rajemal.

TERRIAH, a town of Hindoostan, in Rohilcund; 7 miles S. of Bereilly.

TERRIER, or TERRAR, in our *Ancient Customs*, a collection of acknowledgments of the vassals or tenants of a lordship, containing the rents, services, &c. they owe their lord, and serving as a title or claim for demanding and executing the payment of them.

At present, by terrier we mean no more than a book or roll, in which the several lands, either of a private person, or of a town, college, church, &c. are described. The terrier should contain the number of acres, and the site, boundaries, tenants' names, &c. of each piece or parcel. See DOMESDAY.

TERRIER also denotes the lodge or hole which foxes, badgers, rabbits, &c. dig themselves under ground, and in which they save themselves from the pursuit of the hunters. Hence,

TERRIER, *Terrarius*, is also used for a kind of little hound to hunt those animals, which, like a ferret, creeps into the ground, and by that means affrights and bites them; either tearing them with his teeth, or else haling them by force out of their holes. See DOG and HOUND.

TERRIER, in *Geography*, a town of Africa, on the Senegal; 25 miles S. of Cayar.

TERRIER ROUGE, a town of the island of St. Domingo; 15 miles E.S.E. of Cape Français.

TERRIFICATIO, a word used by some chemical writers to express the coalition of the earthy particles of some bodies after fermentation, or during the time of it.

TERRILS or TYRRELLS *Pasis*, in *Geography*, a post-town of the county of Westmeath, Ireland; 40 miles W. from Dublin.

TERRIMUNGALUM, a town of Hindoostan, in the Carnatic; 25 miles N. of Trichinopoli.

TERRIORE, a town and fortrefs of Hindoostan, in the Carnatic; 24 miles N. of Trichinopoli. N. lat. $11^{\circ} 12'$. E. long. $78^{\circ} 45'$.

TERRIS *Bonis et Catallis, Rebabendis post Purgationem*, in *Law*, a writ for a person to recover his lands, goods, or chattels formerly seized, after having cleared himself of a felony, upon suspicion of which he was convicted, and delivered to his ordinary to be purged.

TERRIS *et Catallis Tenis ultra debitum levatum*, a writ judicial for the restoring lands or goods to a debtor, who is distrained beyond the quantity of the debt. See DISTRESS.

TERRIS *Liberandis*, a writ lying for a man convicted by attain, to bring the record and process before the king, and take a fine for his imprisonment, and deliver him his lands and tenements again, and release him of the strip and waste.

It is also a writ for the delivery of lands to the heir after homage and relief performed; or upon security taken that he shall perform them.

TERRITORY, DISTRICT, the extent or compass of land within the bounds, or belonging to the jurisdiction of any state, city, or other division. See DISTRICT.

It is a maxim, that the church has no territory, *i. e.* it has

TERRITORY.

no temporal jurisdiction; and therefore an ecclesiastical judge cannot arrest any body, not even a priest. It is much in this sense that Cujas says, the church has an auditory, but no territory.

TERRITORY or District of Columbia, in *Geography*, a district of America, ceded to the United States by those of Maryland and Virginia, and established in the year 1800 as the seat of general government. It is beautifully situated on both sides of the Potowmack river, between $38^{\circ} 48'$ and $38^{\circ} 59'$ N. lat., and $7'$ E. and $7'$ W. long. from Washington, the capital. The capital is about $77^{\circ} 0' 22''$ W. from London. It is bounded on the N.E., S.E., and partly N.W., by Maryland; and on the S.W., and partly N.W., by Virginia: in extent it is ten miles square, and contains an area of 6400 square miles. The face of the country is elegantly variegated, and affords a great number of beautiful prospects, of which the Potowmack river is the leading feature. This district affords a variety of streams and springs for watering the city, and for other purposes: its rivers are the Potowmack or Potomac, the Tiber creek, Reedy creek, Rock creek, and Four-mile Run. The soil is thin and sandy, but susceptible of improvement: and the climate is discriminated by a variable spring, a pretty warm summer, an agreeable autumn, and a variable, often very cold, winter.

Morse and Melish. See COLUMBIA and WASHINGTON.

TERRITORY, Illinois, a territory of America, and likely to become soon one of the most important states in the Union, is situated between 37° and $41^{\circ} 45'$ N. lat., and $10^{\circ} 15'$ and $14^{\circ} 15'$ W. long. from Washington city; and is bounded on the N. by the North-west territory, on the S. by Kentucky and Missouri territory, on the E. by Indiana territory, and on the W. by Missouri territory. Its extent from N. to S. is 306 miles, and from E. to W. 210 miles: its area contains 50,000 square miles, or 32,000,000 acres. The aspect of the country is level in the south, and to the north elevated and hilly, but not mountainous. The soil is generally fertile, and produces grain, grass, fruit, flax, and hemp; and in the southern part, cotton. The climate is temperate and agreeable.

TERRITORY, Indiana, an interesting country of America, lately distinguished by this appellation, and now considered as a *nineteenth state*, is situated between $37^{\circ} 45'$ and $41^{\circ} 52'$ N. lat., and $7^{\circ} 40'$ and $10^{\circ} 47'$ W. long. from Washington city; and bounded on the N. by Michigan territory, lake

Michigan, and North-west territory, on the S. by Kentucky, on the E. by Ohio, and on the W. by Illinois territory. Its extent from N. to S. is 240 miles, and from E. to W. 138 miles. Its area contains 34,000 square miles, or 21,760,000 acres. The aspect of the country is hilly, but not mountainous; its scenery rich and variegated; and it abounds with plains and large prairies. Its rivers are the Ohio, Wabash, White-water, Tippecanoe, Illinois, and St. Joseph's: its minerals are coal, lime-stone, free-stone, salt, and silver. The soil is generally rich and fertile; and its produce grain, grass, and fruit, and in the south, cotton. Its climate is temperate, pleasant, and salubrious. Its legislature consists of a house of representatives and senate; the former elected annually, and the latter every three years: they must hold no office of profit when elected. The executive consists of a governor and lieutenant-governor; both elected for three years, and capable of being re-elected once: the former has a compensation of 1000 dollars *per annum*, and the latter two dollars *per day*, while the legislature is in session. Its judiciary administration is composed of a supreme and circuit court: the former composed of three judges, appointed by the governor and senate for seven years; with a salary not exceeding 800 dollars *per annum*: the latter consists of a presiding judge and two associates, who hold courts in each county: the presiding judge appointed by the joint ballot of the legislature for seven years, and the associates elected by the people for seven years: sheriffs, clerks, and justices, are elected by the people; the sheriff for three years, the clerks and justices for seven years. The militia officers are elected by those who are subject to military duty; and all above colonel, by the commissioned officers. A state bank is to be established at the seat of government, with one branch for every three counties; and the branch banks must have 30,000 dollars in specie each, before they begin to act. Involuntary slavery is for ever excluded. The constitution may be amended in 12 years: Corydon is to be the seat of government for nine years. The congress, in erecting the Indiana territory into a state, appropriated, in addition to the school section, an entire township of land for the support of a seminary of learning, and four sections for fixing the seat of the state governor.

TERRITORY, Michigan, a district in America, which, in 1796, was denominated Wayne county, has lately been erected into a territorial government, and organized with the usual offices and powers. It is situated between $41^{\circ} 45'$ and $45^{\circ} 35'$ N. lat., and $5^{\circ} 5'$ and $8^{\circ} 18'$ W. long. from Washington; and is bounded on the N. by the straits of Michilimackinac, on the S. by Ohio and Indiana, on the E. by lakes Huron and St. Clair, and Upper Canada, and

TERRITORY.

on the W. by lake Michigan: Its extent from N. to S. is 234 miles, and from E. to W. 138 miles. Its area contains 27,000 square miles, or 17,280,000 acres. The central part of this territory is high, and from this is a descent in all directions.

The rivers are St. Mary's, Huron, Detroit, Black, Maramee, Grand, Carrion, Raisin, &c. The soil is generally rich and fertile, and produces wheat, oats, barley, rye, corn, potatoes, fruit, &c. The climate is temperate and salubrious; winter lasting from the middle of November to the middle of March.

TERRITORY, *Mississippi*, an improving country of America, which, it is presumed, will be divided into two states, the Tombigby being the boundary. It is situated between 30° 15' and 35° N. lat., and 8° and 14° 32' W. long. from Washington city; and bounded on the N. by Tennessee, on the S. by Louisiana, West Florida, and the gulf of Mexico, on the E. by Georgia, and on the W. by Louisiana and Missouri territory. Its extent from N. to S. is 312 miles, and from E. to W. 324 miles; and its area comprehends 89,000 square miles, or 56,960,000 acres. Its general aspect is, towards the south, level, to the north, elevated and beautifully diversified, and on the north-east are some spurs of the Alleghany mountains. The soil, generally good, and in many places excellent, produces cotton, corn, rice, wheat, rye, oats, some sugar, and indigo. The climate is much commended; the winters being mild, and the summers not warmer than several degrees to the northward.

Melish. See MISSISSIPPI.

TERRITORY, *Missouri*, an improving country of America, which may probably be subdivided into distinct states, is situated between 26° and 49° 37' N. lat., and 12° and 49° 30' W. long.; and bounded on the N. by an unsettled

country, on the S. by Louisiana and the gulf of Mexico, on the E. by Upper Canada, the North-west territory, Illinois territory, Kentucky, Tennessee, Mississippi territory, and Louisiana, on the W. by the Pacific ocean, and on the S.W. by the Spanish internal provinces. Its extent from N. to S. is about 1380 miles, and from E. to W. about 1680 miles; and its area contains 1,580,000 square miles, or 1,011,200,000 acres. The aspect of the country, southward, is level, in many places overflowed by rivers; to the north, elevated, swelling out into large hills; and to the north-west and west, very lofty mountains. The rivers of the territory are the Mississippi, Missouri, Kansas, Grand, Osage, Maramee, St. Francis, White, Arkansaw, Wachitta, Red, Sabine, Moines, Rio Colorado, Rio Bravos de Dios, Rio Guadalupe, Rio del Norte, &c. Its minerals are abundant, particularly lead, the mines of which near St. Genevieve are extensive and valuable. The soil is various in quality, but much of it is rich and fertile; and produces grain, grass, fruit, cotton, and some sugar and indigo. The climate is, in the south, warm, in the middle temperate, to the north and west cold; on the Pacific ocean temperate.

TERRITORY, *North-West*, an extensive territory of America, not yet organized into a regular government, is situated between 41° 45' and 49° 37' N. lat., and 7° and 18° 50' W. long. from Washington city; and bounded on the N. by Upper Canada and lake Superior, on the S. by Indiana and Illinois territory, on the E. by Upper Canada and lake Michigan, on the W. and S.W. by Mississippi river, which divides it from the Missouri territory. Its extent from N. to S. is about 360 miles, and from E. to W. 456 miles; and its area contains about 147,000 square miles, or 94,080,000 acres. The face of the country is generally undulating, in some places hilly, but not mountainous. Its rivers are the Mississippi, Ouifconfin, Fox, Mononomie, Chippeway, &c. The soil is mostly excellent; and the climate, towards the south, is pleasant, and to the north, cold. Few settlements have yet been made in this extensive region, and the inhabitants were not included in the last census. Melish.

TERRITORY of *Orleans*. See LOUISIANA, ORLEANS, and UNITED STATES.

TERROR. The effect of terror, or of sudden frights, in diseases, is often very great.

It is generally observed, that people who are most afraid of the plague in time of contagion, catch the infection soonest; and that those who are most terrified and disheartened at first in the disease, generally die of it. It is indeed uncertain, whether this be attributed to the terror, or whether the terror itself, as a consequence of dejection of spirits, be not merely a symptom of the disease. Kerkring, Spicileg. Anat.

Sudden frights, in acute diseases, have evidently killed many,

many, by the agitation into which they have thrown the spirits, already too much disorderd. We have also accounts of persons absolutely killed by terrors, when in perfect health at the time of receiving the shock from them: people ordered to be executed, but with private orders for a reprieve, have expired at the block without a wound.

The general effects of terror are a contraction of the small vessels, and a repulsion of the blood in the large and internal ones; hence proceed the suppression of perspiration, the general oppression, trembling, and anguish of heart and lungs overcharged with blood, &c.

When a person is affected with terror, the principal endeavour should be to restore the circulation to its due order, to promote perspiration, and to allay the agitation of the patient. For these purposes he may drink a little warm liquor, as chamomile tea, &c.; the feet and legs may be put into warm water, the legs rubbed, and the chamomile tea repeated every six or eight minutes; and when the skin is warm, and there is a tendency to perspiration, sleep may be promoted by a gentle opiate.

TERRYA, in *Geography*, a town of Bengal; 30 miles S. of Beyhar.

TERSA, a small river of Russia, which runs into the Medveditsa, in the country of the Cossacs. N. lat. 50° 30'. E. long. 44° 34'.

TERSCHUEREN, a town of Guelderland; 7 miles E. of Amersfort.

TERSEKAN, a river of Russia, which runs into the Ischim, N. lat. 52° 50'. E. long. 67° 34'.

TERSCHIZ. See TURSHISH.

TERSION, TERSIO, formed of *tero*, I wear, the act of wiping or rubbing a thing. See ABRASION.

TERTA, in *Ancient Geography*, a town situated, according to Ptolemy, in the interior of Thrace, between Sardica and Philippolis.

TERTHRON, a word properly signifying the extreme part of the sail-yard in shipping. Hippocrates uses it in a metaphorical sense, to express the extremity of a disease.

TERTIAN, in *Medicine*, a species of intermitting fever, of which the similar paroxysms occur at an interval of about forty-eight hours. See FEVER.

TERTIAN is also an old measure, containing eighty-four gallons, so called because it is the third part of a tun. 1 R. III. c. 13. 2 H. VI. c. 11.

TERTIANARIA, in *Botany*, a name given by some authors to the scutellaria, or hooded willow-herb. J. Bauhin, vol. iii. p. 435.

TERTIARY CANONS. See CANONS.

TERTIAS, a word used very frequently in the writings of physicians, with the addition of *ad*; but it is capable of a double signification. *Ad tertias* is often used to express how far the liquor is to be boiled away in the medical decoctions; yet it may in this case signify either the boiling to two-thirds, or to one-third part, of the whole. The more usual sense, however, is to boil away one-third part of the original liquor; and in the same manner to fill a vessel *ad tertias*, does not signify to fill a vessel one-third part full, but two-thirds, leaving only one empty.

TERTIATE, in *Gunnery*. To *tertiate* a great gun, is to examine the thickness of the metal at the muzzle, whereby to judge of the strength of the piece, and whether it be sufficiently fortified or not.

This is usually done with a pair of calliper compasses.

The term is also applied to any piece of ordnance for finding whether it has its due thickness at the vent, trunnions, and neck; if the trunnions and neck are in their due order, and the chase straight, &c.

TERTII internodii pollicis extensor, in *Anatomy*. See EXTENSOR.

TERTIO *adjacente*, *Propositio de*. See PROPOSITION.

TERTIVERI, in *Geography*, a town of Naples, in Capitanata; 7 miles N.W. of Troja.

TERTIUM SAL, a *third salt*, a term used in *Chemistry* to express a salt resulting from the mixture of an acid and an alkali, which partakes so of the nature of both, as to be itself neither acid nor alkali, but neutral.

TERTRE, JOHN BAPTIST DU, in *Biography*, a missionary and writer of history, was born at Calais in 1610: and having served in the army in early life, he joined the Dominicans at Paris, and made his profession in 1635, assuming the name of John-Baptist instead of James. About five years afterwards, he was sent as a missionary to the French American islands, where he collected materials for the work which engaged his attention after his return to France in 1658: that was his "Histoire Generale des Antilles habitées par les François;" 4 vols. 4to. 1667—71. After having filled various posts in the houses of his order, he died at Paris in 1687. Moreri.

TERTUA, in *Geography*, a town of Hindoostan, in Bahar; 34 miles E. of Bahar.

TERTULLIAN, QUINTUS SEPTIMIUS FLORENS TERTULLIANUS, in *Biography*, generally reckoned the most ancient Latin father extant, was born at Carthage, not long after the middle of the second century. He was the son of a proconsular centurion, or military officer under the proconsul of Africa, and well acquainted with the Roman laws, though he does not seem to have practised the law as a profession.

He was also intimately conversant with the Greek and Roman poets, historians, orators, and philosophers, and other heathen writers of every description. His skill in Greek was so considerable, that he wrote several books in that language. It has been inferred from his parentage, and from some expressions in his works, that he was once a Heathen; but the time and circumstances of his conversion to Christianity are not known. Cave supposes that he embraced Christianity about the year 185, and was made a presbyter of the church of Carthage about the year 192. According to Du Pin, he flourished chiefly from about the year 194 to 216. Tillemont is of opinion that he was born in 160, and that he died about the year 245, when he was between 80 and 90 years of age, having lived, as St. Jerom says, to an extreme, or decrepit, old age. Cave conjectures that he died about the year 220. It is said that he was married, probably after his conversion to Christianity. Having been a member of the Catholic church for many years, he separated from it and became a Montanist, as Cave says, about the year 199, but about 205, according to Tillemont. Different accounts have been given of this change; but the most probable seems to be, that the specious pretences of the Montanists to greater mortification in fasts and continence had an influence on his temper, which was severe. But whatever might have been his reasons for adopting the principles of Montanism, they seem to have made so little alteration in him as an author, that there are several of his pieces, concerning which it is not easy to determine, whether they were written by Tertullian a Montanist, or Tertullian still a Catholic. Although, in consequence of this change, his reputation sunk in the church, yet it produced no separation between him and other Christians, except in point of discipline, which, agreeably to his temper, he wished to be harsh and rigorous. His doctrine remained the same with that of the Catholics. In process of time, however, he believed the divine inspiration of Montanus and his two prophetesses, Priscilla and Maximilla, and that they were thus enabled to make further discoveries than

had before been made, for the greater perfection of Christians. He approved of the longer, more strict, and more frequent fasts of the Montanists; he condemned all second marriages; and denied that the church was authorized to receive again into communion any who were chargeable with fornication, adultery, or any such offences, after baptism. He often arrogantly calls his own people spiritual, and the Catholics, as contemptuously, animal or carnal. We have already observed that his knowledge was extensive; his fancy also was lively; and though his temper was severe, and his mode of expression vehement and positive, yet his writings frequently manifest unaffected humility and modesty. The character given of his style by Lactantius must be universally allowed; that it is "rugged and unpolished, and very obscure;" and yet, as Cave observes, "it is lofty and masculine, and carries a kind of majestic eloquence along with it, that gives a pleasant relish to the judicious and inquisitive reader." His books still extant, though many are lost, are numerous, some of which were written before and others after he embraced the errors of Montanism. Of these, the Apology is reckoned his principal work; and has been highly commended both by ancient and modern writers; whilst his other performances are written with wit and force, and are edifying and instructive. The time when his "Apology" was written has been differently stated by various authors: some refer it to the year 200, others to 203 and 205; but Mosheim, after laborious examination, concludes that it was composed in the year 198. All allow that it was written before he joined the Montanists. Learned men generally agree, that it was not addressed to the senate of Rome, but to the governors of provinces, or perhaps to the proconsul of Africa, and the chief magistrates residing at Carthage, where it was written, according to Lardner; though others are of opinion that it was written at Rome. From this Apology, it appears that Christians underwent a variety of grievous sufferings; they were, as he says, "crucified, hung upon stakes, burnt alive, thrown to wild beasts, condemned to the mines, and banished into desert islands." That this was the case, appears also from Tertullian's book to the proconsul Scapula, not written before the year 211 or 212. The "Apology" is written for the purpose of shewing the injustice of the persecutions inflicted upon Christians, and the falsehood of the charges brought against them; and likewise to display the excellence of the Christian religion, and the folly and absurdity of that of the Heathens. His two books "Ad Nationes" are connected with his Apology, and indicate his characteristic vehemence. His address to Scapula, already mentioned, was written under the emperor Caracalla, and contains an avowal of admirable principles. "It ought," he says, "to be left to the free choice of men, to embrace that religion which seems to them most agreeable to truth. No one is injured or benefited by another man's religion; it is not an act of religion to force religion, which ought to be adopted spontaneously, not by compulsion." He proceeds to vindicate the conduct of Christians, and to shew that their religious principles induced them to pay entire obedience to the emperors, and that therefore they did not deserve to incur the penalties of treason. Another work of Tertullian has been often cited, *viz.* "De Præscriptionibus adversus Hæreticos." In this work he treats of heresy in general, and then discusses particular heresies in his five books against Marcion, in others against Praxeas, in defence of the Trinity, and against Hermogenes, and the Valentinians. In his book "On the Soul," he inquires into the nature of the soul and its properties. In his treatise "On Baptism," he absurdly maintains that the moral stain of the soul is effaced by the external washing of the body, and that punishment is likewise remitted; a doctrine

which some late divines have zealously supported. Baptism by heretics he considers as no baptism, and contends that it ought to be repeated. In cases of necessity, he thinks infant-baptism to be allowable, but he recommends deferring rather than hastening the administration of this sacrament. His book "On Penance" refutes the opinion advanced by the Montanists, that sins committed after baptism cannot be absolved by the church. In his treatise "On Idolatry," he extends this crime to practices that are almost unavoidable in society; such as bearing arms for the defence of the empire, adorning houses in honour of the prince, and using customary expressions that have any reference to Heathen mythology. In his work "De Corona Militis," he applauds a Christian soldier who refused to place a crown or garland on his head. In another work he considers "flight in time of persecution" as prohibited, and also giving money to escape it. In his treatise "De Spectaculis," he dissuades Christians from attending public shows. In his moral tracts is an exhortation to "patience," in which, as well as in a discourse addressed to martyrs or confessors, he dwells in an eloquent strain on the motives which should bind a Christian to the practice of that virtue. After his union with the Montanists, Tertullian wrote four books in opposition to the discipline of the Catholic church; *viz.* "On Modesty;" "On Monogamy;" "An Exhortation to Charity;" and "A Treatise on Faith."

Tertullian, in his various writings, has afforded plain testimonies to all the books of the New Testament, commonly received by Christians at this time, except the Epistle of James, the 2d of Peter, the 2d and 3d of John. The Epistle to the Hebrews he ascribes to Barnabas. This ancient father has been much admired: Cyprian calls him "my master." Some persons, however, have doubted whether he has done more good or harm in the Christian church. His character is judiciously appreciated by one of his biographers (*Gen. Biog.*) in the following manner. Tertullian "was certainly a man of lively parts and large acquirements, of copious invention, and warm feelings. In his reasonings, however, he displayed more fancy and subtilty than sound judgment; and the ardour of his temper inclines him to violence and exaggeration, while a propensity to superstition renders him weakly credulous and gloomily austere." His works have been frequently printed both separately and collectively. Of his whole works, the editions of Rigaltius, fol. Paris, 1641, and of Semler, Hal. Magd. 6 vols. 1770—76, are most esteemed. Dupin. Lardner. Mosheim.

TERVEERE, in *Geography*. See VEERE.

TERUEL, a town of Spain, in the kingdom of Aragon, at the conflux of the Guadalavir and the Alhambra; the see of a bishop, suffragan of Saragossa: it is defended by a citadel. This town was destroyed by the Moors, and lay a long time abandoned, but was rebuilt and repopled by Alphonso II. in the year 1171. In the year 1365, on the 25th of April, it was taken and pillaged by Peter, king of Castile; in memorial of which, the inhabitants keep the day a strict fast; 72 miles S. of Saragossa. N. lat. 40° 32'. W. long. 1°.

TERVIS, a town of Istria; 8 miles W. of Mit-terburg.

TERUM, a town of Arabia, in Yemen; 35 miles W.S.W. of Schibam.

TERUNCIOUS, in *Antiquity*, a very small brass coin in use among the Romans.

The inconvenience of such very small pieces being soon found, the teruncius became disused, but its name is still retained in reckoning, and thus it became a money of account.

The teruncius at first was a quarter of the *as*, or libra; hence,

hence, as the *as* contained twelve ounces, the *teruncius* contained three, whence the name, which is formed of the Latin *tres uncie*.

Teruncius was also used for the quarter of the *denarius*, so that when the *denarius* was at ten asses, the *teruncius* was worth two and a half; and when the *denarius* was risen to sixteen, the *teruncius* was worth four. See *DENARIUS*.

TERVOLA, in *Geography*, a town of Sweden, in the Lapmark of Kemi; 116 miles N. of Kemi.

TERWALDE, a town of Holland, in the department of Guelderland; 12 miles S. of Hattem.

TERZA, LA, a town of Naples, in the province of Otranto; 13 miles S.E. of Matera.

TERZA, Ital. the 3d in *Music*. The *terza maggiore*, or major 3d, is four semitones, or half notes, above the base; the *terza minore*, or minor 3d, is three. See *CONCORDS* and *INTERVALS*.

Tartini has added the above, and even given us a 3d found to discords.

“The same thing will happen if the same intervals are sounded by two players on the violin, distant from one another about twenty-nine or thirty feet; always using a strong bow, and holding out the notes. The auditor will hear the third found much better, if placed in the middle between them, than if nearer to one than the other. Two hautbois produce the same effect placed at a much greater distance, and even when the hearer is not in the middle, and still more if he is.”

Tartini has been unfairly treated by d’Alembert, M. Serre, and other French writers, who not only dispute his system built on the *terzo suono*, his own discovery, but give the discovery itself to another.

D’Alembert accuses him of writing in a manner so obscure, that it is impossible to form any judgment of his intentions; yet he is obliged to own that the subject itself is obscure, metaphysical, and uncertain. As to the obscurity in the phenomenon itself, we deny it; the third found, produced by two other sounds, we have always found, from innumerable experiments with two voices, two instruments, two sounds on one instrument, as double stops on a violin, violoncello, and on an organ, that the third found thus produced in the medium was the true fundamental base, such as Tartini himself has expressed by musical notes.

D’Alembert and all the French writers on the subject, have stated the case (except Rousseau) in a disingenuous manner. Even when disputing Rameau’s principles, they wish to keep him above Tartini and all foreign claimants to original discovery or improvement in music. Rousseau is envied for being the first to abuse the old French music, even by those who thought and allowed it to be bad in their other writings. See the Abbé Arnauld and M. Suard’s critique upon his *Dictionnaire de la Musique*, with those of the Abbé Rouffier, M. Laborde, &c. &c.

TERZO, in *Geography*, a town of France, in the department of the Tanaro; 2 miles S.W. of Acqui.

TERZOLA, in *Botany*, a name by which some authors have called the *cupatorium cannabinum*, or water hemp-agrimony.

TERZOWITZ, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 7 miles S.S.E. of Rakonitz.

TERZETTO, in the *Italian Music*, a little tune or air in three parts. See *TRIO*.

TERZINI, Ital. implies, in the language of practical musicians, triplets, or three notes in the time of two.

TERZO SUONO, Ital. the third found, discovered by Tartini to be produced in the medium by two sounds that can be sustained, and which third found is the true fundamental base. Upon this harmonic phenomenon Tartini has founded his system; and Mr. Stillingfleet, in his “Principles and Power of Harmony,” describes the *terzo suono* in the following manner.

“Two sounds being given on any musical instrument, which will admit of being held out for any time, and of being strengthened at pleasure, as in the trumpet, the German horn, the violin, hautbois, &c. a third found will be heard. On the violin, let the notes C E, C* E, B E, B G, Bb G, be sounded with a strong bow, the third sounds will be heard in the following manner.

TESA, in *Ancient Geography*, a town of Asia, in Carmania, upon the gulf Paragon. Ptolemy.

TESAKON, in *Geography*, a town of Africa, in the country of Nalus, on the Nuno Triftao.

TESCAPHE, in *Ancient Geography*, a town of Asia, in Mesopotamia, on the banks of the Tigris, near Seleucia. Ptol.

TESCHAR, in *Geography*, a town of Hindoostan, in Lahore; 42 miles E.S.E. of Bullauspour.

TESCHEN, a principality of Silesia, bounded on the N. by the principality of Ratibor, on the E. by Poland, on the S. by Hungary, and on the W. by Moravia. It is for the most part hilly, the Moravian chain terminating near Jablunkau, in the southern part, where also begin the Carpathian mountains. On the other hand, the north part is very swampy, and overrun with lakes and meres; notwithstanding which, there are several fertile spots. Besides which, it abounds likewise in wood. In the whole principality are five towns, part of the inhabitants of which speak German, and the others Polish. The mountains are inhabited by Walachians, who make good heyducks, or foot-soldiers. The excellent fire-arms here, called *Teschins*, receive their name from this country, and more particularly from its capital, where they are made in great quantities.

TESCHEN, or *Teiffin*, a town of Silesia, which gives name to a principality, situated on the Elfa, partly in a valley, and partly on a hill, and surrounded by a morass. It contains a Roman Catholic and a Lutheran church, a college, and four convents. The inhabitants carry on some commerce in leather, wool, and wine: here is a manufacture of fire-arms, and a particular kind of fusil, called, from the town, *Teschins*; 26 miles S.E. of Ratibor. N. lat. 49° 43'. E. long. 18° 41'.

TESCHENAU, or *TESCHINA*, a town of Bohemia, in the circle of Bechin; 8 miles E. of Sobieslaw.

TESCHONOVITZ, a town of Prussia, in Oberland; 18 miles E.S.E. of Ortelberg.

TESCUCCO. See *TEZCUCCO*.

TESCYLETIUM, in *Ancient Geography*, a town of Italy, on the coast of Magna Græcia, between the temple of

of the Lacinian Juno and the town of Locri, according to Diodorus Siculus.

TESE, in *Geography*. See TEST.

TESEGDELT, a town of Morocco, situated on a sharp rock, supposed to be impregnable; 80 miles W.N.W. of Morocco.

TESENI, a town of Asiatic Turkey, in Natolia; 34 miles S.E. of Degnizlu.

TESEREN, a town of Africa, in the country of Tafilet; 50 miles N.N.W. of Tafilet.

TESHOO-LOOMBOO, or LUBRONG, the residence of the Teshoo Lama, and the capital of that part of Thibet immediately subject to his authority, is situated in N. lat. $29^{\circ} 4' 20''$. E. long. $89^{\circ} 7'$. It is a large monastery, consisting of three or four hundred houses, the habitations of the Gylongs, or priests, besides temples, mausoleums, and the palace of the sovereign pontiff; in which is comprised also the residence of the regent, and of all the subordinate officers, both ecclesiastical and civil, belonging to the court. It is included within the hollow form of a high rock, and has a southern aspect. Its buildings are all of stone, none less than two stories high, flat-roofed, and crowned with a parapet rising considerably above the roof, composed of heath and brush-wood, inserted between frames of timber, which form a ledge below, and are fashioned above into a cornice, capped with masonry. The building is stained of a deep garnet-colour; a custom universally adopted in these regions, for distinguishing places of religious establishment, and which, when contrasted with the white walls, produces, in the appearance of their town, a very pleasing effect. All the houses have windows, the centre, or principal one, projecting beyond the walls, and forming a balcony: they are closed with black mohair curtains instead of shutters. The principal apartment in the upper story has an opening over it, covered with a moveable shed, which serves the purpose of sometimes admitting light and air, and in the winter season, occasionally, the grateful warmth of the sun. The tops of the walls are adorned with cylindrical monuments; some of which are plain, covered with black cloth, crossed by a white fillet; while others are made of copper, burnished with gold: as the palace and mausoleums are thus adorned with profusion, the view of the monastery, on approaching it from the plain, is brilliant and splendid. The plain of Teshoo-Loomboo, which is perfectly level, is encompassed by rocky hills: its length is about fifteen miles, and its southern extremity, from E. to W., is five or six miles broad. The rock, upon the southern face of which the monastery is situated, nearly occupies the whole width of the valley, and approaches so near to the hills, as to form a narrow defile, leaving room only for a road, and the bed of the river Painom-tchieu, which runs through it, and at a small distance joins the Burhampooter. A fortress commands the pass. The rock of Teshoo-Loomboo is the loftiest of all that are in its vicinity; and the monastery near its base is thus guarded from the violence of the N.W. winds. From the summit of this rock the eye commands a very extensive prospect, and the most interesting object in view is the celebrated river Burhampooter, called in the language of Thibet Erechoomboo. Here it receives the tributary waters of the Painom-tchieu. Turner's Tibet.

TESI TRAMONTINI, VITTORIA, in *Biography*, one of the most renowned female singers that Italy has produced. She was born at Florence in 1690; began her vocal studies under the maestro di cappella Francesco Redi; then went to Bologna, and became a pupil of Campeggi; and received her last polish from Bernacchi. But she was no less admired

for the dignity, grace, and propriety of her action, than her vocal powers.

Quantz, who heard her at Dresden in 1719, in the famous opera that was performed on occasion of the nuptials of the prince royal of Poland, sing with Senesino, the Berfelli, wife of Lotti, Durestante, and the Faustina, characterizes her in the following masterly manner.

"Vittoria Tefi had by nature a masculine, strong, contralto voice. In 1719 she generally sung, at Dresden *all' ottava*, such airs as are made for base voices; but afterwards, besides the majestic and serious style, she had occasionally something coquettish in her manner, which was very pleasing. The compass of her voice was so extraordinary, that neither to sing high nor low gave her trouble. She was not remarkable for her performance of rapid and difficult passages; but she seemed born to captivate every spectator by her action, principally in male parts, which she performed in a most natural and intelligent manner." Life of Quantz, written by himself.

She sung at Naples in 1725, and at Vienna in 1748, where she remained till the time of her decease, in 1775, at 85 years of age.

She was the mistress of the Teuberinn and the De Amicis, both as justly famed for their acting as singing.

We were told at Vienna in 1772, that she had long quitted the stage, though the remembrance of her talents was so deeply impressed in the minds of many excellent judges, that whenever she was mentioned, it was to the disadvantage of all subsequent female singers. She had been very sprightly in her day, and yet was in high favour with the empress-queen in her latter years. Her story is somewhat singular. She was connected with a certain count, a man of great quality and distinction, whose fondness increased by possession to such a degree as to determine him to marry her: a much more uncommon resolution in a person of high birth on the continent, than in England. She tried to dissuade him: enumerated all the bad consequences of such an alliance; but he would listen to no reasoning, nor take any denial. Finding all remonstrances vain, she left him one morning, went into a neighbouring street, and addressing herself to a poor labouring man, a journeyman baker, said she would give him fifty ducats if he would marry her; not with a view to their cohabiting together, but to serve a present purpose. The poor man readily consented to become her nominal husband: accordingly they were formally married; and when the count renewed his solicitations, she told him it was now utterly impossible to grant his request, for she was already the wife of another; a sacrifice she had made to his fame and family.

Since that time she had lived many years with a man of great rank at Vienna, of nearly her own age; probably in a very chaste and innocent manner.

TESIA, in *Geography*, a town of New Mexico, in the province of Mayo; 45 miles E.S.E. of Santa Cruz.

TESIN, a town of Syria, celebrated for its olive oil; 18 miles N.E. of Antioch.

TESINO, a department of Italy, formed of the Pavese. It contains 156,471 inhabitants, who elect twelve deputies. Pavia is the capital.—Also, a river of Italy, which rises in mount St. Gothard, and passing through lake Maggiora, empties itself into the Po, at Pavia.

TESINO, or *Tessin*, a town of the county of Tyrol; 24 miles N.E. of Trent.

TESKELA, a town of Finland; 70 miles E. of Biorneborg.

TESKOWA, a town of Poland, in Volhynia; 40 miles E. of Lucko.

TESORO, a small island in the Spanish Main, near the coast of South America. N. lat. $10^{\circ} 8'$. W. long. $75^{\circ} 46'$.

TESPIS, in *Ancient Geography*, a town of Asia, in the interior of Carmania, and near Carmana. Ptolemy.

TESS, in *Geography*, a river of Moravia, which runs into the March, 8 miles N. of Muglitz.

TESSAILAH, a town of Algiers; 20 miles S. of Oran.

TESSALON. See THESSALON.

TESSARACONTA, τεσσαρακοντα, among the Athenians, were forty men who went their circuits round the several boroughs, and had cognizance of all controversies about money, if not above ten drachms; as also of actions of assault and battery. Potter, *Archæol. Græc.*

TESSARACONTERIS, in the *Naval Architecture of the Ancients*, a word used to express a fort of galley, in which there were no less than forty tiers of rowers one above another. See ENNERIS and POLYCROTA.

TESSARA-COSTA, in our *Ancient Writers*. See QUADRAGESIMA.

TESSARACOSTON, τεσσαρακονστη, in *Antiquity*, a solemnity kept by women on the fortieth day after child-birth, when they went to the temple, and paid some grateful acknowledgments for their safe delivery. Pott, *Archæol. Græc. tom. i. p. 432. and tom. ii. p. 335.*

TESSARINI, CARLO, in *Biography*, first violin, and leader of the band in the metropolitan church at Urbino, was born at Rimini in 1690; he was a spirited performer on his instrument, and a very voluminous composer. His style was light and limsy, compared with that of Corelli and Gemiani; but his concertos not being very difficult, were much played in country concerts in our own memory, with those of Alberti, Albinoni, and Vivaldi.

Tessarini's first publication at Amsterdam has a title-page of great promise; but whether the promise was ever performed, sceptics in these incredulous days will be much inclined to doubt. The title is in French, but literally translated, is the following: "A new Method for learning theoretically, in a Month's Time, to play on the Violin, divided into three Classes, with progressive Lessons for two Violins." Then twelve violin concertos; twelve flute solos; the master and scholars; divertimenti for two violins; twelve violin solos; six divertimenti for two violins, in canon, &c. &c. He lived till the year 1672, in the perpetual labour of publication; but his productions would now be as difficult to find as those of Timotheus and Olympus.

TESSE, in *Geography*, a town of France, in the department of the Sarthe; 15 miles S.W. of Le Mans.

TESSELÆ, a word used in *Pharmacy*, to express lozenges cut into regular figures.

TESSELARII, among the Romans, artificers of chequered or mosaic work.

TESSELATED PAVEMENT, *pavimentum tessellatum*, a rich pavement of mosaic work, made of curious small square marbles, bricks, or tiles, called *tesselle*, from the form of dies.

Tesselated pavements were much used in the tents of the Roman generals.

TESSERA, in *Roman Antiquity*, denoted in its primary sense a cube or dye; so called from the Greek word τεσσαρα, or τεσσαρα, four; respect being had to its number of sides, distinct from the two horizontal planes, above and below. And it was thus distinguished from the *talus*, which, being round at each end, contained only four planes or faces on which it could stand: and therefore, when thrown, had no

more than two side faces in view. Hence *ludere talis et ludere tessera* are spoken of by Roman writers as two different games. The syllable *tes* occurs often in Roman inscriptions.

The word *tessera* was applied to many other things, not so much from a similitude in the figure, as from the relation they bore to some other thing of which they were the sign or token; as the points on the upper plane of the dye denoted the good or ill success of the cast.

The *tessera hospitalis* was either public or private. As to the former, we find among the inscriptions published by Gruter, instances of two municipal towns which put themselves under the patronage of the Roman governor; and the reciprocal engagements between them, engraved on two copper-plates in the form of an oblong square, with a pediment at the top, is called in both *tessera hospitalis*.

The design of the latter was to cultivate or maintain a lasting friendship between private persons and their families; and gave a mutual claim to the contracting parties, and their descendants, of a reception and kind treatment at each other's houses, as occasion offered. For which end those tesserae were so contrived, as best to preserve the memory of that transaction to posterity. And one method of doing this was by dividing one of them lengthwise into two equal parts, upon each of which one of the parties wrote his name, and interchanged it with the other. From this custom came the prevailing expression *tesseram hospitalem infringere*, applied to persons who violated their engagements.

The *tessera frumentaria* were small tallies given by the emperors to the populace of Rome, entitling them to the reception of a quantity of corn from the public at stated seasons. The person who had the inspection of these was called *tesserarius*. They were made of wood and of stone.

There was another kind of tessera which intitled persons to a sight of the public games and other diversions, usually made in the form of an oblong square.

The *tessera militaris* was a signal given by the general, or chief commander of an army, as a direction to the soldiers for executing any duty or service required of them.

This, upon urgent occasions, was only vocal; but, in ordinary cases, it was written on a tablet, commonly made of wood. Beside the civil and military tesserae; there are others which related to religious affairs, and may be called sacred. Phil. Transf. vol. xlv. art. 12.

TESSERMUIT, in *Geography*, an island near the S.W. coast of East Greenland. N. lat. $59^{\circ} 59'$. W. long. $44^{\circ} 20'$.

TESSET, a town and district of Africa, in the country of Sahara; 170 miles S. of Morocco. N. lat. $15^{\circ} 24'$. W. long. 7° .

TESSIN, CHARLES GUSTAVUS, in *Biography*, a Swedish count and considerable statesman, was born at Stockholm in 1695, and received the rudiments of his education under his father. In 1714 he set out on his travels, and continued them through various countries of Europe for five years, availing himself of every opportunity that occurred of acquainting himself with their respective constitution and laws. At the age of twenty-five he was deputed to the courts of Great Britain, Denmark, and France, and also to the States of Holland, to announce the accession of Frederic I. to the Swedish throne; and in 1725 he was sent to Vienna, to solicit the attention of that court to the new treaty of alliance between Sweden and Russia. On the death of his father, in 1728, he succeeded him as principal intendant of the court, and in order to qualify himself for the office, he undertook a new tour at his own expence. In 1735 he was again dispatched

to the court of Vienna, where he remained two years. He was chosen by the nobility speaker at the famous diet of 1738, on which occasion he obtained, in recompence of his conduct, a gold medal, bearing on one side his crest, and on the other the motto "Conscius Recti." He was appointed in 1739 to conduct an embassy from this diet to France, and resided at Paris till the year 1742, concluding during this interval an advantageous treaty of commerce with the king of the Two Sicilies, and terminating a subsidiary treaty of alliance with France, by which Sweden was to receive in the course of three years 27 tons of gold. In 1743 he was sent to Denmark, and in the following year to Berlin, on business of great importance. At Berlin he was honoured with the Prussian order of the Black Eagle. He occupied several other stations of dignity and trust, the duties of which he discharged with singular wisdom and fidelity. But the most important office assigned him, was that of preceptor to the crown prince, Gustavus III., to which he was appointed in 1747. On this occasion he wrote his "Letters addressed to a Young Prince," for the use of his royal pupil, which were afterwards translated into most of the languages of Europe. Retiring from public business in 1761, he lived on his estate till the time of his death, which happened in January 1770. Count Tessin was a zealous patriot and enlightened citizen, and a distinguished patron of letters. With a view of encouraging the arts and sciences, he made a great collection of books, pictures, drawings, coins, and other curiosities. But notwithstanding his various excellent qualities, his enemies were assiduous in fruitless attempts to throw a shade over his character, as may be seen in a work entitled, "An Historical Account of the State of Sweden under Frederic I." Gen. Biog.

TESSIN, in *Geography*, a town of the duchy of Mecklenburg; 18 miles S.E. of Rostock.

TESSIURSAK, an island near the W. coast of West Greenland. N. lat. 61° 10'. W. long. 47° 30'.

TESSOUA, a considerable town of Africa, in the country of Fezzan; 100 miles E.S.E. of Mourzouk. Near this town, a river, now overwhelmed by the moving sands, but formerly a deep and rapid stream, had its course.

TESSOUELLE, a town of France, in the department of the Mayne and Loire; 5 miles S. of Chollet.

TESSUA, a town of Hindoostan, in Rohilcund; 18 miles S.S.E. of Bercilly.

TESSUE, a town of Persia, in the province of Adirbeitzan; 50 miles W. of Tauris.

TESSUNTEE, a town of the state of Georgia; 80 miles W. of Tugeloo.

TESSUT. See TEECUT.

TESSY, a town of France, in the department of the Channel; 9 miles S. of St. Lo.

TEST, in *Metallurgy*, is a vessel of the nature of a coppel, used for large quantities of metals at once, and formed of the same materials.

The coppels, or small vessels, serve for operations of this kind, when small quantities only are concerned; but when larger are worked on, vessels of a larger size and coarser texture are employed, which are distinguished by the name of *tests*.

These are usually a foot and half broad, and are made of wood-ashes, not prepared with so much care as for coppel-making, and mixed with finely powdered brick-dust; these are made into the proper shape, either by means of a shallow vessel, made of crucible earth, or cast-iron, of proper dimensions, or only an iron ring, or hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or

more, according to the quantity of metal to be tested at once.

To make them in the first manner, an earthen vessel is to be procured, not glazed within, and by its depth and breadth proportioned to the quantity of metal to be worked; the inside of this vessel is to be well moistened with fair water, that the ashes to be put into it may adhere the better. Put into this vessel, thus prepared, the ashes and brick-dust before-mentioned, and first moistened either with water alone, or with water with a little white of an egg mixed in it; let the quantity of this be so much as will half fill the vessel, then press the mass with a wooden indented pestle, or, if not for a very large test, with a wooden cylinder, only of an inch thick: when thus pressed down add fresh ashes, and press them a second time, as in the making of coppels, and repeat this addition of fresh ashes till the earthen vessel be nearly full; then remove the superfluous ashes with an iron ruler, and let the inequalities remaining at the border be smoothed with a wooden or glass ball rolled round about. This done, you are to cut the cavity with a bowed iron, that you may have a broad spherical segment, not very deep; and lastly, by means of a sieve, strew this cavity carefully and regularly over with dry ashes of bones of animals, ground extremely fine, and squeeze these hard in, by the rotation of the wooden or glass ball. Thus you have a test finished, which, together with its earthen pot, must be set in a dry warm place.

To make the tests in the other manner, or by means of an iron ring; let a ring of that metal be filled with ashes mixed with brick-dust, and moistened as before mentioned, in such manner that they may rise considerably above the ring; then press them strongly either with your hands, or with an indented pestle, and afterwards, with gentle blows of a rammer, press the ashes from the circumference toward the centre, in a spiral line, and that in such manner, that, after having been sufficiently pressed, they may be a small matter higher than the brink of the ring. If there are now any vacancies in the mass, empty the ring, and fill it again with more ashes; for if you should attempt to fill up these by adding, were it but ever so little, ashes, the second, or additional quantities, will never cohere so firmly with the first, but that they may probably separate in the operation.

This done, turn the ring upside down, and on the other side, or bottom, take out the ashes to the quantity of one-third part of the depth of the ring, and again fill the cavity with the same ashes, in such a manner that there may remain no sensible cavity,

When the mass is thus prepared, cut out a cavity in the larger surface of the ring, with a bowed iron, as in the former method.

The Germans have, beside these, another kind of tests, which they call *treibscherben*. These are a sort of vessels which resist the most violent fire, and are so extremely compact, that they sometimes will retain not only melted metals, but even the glass of lead itself.

The figure and size of these vessels may be the same with that of the coppel, but they are usually made larger; and the great difference of these tests from coppels, and from the ordinary tests, which are indeed only a kind of large and coarse coppels, is, that the matter of these is more compact and coherent.

The matter for making these tests is thus prepared: take of the purest and finest clay a sufficient quantity, make it into balls, and dry them either in the air, or on the fire; when dried, beat them to powder in a mortar, and pour on the powder a great quantity of warm water; let this mixture rest a while, and when the clay has subsided, pour off the

the water which swims at top; and let this washing be so often repeated, that all the most minute lumps of the clay be broken, and whatever salt it contains perfectly washed out: then add to this fine clay, of the purest sand, of powder of calcined flints, ground, and well washed, of faulty but clean Hessian crucibles, or of any incombustible stones ground very fine, such a quantity as will render the mass thick, and hardly adhering to the hands in kneading it, or pliant when rolled into a thin lamina.

This is the matter for making this sort of tests; but, before any quantity of the vessels be made of this earth, it will be prudent first to finish a single one, and try it, by putting on it a quantity of glass of lead, and exposing it for an hour or more to the strongest fire; by this trial you will be certain whether or not the mass is capable of making vessels that will resist both the fire and the glass of lead; and by no other means but this trial is it possible to determine the due proportion of the mixture of the ingredients for this use, on account of the variety of the clays. Nature in some places affords a clay so well tempered, that it is extremely proper for the making of tests without any preparation, or without the admixture of any other matter. Sometimes this only requires a simple washing, but commonly it is necessary to make it into balls, and powder or wash them as before directed.

On the trial of a test made of this, or the former mixed clay, if it runs into glass, you must add to it of the powder of stones, especially such as best resists the fire. Great care is to be taken not to add too much powdered chalk to these compositions, since if the matter is tempered with that alone, the tests will indeed resist the fire very well, but being too porous, they will yield a passage to litharge, which will soften them to such a degree, that they will either fall asunder of themselves, or be totally crushed when taken hold of with the tongs.

These vessels are to be made in the following manner: rub over the sides and bottom of a small mortar, and also its pestle, with oil, or with the fat of bacon; fill it two-thirds full of prepared clay, then make a slight impression with your fingers in the middle of the clay; then place the bottom of the pestle there, and force it down with blows of a hammer, the stronger the better. When thus properly hollowed, take it out of the mortar, and pare its edges, and dry it, as the coppels are dried, in the air, in a dry warm place.

Tests thus prepared may be used as soon as dry, unless for salts or litharge; but these bodies, when melted in vessels not first baked or hardened in the fire, always make their way through them.

Some of the German writers also recommend, both for tests and coppels, a sort of friable opaque stone, called white spath, which appears to be a species of gypsum, or of the stones from which plaster of Paris is prepared. The spath is directed to be calcined with a gentle fire, in a covered vessel, till the slight crackling, which happens at first, has ceased, and the stone has fallen in part into powder; the whole is then reduced into subtle powder, which is passed through a fine sieve, and moistened with so much of a weak solution of green vitriol, as is sufficient for making it hold together. Gellert, however, finds, that if the stone is of the proper kind, which can be known only by trials, calcination is not necessary. These tests are liable to soften or fall asunder in the fire, which inconvenience may be remedied, according to Scheffer, by mixing with the uncalcined stones somewhat less than equal its weight, as eight-ninths of such as had been already used and penetrated by the scoria of the lead, taking that part of the old test which

appears of a green-grey colour, and rejecting the red crust on the top. But from his account it appears, that these tests are less durable than those made of the ashes of bones, though much superior to those of wood-ashes. Vegetable ashes, which stand pretty well the testing of silver, can scarcely bear any great quantity of gold, which requires a considerably stronger fire than the other; but bone-ashes, says Dr. Lewis, answer so effectually, and are among us so easily procured, that it is unnecessary for the refiner to search for any other materials. Cramer's Art of Assaying, p. 60. 62. Lewis's Com. Ph. Tech. p. 144.

TEST-Liquor, a term used by our dealers in brandies, &c. for a liquor which they use as a test of brandy, &c. to prove whether they be genuine, or mixed with home spirit. The people who use this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend that this liquor will shew, by the colour which it makes on its being poured into brandy, whether it be genuine or adulterated; or if not genuine, in what proportion the adulterating spirit is mixed with it.

The whole fact is this: if a little common green or white vitriol be dissolved in some fair water, it makes a test-liquor, a few drops of which being let fall into a glass of old French brandy, will turn the whole to a purple or fine violet-colour; and by the strength or paleness of this colour, the dealers judge the brandy to be genuine or mixed in different proportions, with home spirits.

Old French brandy, having long lain in the cask, takes a dilute tincture of the wood of the cask, that is, of oak; and this being of the same nature with a solution or tincture of galls, naturally turns blueish or blackish with vitriol. A new distilled brandy, though wholly foreign, would not give this test; and a common malt spirit, with oak chips infused in it, will turn as dark as the finest brandy. While our distillers, indeed, had nothing in use for the colouring of their spirits but burnt sugar, it was possible to make some guess at an adulteration with them, because the brandy, in this case, would not become blackish in proportion to its former colour; the sugar colour not turning to ink with the vitriol, like the other: but our distillers have since found a way of using an extract of oak for the colouring of their spirits, and since that, this test-liquor is of very little use, our common spirits, of any kind, turning as deep with it as the foreign brandies.

The very best way of making this test-liquor, is with a calcined vitriol of iron, dissolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the finest blue to any spirituous tincture of oak.

The English were, at one time, very fond of high-coloured brandies, and it was then that the use of this test-liquor was most esteemed; afterwards we, as well as other nations, finding that this colour was only owing to the cask, began to dislike, and to favour the pale brandies: at length we fell into the use of such as were wholly limpid and colourless, and the re-distilling of all the old brandies of which people were possessed, took place; on this the test-liquor was found to be of no use at all, and accordingly rejected; but as we are of late again come into the esteem of coloured brandies, and that with great justice, as the colour, when genuine, is a certain mark of the age of the liquor, this test-liquor is again got into more credit than it deserves.

The famous Helvetian styptic depended wholly on this accident for its colour; and it was no small mortification to our chemists, when, some years ago, it was introduced into use among us, that they could not make it with our own spirits, but must be at the expence of true French brandy

TEST-ACT.

brandy for it; our own spirits, though equally coloured, would never make that violet tincture, because their colour was owing to burnt sugar, not a tincture of oak. At length this mystery was explained, and a little scrapings of galls made all those quantities of this styptic, which had been set by as good for nothing, perfectly fine and well-coloured. Shaw's Essay on Distillery.

TEST-ACT, in Law, is the statute 25 Car. II. cap. 2. (1673) which directs all officers, civil and military, to take the oaths, and make the declaration against transubstantiation, in the court of king's bench or chancery, the next term, or at the next quarter sessions, or (by subsequent statutes) within six months after their admission; and also within the same time to receive the sacrament of the Lord's supper, according to the usage of the church of England, in some public church, immediately after divine service or sermon, and to deliver into court a certificate thereof, signed by the minister and churchwarden, and also to prove the same by two credible witnesses, upon forfeiture of 500*l.* and disability to hold the same office. Besides this penalty, if, without taking the sacramental qualification within the time prescribed by the act, a person continues to occupy a civil office, or to hold a military commission, and is lawfully convicted, then he is disabled from thenceforth, for ever, from bringing any action in course of law, from prosecuting any suit in any court of equity, from being guardian of any child, or executor or administrator of any person, as well as from receiving any legacy. For an account of the nature and operation of the CORPORATION ACT, we refer to that article.

The word *test* signifies *proof* or *trial*, being formed of *testis*, *witness*; this act being established with a view to exclude Roman Catholics from any share in the government, though it has operated to the exclusion of Protestant dissenters in general. The Corporation act, enacted in the year 1661, the 13th of Charles II., was principally, but not wholly, designed against Protestant Non-conformists. It was passed in a period of great heat and violence, the year after the Restoration; and it paved the way for the act of uniformity, which soon after passed. The king, with his ministers, and the majority in both houses, hated the Presbyterians, whom they considered, whether justly or not, as the authors of the late rebellion. Great power still remained in their hands, for, during the Protectorate, they had been appointed magistrates in all the country towns. To leave authority in such hands seemed dangerous: it was therefore judged expedient to regulate the corporations, and to expel those magistrates, whose principles were inimical to the constitution, civil and ecclesiastical. This gave rise to the Corporation act. The sacramental clause, however, in the Corporation act was intended against the Catholics; for, as the other provisions of the statute, by dispossessing the enemies of the court, had established the influence of the crown in all the corporations of the kingdom, the parliament was apprehensive that in the next reign, under a Catholic king, all corporation offices would be filled with Catholics. Besides, before the passing of the act of uniformity, those that were afterwards called dissenters, were within the inclosure of the church, and consequently participated in her sacraments, so that the sacramental clause must therefore have been intended as a guard against the Catholics, to whom it effectually applied, and not as a guard against those who were afterwards called dissenters, on whom, at that period, it could not operate.

It must also be allowed, that the original design of the test was not so much to exclude the Protestant dissenters, as the papists, as the Catholics were then called. It was brought in by the patriots, in the reign of Charles II.,

under their apprehension of popery, and a popish successor; and when, during the debate in the house of commons, it was observed, that it was drawn in such a manner as to comprehend the Protestant dissenters, the court greatly endeavoured to avail themselves of that circumstance in order to defeat the bill. But the dissenting members disappointed them, by declaring, that they had rather confide in the justice and generosity of parliament, to pass some future bill in their favour, than be the occasion of retarding or defeating the security, which the present bill was calculated to afford to the liberties of their country. Their patriotism produced, soon afterwards, a bill for their relief from the penal laws; but the parliament was prorogued, through the resentment of the court, to prevent its passing; and when, notwithstanding this, a bill in favour of the dissenters did afterwards pass both houses, *viz.* in the year 1680, and lay ready for the royal assent, the court ventured upon a very extraordinary expedient: the clerk of the crown was ordered to convey away the bill, and, accordingly, it was never afterwards to be found. The particular test of receiving the sacrament according to the rites of the church of England, was calculated to exclude the papists rather than the Protestant dissenters; as it was no uncommon thing for the latter, at that time, to receive the sacrament occasionally in the church of England, in order to express their charity towards it, as a part of the church of Christ. If it had been the design of the legislature to exclude all from civil offices but those who have a real affection for the constitution and worship of the church, it is apprehended they would have appointed the test to be, not merely once taking the sacrament at church, but a stated and constant conformity to its religious services.

It has been alleged, however, that though the Test act was designed against the Catholics, yet that few, even then, of the number, merited a treatment so severe. They, it is said by their advocates, had no concern in the views of Charles or his brother, in the schemes of wild ministers, or in the machinations of bad politicians. They had suffered much in the royal cause, and were pining in penury and distress, under the additional pressure of cruel laws. But whatever might be the reasons, real or pretended, for passing an act, of which Catholics were the principal ostensible objects, the case is now very much altered, and Catholics have assumed a new character, which entitles them, in the judgment of many, not merely to protection, but to a participation of the privileges of their fellow-subjects.

As the question concerning the repeal of the disqualifying laws which we have already mentioned, has been, and is likely soon again to become a subject of public discussion, and as it is a subject, generally considered, of great importance and interest, it may not be thought improper to state the arguments for and against the repeal of those excluding statutes, comprehending both Protestant dissenters and Catholics, in as concise a manner as possible. The general principles upon which the equitable decision of this question depends, are such as follow:—Every man has an undoubted right to judge for himself in matters of religion; nor should any mark of infamy, or any civil penalty, be attached to the exercise of this right:—Every man has a right to the common privileges of the society in which he lives; and among these common privileges, a capacity: law for serving his sovereign and country is one of the most valuable, distinguishing a *legal capacity* of service, from a *right* to an actual appointment, which depends upon the choice of his sovereign, or of his fellow citizens; and this capacity of serving the state is a right of such high estimation, and of such transcendent value, that exclusion from it

TEST-ACT.

is deemed a proper punishment for some of the greatest crimes:—Actions, and not opinions, political or religious, are the proper objects of human authority and cognizance:—No man, who does not forfeit that *capacity* of serving his sovereign and country, which is his natural right, as well as the honour and emoluments that may happen to be connected with it, by overt-acts, ought to be deprived of them; and disabilities that are not thus incurred are unjust penalties, implying both disgrace and privation:—Punishment, without the previous proof of guilt, cannot be denied to be an injury; and injuries inflicted on account of religion are undoubtedly persecutions:—The ends of civil society can never justify any abridgment of natural rights that is not essential to these ends:—The institutions of religion, and the ordinances of civil government, are distinct in their origin and their objects, in the sanctions that enforce them, and the mode in which they are administered:—The institution of the Lord's supper, being wholly of a religious nature, and appointed merely as a memorial of his death, is improperly applied to the secular ends of civil society; and if it be so applied, it is not only an improper, but in many cases an insufficient, test of the principles and character of those to whom it is administered. Such are some of the leading principles, which have been the subjects of discussion in the debates that have occurred, both among writers and among our legislators, in considering the expediency of repealing the test laws. The case of the Catholics and of the Protestant dissenters has been repeatedly argued in both houses of parliament, and may probably again become the subject of public discussion. Many (indeed most) of the same arguments apply to both descriptions of persons; but we shall chiefly restrict ourselves to the pleas of the dissenters. They have urged, that being well-affected to his majesty and the established government, and ready to take the oaths required by law, and to give the fullest proof of their loyalty, they think their scruple to receive the sacrament after the manner of the church of England, or after the manner of any church, as a qualification for an office, ought not to render them incapable of holding public employments, civil or military: they also allege, that the occasional receiving of the Lord's supper as a qualification for a place, cannot, in the nature of things, imply that those who thus receive it, mean to declare their full and entire approbation of the whole constitution and frame of the established church; some men may be compelled by their necessities, or under the allurements of secular advantages, to do what they would not do, if they were left to their free choice. Others, perhaps, may comply with the sacramental test who are not even Christians, and who therefore cannot be supposed to wish well to Christianity itself, or to any national establishment of it whatsoever. Hence they are led to think, that such a test can be no real or effectual security to the church of England. Conceiving that they have a right, as *men*, to think for themselves in matters of religion, and that this right is prescribed and sanctioned by the Author of Christianity; and that they have a right, as *citizens*, to a common chance with their fellow-subjects for offices of civil and military trust, if their sovereign or fellow-citizens should think them worthy of confidence; they cannot be of opinion that any of the ends or objects of civil society require that these rights should be superseded, and that they should be excluded from the service of the state. Their advocates plead on their behalf, that the continuance of those acts which invade their rights is so far from being necessary to the well-being of the state, or to the establishment of the national church, that they are actually pernicious both to the state and church, and ought to be repealed. Their in-

utility is shewn by referring to the higher trust of legislative authority, to which the dissenters are admitted without hesitation or reserve, and without submitting to any such test. An exciseman surely, it is said, does not sustain a more important office, neither is it necessary that he should make a profession of his Christian faith more than a member of the house of commons or the house of peers. The principles of the dissenters, their attachment to the constitution, and their zeal in support of it, have been sufficiently manifested in a variety of instances, from the Revolution to the present day; and yet can it be asserted, that their exclusion from the service of the public is necessary or beneficial to the state? Can it be said that the continuance of the disabilities to which their profession subjects them, is necessary for the safety or honour of the church? The establishment of a church requires a legal provision for its ministers; but it does not require for its laity an exclusive right to civil and military trusts. The establishment of the church of England consists in her tithes, her prebendaries, her canonries, her archdeaconries, her deaneries, and her bishoprics. These constituted her establishment before the Corporation and Test acts had any existence: and they will equally constitute her establishment if these acts should be repealed. In Scotland they have had no such acts; and yet Scotland has an established church. In Ireland these acts have been repealed; and yet the established church of Ireland remains. In Holland, Russia, Prussia, Germany, &c. they have no such acts. As to the intimate and beneficial connection between church and state, on which some have grounded the supposed propriety and necessity of these laws, it would be sufficient to refer to the authority of archdeacon Paley, who has stated what ought to be the single end of church establishments. (See RELIGION.) Upon an appeal to history, it has been argued that the civil government maintained itself in former times, when *unconnected* with the church; and the disturbances which terminated in the ruin of both church and state, are said to have originated in the intolerant spirit and arbitrary proceedings of some ecclesiastics, who had themselves exercised powers, and had instigated their unhappy sovereign to actions and claims at least as contrary to, and subversive of, the true spirit of the constitution, as any of those violences of the times immediately succeeding, which have been so justly reprobated. In this connection, we may refer to the speech of an able advocate for the repeal of the disabling statutes: who maintains that no human government has a right to inquire into men's private opinions, to presume that it knows them, or to act on that presumption. Men should be tried by their actions, not by their opinions. This, if true with respect to *political*, was more peculiarly so with regard to *religious* opinions. In the position, said Mr. Fox, that the actions of men, and not their opinions, were the proper objects of legislation, he was supported by the general tenor of the laws of the land. History, however, afforded one glaring exception in the case of the Roman Catholics. The Roman Catholics, or rather the Papists, as they were then properly denominated, had been supposed by our ancestors to entertain opinions that might lead to mischief in the state. But it was not their religious opinions that were feared. Their acknowledging a foreign authority paramount to that of the legislature; their acknowledging a title to the crown superior to that conferred by the voice of the people; their political opinions, which they were supposed to attach to their religious creed, were dreaded, and justly dreaded, as inimical to the constitution. Laws therefore were enacted to guard against the pernicious tendency of their political, not of their religious, opinions; and the principle thus adopted, if not founded on justice,

TEST-ACT.

was at least followed up with consistency. Their influence in the state was feared, and they were not only restricted from holding offices of power or trust, but rendered incapable of purchasing lands, or acquiring influence of any kind. But if the Roman Catholics of those times were Papists in the strictest sense of the word, and not the Roman Catholics of the present day, still he would say, that the legislature ought not to have acted against them, till they put in practice some of the dangerous doctrines which they were thought to entertain. Disability and punishment ought to have followed, not to have anticipated, offence. Those who attempted to justify the disabilities imposed on the dissenters, must contend, if they argued fairly on their own ground, not that their religious opinions were inimical to the established church, but that their political opinions were inimical to the constitution. If they failed to prove this, to deprive the dissenters of any civil or political advantage, was a manifest injustice; for it was not sufficient to say to any set of men, we apprehend certain dangers from your opinions, we have wisely provided a remedy against them, and you, who feel yourselves aggrieved, calumniated, and proscribed, by this remedy, must prove that our apprehensions are ill-founded. The *onus probandi* lay on the other side; for whoever demanded that any other person should be laid under a restriction, it was incumbent on him first to prove that the restriction was necessary to his safety, by some overt act, and that the danger he apprehended was not imaginary but real. Was it seriously to be contended, that religion depends upon political opinions; that it can subsist only under this or that form of government? It was an irreverend and impious opinion to maintain, that the church must depend for support, on its being an engine, or ally, of the state, and not on the evidence of its doctrines, to be found by searching the scriptures, and the moral effects it produced on the minds of those whom it was its duty to instruct. See TOLERATION.

Mr. Pitt agreed with Mr. Fox in admitting, as a general principle, that the religious opinions of any set of men were not to be restrained or limited, unless they should be found likely to prove the source of inconvenience to the state: nor ought the civil magistrate, in any other point of view, to interfere with them; but he maintained, that when religious opinions are such as *may* produce a civil inconvenience, the government has a right to guard against the probability of the civil inconvenience being produced; nor ought they to wait till, by being carried into action, the inconvenience has actually arisen. It was not therefore on the ground that the dissenters *would* do any thing to affect the civil government of the country, that they had been excluded from civil offices, but that if they had any additional degree of power in their hands, they *might*. On the other hand it has been pleaded, that to restrain men's civil rights from the supposed *tendency* of their opinions, is a very dangerous principle, as it must render their condition precarious and wholly dependent on the prejudices and will of the magistrate, and warranted unlimited restraint, and almost every species of persecution.

Mr. Pitt, premising that the establishment of a settled form of church and of its ministers is necessary to the civil government of the country, suggests the impropriety of distributing the emoluments and offices of the established church among persons who, however respectable their characters might be, were not members of the same communion; but others say, that the emoluments and offices of the established church are not the objects contended for, but those of the state, unless the church and state be absolutely identified. He also says, that these offices may be considered as matter of favour, because it is consistent with the government of this country, that all offices should be given at

its discretion; and here, he says, from the delicate nature of the case, the legislature had thought proper to interpose, and to restrain the supreme magistrate, the head of the executive authority, and limit him in his appointment to these offices; but surely, as he contends, this differed essentially from any degradation, disgrace, or punishment of the dissenters. Others, however, have considered this kind of reasoning as fallacious, both in its principle, and in the inference deduced from it.

Mr. Fox concurred with lord North, who, though an advocate for the continuance of these disqualifying laws, bore testimony to the principles and character of the dissenters, in his avowal of their steady attachment to government; and he added, that their religious opinions were favourable to civil liberty, and that the true principles of the constitution had been remembered and affirmed by them, at times when they were forgotten, perhaps betrayed, by the church. See DISSENTERS.

Mr. Fox maintained, that the Test act was altogether inadequate to the end it had in view. The purport of it was, to protect the established church, by excluding from office every man who did not profess himself well affected to that church. But a professed enemy to the hierarchy might go to the communion table, and afterwards say, that in complying with a form, enjoined by law, he had not changed his opinion, nor, as he conceived, incurred any religious obligation whatever. There were many men, not of the established church, to whose services their country had a claim. Ought any such man to be examined, before he came into office, touching his private opinions? Was it not sufficient that he did his duty as a good citizen? Might he not say, without incurring any disability, "I am not a friend to the church of England, but I am a friend to the constitution, and on religious subjects must be permitted to think and act as I please." Ought their country to be deprived of the benefit she might derive from the talents of such men, and his majesty prevented from dispensing the favours of the crown, except to one description of his subjects? But whom did the test exclude, the irreligious man, the man of profligate principles, or the man of no principle at all? Quite the contrary; to such men the road to power was open; the test excluded *only* the man of tender conscience; the man who thought religion too distinct from all temporal affairs, that he held it improper to profess any religious opinion whatever, for the sake of a civil office. Was a tender conscience inconsistent with the character of an honest man? or did a high sense of religion shew that he was unfit to be trusted? Allowing that the established church ought to be protected, it was natural to inquire what was the established church? Was the church of England the established church of Great Britain? Certainly not: it was only the established church of a part of it; for, in Scotland, the kirk was as much established by law as the church was in England. The religion of the kirk was wisely secured, as the established religion of Scotland, by the articles of Union; and it was surely absurd to say, that a member of the kirk of Scotland, accepting an office under government, not for the service of England exclusively, but for the service of the united kingdom, should be obliged to conform, not to the religious establishment of Scotland, in which he had been bred, but to the religious establishment of England.

To the argument urged in favour of the Corporation and Test acts, founded on the apprehension that if they were repealed, the dissenters might become a majority of the people, Mr. Fox gives a brief reply, *viz.* that if the majority of the people of England should ever be for the abolition of the established church, then it ought to be abolished. It has been said, that by manifesting indulgence to other sects,
a candid

TEST-ACT.

a candid respect for their opinions, and a desire to promote mutual charity and good-will, the established church will be most likely to secure its stability and its honour. Whilst the grievances of persons of a different profession are redressed, and they are admitted to a participation of their civil rights, the church need not fear any combination for sapping its foundation, or for depriving it of its peculiar and distinguishing honours or emoluments. Men who are aggrieved, under a sense of what they conceive to be an indignity and injury, are the most likely to manifest hostility against an ecclesiastical establishment that engrosses all civil and secular advantages to itself.

It has been said, that it would conduce to the honour of the rulers and dignitaries of the church, if they would concur in abolishing laws which perpetuate the perversion and profanation of a religious institution:—an institution which certainly was not intended by its divine founder for the attainment and promotion of any selfish and secular purposes. *Here*, it is maintained, if any where, a line of separation should be drawn between religious and civil policy; nor should the performance of a Christian duty be made an indispensable qualification for a secular office. The dissenters, says a well-informed member of the legislature (Mr. W. Smith), who, being himself one of them, is thoroughly acquainted with their principles and character, would equally object to receiving the sacrament *as a test* in their own places of worship, though many of them would not scruple to partake of it with their brethren of the establishment, and according to their form, when considered only in its true light, as a religious duty, and an expression of Christian charity. The writer of this article is acquainted with several conscientious and avowed members of the established church, who lament this abuse of a Christian ordinance, and who wish, for the purity and honour of the church to which they are attached, that the laws imposing this test were repealed. It would likewise contribute to the satisfaction of scrupulous ministers of the established church, to be released from the obligation of administering the sacrament, as a qualification for office abstractedly considered, and more especially to persons of known licentiousness of principles and conduct. By the duties of his function, by the positive precepts of his religion, and by the rubric or canons of the church, the minister is enjoined to warn from the sacred table all blasphemers of God, all slanderers of his word, all adulterers, and all persons of a profligate life; and yet to these very persons, if they demand it as a qualification, he is compelled, by the Test act, to administer the sacrament; and if he refuses, a ruinous prosecution for damages is the obvious and inevitable consequence. On the other hand it has been said, that if the minister's conviction of profligacy of conduct is supported by all the circumstances which constitute legal proof, he may lawfully refuse the sacrament. The truth of this opinion is doubtful; but it is certain, that if he should fail in that proof, his ruin is inevitable: and if he should succeed, it is almost equally certain; for the expences of his suit will devour his scanty means, and probably consign him to a prison for his life. Allowing that any notorious evil-doer, offering himself to receive the sacrament, might be rejected by the minister, without becoming liable to any punishment, let it be considered what is the situation in which A or B, or the person who upon application to a minister had been refused the sacrament, was placed: from that moment he had incurred the penalties of the act, and was punished in a manner perfectly new, unexampled, and unauthorized by the laws of the land; he was convicted without a trial by jury, and was disabled from enjoying an office which his majesty, in the legal exercise of his prerogative, had thought proper to confer on him; and a person was thereby absolutely put into

the hands of the clergy, who were to be the great arbitrators of qualification or disqualification for offices, and places of power and emolument. Some have attempted to justify the legal establishment of the profanation of a religious institution, by comparing it with those provisions of our law which enjoin the sanction of an oath; but this argument has been considered as inapplicable to the present case, and altogether unavailing; for though it be indeed true that the legislature, by compelling every petty officer of the revenue, and every collector of a turnpike toll, to swear deeply on his admission into office, has made the crime of perjury more common, at this time, in England, than it ever appears to have been in any other age or country: yet how does the frequent commission of this crime *against* law, justify the establishment of a religious profanation *by* law? But, without any comment on the folly of pleading for a legislative debasement of religion in one way, by shewing that the legislature has contributed to its debasement in another, let it be asked, what resemblance the sacrament of the Lord's supper, which is merely a religious institution, bears to the ceremony of an oath, which is an institution so entirely political, that it answers none of the purposes of religion, promotes none of her interests, forms no part of her establishment, and belongs as much to the Jew, the Mahometan, and the idolater, as it does to the Christian. The difference, says Mr. W. Smith, between the sacrament, used as a test for office, and an oath, as a test of truth, is too obvious to escape the most careless observer. An oath was neither primarily, nor at all, an act of worship; nor, though it necessarily supposed a belief in a supreme moral governor, was it ever used as a test of particular religious opinions: the sole object to which it was directed was the attainment of truth, (with respect either to the past or the future,) where other means were insufficient,—an appeal to a Being who, by the supposition, must be acquainted with all the circumstances, and must also be both able and inclined to punish falsehood in such cases, as an insult added to a crime, was perfectly well calculated to attain the proposed end, and inapplicable to any other purpose.

If, says Mr. Fox, in concurrence with some previous observations of Mr. Beaufoy, when a man is seen going to take the sacrament, it should be asked, “is this man going to make his peace with God, and to repent him of his sins?” the answer should be, “No; he is only going there, because he has lately received the appointment of first lord of the treasury;” can any circumstance afford a greater proof of the indecency resulting from the practice of so qualifying?

Some have contended, that to grant a remission in favour of Scotland of the Test and Corporation acts, would be a breach of the union; an opinion which supposes, that because, by the articles of union, nothing can be *taken* from Scotland but what was then stipulated, therefore nothing can be *given*. Others say, that as the Test and Corporation acts are among the statutes which secure the doctrines, discipline, worship, and government of the established church of England, they are therefore by the act of union declared to be unalterable. In reply to this mode of arguing it has been observed, that the government and discipline, the doctrines and the worship of the English church, were the same before the statutes were enacted, and would continue the same if those statutes were repealed; and consequently do not derive their security from them: whereas the act which relates to the patronage of the church of Scotland, and which *did* seem to affect its discipline, was held to be no breach of the articles of union; neither was that union understood to be weakened by the subsequent act, which gave a complete toleration in Scotland to episcopal dissenters.

When the articles of union were under the consideration of parliament, a proposal was made in the house of lords, that

that the perpetual continuance of the Test act; and in the house of commons, that the perpetual continuance of the Corporation act, should be declared a fundamental condition of the intended union: but the motions were both rejected; a proof that the legislature did not mean to give to them the same perpetual existence as to the act of uniformity, and to the statute that was passed in the thirteenth of Elizabeth, both of which were specifically named, as conditions of the compact, and expressly declared irrevocable.

If the test and corporation laws are deemed unalterable parts of the articles of union, it follows, of course, that every alteration in those laws must be deemed a breach of the union, and that every suspension of those laws must be considered as a suspension of the union. Now both these acts are altered, and in part repealed, by subsequent statutes, and for six months in almost every year are wholly suspended. But who will assert that the articles of union are dissolved, or that their obligation on the two countries is suspended for six months in every year? or who will deny that the same power which alters a part may alter the whole of those laws? Who will deny that the same authority which suspends a law for six months, may abolish it for ever?

In favour of the continuance of these laws it has been urged, that they have existed for many years with great advantage; but many attempts have been made to disprove the advantage of them, and they have repeatedly been complained of as both useless and unjust. Besides, this argument for their existence is absurd, as it tends to perpetuate every enormity that can plead the sanction of age. The horror of innovation may be felt or feigned as a bar to every improvement. It may be nevertheless asked, how have these laws subsisted? By repeated suspensions; for the indemnity bills are, with few exceptions, annual acts: and where would be the impropriety of suspending them for ever, by an act of perpetual operation. In order to silence complaints of these partial and injurious laws, it has been said that the act of indemnity, annually passed, protects from the penalties of the test and corporation laws all such persons as have offended against them. If it afford such protection, what inconvenience can arise from a repeal of the statutes themselves? Is not the constant and invariable practice of passing such a bill annually, a tacit acknowledgment that the test acts are improper or unnecessary; that the penalties, if incurred, ought not to be enforced; and therefore no man could be blamed for resorting to an indemnity, held out as a protection against punishments inflicted by laws which the legislature itself continually treated with a kind of disrespect, and which were already almost repealed in practice, though they were still preserved in the statute-book by a species of superstitious regard? The only justification for evading a statute, that can be for a moment maintained, is, when that statute notoriously ought not to remain in force; and when to evade it, on account of its nature and tendency, is meritorious. But it has been said, that the Indemnity act does not protect the dissenters from the test and corporation laws; for its only effect is, that of allowing farther time to those trespassers on the law, against whom final judgment has not been awarded. Should, for example, a prosecution have been commenced, but not concluded, the Indemnity act does not discharge the proceedings; it merely suspends them for six months; so that if the party accused does not take the sacrament before the six months allowed by the Indemnity act shall expire, the proceedings will go on, and, long before the next indemnity act will come to his relief, final judgment will be awarded against him. Thus it appears, that the Indemnity act gives no effectual protection to the dissenter, who accepts a civil office or military command;

for he who cannot take the sacrament at all, cannot take it within the time required by that act. After all, indemnity supposes criminality, and an obnoxiousness to punishment: the office and penalty are created by these statutes: repeal the laws, and indemnity becomes needless. No man would wish, if it were always practicable, to shelter himself under an act of indemnity for omitting to do what, independently of these laws, he ought not to do; or chuse to have it thought that he is less fit and able to serve his king and country than his neighbour, who does not feel the restraint of his conscientious scruples. In corporate towns and many public offices, the obligation to qualify is considered as a kind of dead letter, and an informer would be very generally thought an odious character.

As to the Corporation act, it is said to have been forced from the legislature as an act of self-defence; and this is the proper description of an act, which, after the lapse of much more than a century, when the grounds and reasons for passing it no longer existed, ought to be repealed. The question that forms the subject of this article is, in our opinion, intimately connected with the honour of the church and the prosperity of the state, as well as with the general interests of religion and liberty; and with these views of its importance, we refer the decision of it to the impartial judgment of the reader.

TEST, or *Tese*, in *Geography*, a river of England, which rises in the north-west part of Hampshire, bordering on Wiltshire, and runs into Southampton Water. Sir Henry Englefield seems inclined to think the original name was *Ant*.

TESTA, in *Antiquity*, the same with *ostracon*. See OSTRACISM.

TESTA, in *Italian Singing*. When a performer sings through the nose, the throat, or the teeth, the voice is called *voce da testa*, to distinguish it from *voce di petto*. Tosi says: "let the master attend with great care to the voice of his scholar, which, whether it be *di petto*, or *di testa*, should always come forth neat and clear, without passing through the nose, or being choaked in the throat; which are two of the most horrible defects in a singer, and past all remedy if once grown into a habit." Galliard's Transl. of Tosi on florid Song.

TESTA, PIETRO, in *Biography*, called Il Lucchese, from having been born at Lucca. His birth took place in 1611, and he was first instructed in painting by Pietro Paolini; afterwards he studied at Rome, under Domenichino and Pietro da Cortona. The principal objects of his study were antique marbles, and the remains of ancient architecture; in which employment such was his assiduity, that few vestiges of antiquity were known which had escaped his pencil. His extreme poverty made him morose and melancholy; and he made himself many enemies, by the freedom with which he spoke of the productions of other painters. From this state of trouble he was relieved by Sandrart, who found him among the ruins, and compassionating his distress, took him to his house, where he clothed and entertained him, and introduced him to the prince Juliniani, who employed him. After this he succeeded; and the great freedom and ease of his pencil procured him many patrons. Several of the churches and palaces at Rome are adorned with his productions: the best are esteemed to be those of the Death of St. Angelo, in the church of St. Martino à Monti, and of the Death of Iphigenia, in the Palazzo Spada. His works, however, are more frequently to be met with at Lucca. As a designer, Pietro Testa was unequal: he frequently tacked to antique torsos ignoble heads, and extremities copied from vulgar models. Of female beauty he appears to have been ignorant,

rant, though he adopted a character and form which are peculiar to himself. Of his compositions, generally perplexed and crowded, the best known and most correct is that of Achilles dragging Hector from the walls of Troy to the Grecian fleet. He delighted in allegoric subjects, and produced many of picturesque effect and attitudes: but, in their meaning, as obscure as the occasions to which they allude. Of expression, he only knew the extremes, grimace, or loathsomeness and horror. As a colourist, he was frequently rich and effective, harmonious and warm: and his execution bears the stamp of incredible freedom: while his chiaro-scuro is managed with great breadth and depth. His just character is that of a powerful machinist. He was drowned in the Tyber, in 1650, endeavouring to recover his hat, which the wind had blown into the water; though some suspect that he threw himself in, in a fit of dependency, to which he was prone.

He was an eminent engraver as well as a painter, and the number of his works in both arts attest his industry and ingenuity, considering the short period of his life.

TESTA, in *Botany* and *Vegetable Physiology*, is the skin of a seed or kernel, which enfolds the embryo, cotyledons, and, if present, the albumen, giving them their due shape; for this integument is perfectly formed, before they have attained any solidity or distinct organization. The skin is generally double, as may be seen in the peach, apricot, and walnut, that glutinous coat of the latter, which stains our fingers in peeling the kernel, being lined with a much finer, white and smooth membrane, technically called *membrana* by Gærtner. In true pulpy seeds, like those of *Jasminum*, a quantity of pulp is lodged between the *membrana* and the outer skin. Both these integuments burst irregularly, merely from the swelling of their contents in germination.

TESTA di Moro, in *Geography*, a small island near the E. coast of Sardinia. N. lat. 40° 45'. E. long. 9° 53'.

TESTA di Saori, a town of the island of Corsica; 7 miles N. of Bastia.

TESTA Nevilli, or *Testa de Nevil*, an ancient record kept by the king's remembrancer in the exchequer, containing the king's fees throughout the greatest part of England, with inquisitions of land escheated, and serjeanties.

It was denominated from its compiler Johan. de Nevil, one of the itinerant justices under king Henry III.

TESTA Sepia. See *CUTTLE-Fish Bone*.

TESTACEOLOGY, the science of testaceous vermes, or, in other words, of those soft and simple worms, which have a shelly or testaceous covering; whether, as in some kinds, it be sufficient to envelope and conceal the whole body, or only to cover a portion of it, as in others. The term is derived from *testa*, a shell; or we should rather wish, in order to support our definition, from *Testacea*, the name of the order of those vermes which have a shelly covering, and which, in the Gmelinian system, are thus defined: **TESTACEA**. Animalia Mollusca simplicia, domo sepius calcarea propria, obteeta.

Under this idea of its derivation, the word testaceology must be considered preferable to that of conchology, in designating the science of those bodies which have a shelly covering; because it may imply, or be understood to imply, not only the science of the shells which form the covering or habitation, but the animal also by which it is inhabited, while that of conchology might be confined to the shells alone. It must however be confessed, that, strictly speaking, the terms testaceology and conchology are synonymous, and that their application in the manner we propose, must rather be determined by the taste of the future naturalist than any positive rule we might lay down. The

science itself is but a branch of vermeology; and either the term conchology or testaceology may be applied with much propriety, at the discretion of the writer.

The term testaceology is certainly of late invention, and may in some degree be regarded rather as an innovation than amendment; for even with the definition we might be inclined to assign it, in order that it may be retained, there is still no actual difference in its meaning from the term conchology, a term which, to use the words of a writer of the last century, "comprehends the study of all animals that are testaceous, or have shelly coverings; not only those of the sea, but also those of the rivers and land;" and it has moreover an evident claim to priority, having been in use for at least the last forty years among the best English authors. Da Costa, a writer of no ordinary information, indeed appears to have assumed to himself the establishment, if not the actual invention of the term; for in his "Elements of Conchology," published in 1776, he expressly observes, "this peculiar branch of the history of nature, I shall call conchology." Many authors call it conchyliology; and this we find to be true in compliance both with the French and the Latin, the "Conchyliologie" of D'Argenville, and "Historia Conchyliorum" of Lister, two works of great celebrity, that had appeared some time before his "Elements" were published. We have thus endeavoured to prove that the terms testaceology and conchology are purely synonymous; and if any doubt remained, we might finally quote one further passage from the Elements before alluded to, in which we are distinctly told, that "the term of Conchology, applied to this branch of natural history by all authors, is quite applicable to its arrangement by the shells, and not by the fish." As we have already endeavoured to exemplify the rise, progress, and present state of the science of testaceous bodies in a very ample manner under the article **CONCHOLOGY**, and may be allowed to presume, with some little confidence, that we have therein concentrated much useful information upon this truly pleasing and very favourite science, it might be esteemed a waste of words to enter into any very considerable digression upon the same subject again; we shall therefore merely recommend a careful perusal of that article to the attention of the reader, and trust the result will be considered satisfactory.

It was indeed our wish, and we had made some general promise to that effect, that under the present article we would resume this subject, and submit the outlines of what we were induced to think an improvement upon the present prevailing arrangement; and upon this point it is now incumbent to offer a few remarks.

The most ardent admirer of the great Linnæus will readily concede to us, that the science of conchology was not one of those within the province of his deep research, or the decided contemplation of his active mind. Its introduction as a science, was necessary to complete the series of the vast chain of animated nature, the classification of which he had undertaken in his "Systema Naturæ," and it was therefore one he could not omit. But for this, it is believed, and with tolerable certainty, that he would have willingly avoided the subject altogether in the latter editions of that work, as it was in the early ones. We have already shewn, under our article **CONCHOLOGY**, the actual state in which Linnæus found the science, as handed down to him by his predecessors; and the various purposes to which he applied their labours and assistance. From a general view of the whole, there can no doubt remain that there is yet much to amend in the classification of shells, and that the subdivision of many of the genera already established into natural genera, appears desirable. It was under this persuasion that we

had intended, when writing the article TESTACEOLOGY, to have submitted our ideas as to a new and more comprehensive classification of the genera; to have pointed out the very essential distinctions that exist in shells of the same Linnæan genera; and have thence endeavoured to deduce an arrangement congenial with the characters of the respective natural genera which his artificial genera present. This we believe would have been regarded as an improvement in the classical distribution of the shell-tribe, but such an illustration does not appear, upon more mature reflection, to be admissible here. It must be apparent that no words, unaccompanied by figures, could possibly convey to the reader any adequate conception of the minute, ambiguous, and intricate essential characters, which many among the various tribes of shells present; and that such a series of plates as it would demand to illustrate a subject so very copious and diffuse, however desirable in the opinion of the naturalist, could not be appropriated, with any degree of propriety, in addition to the very costly series of plates already devoted by the Cyclopædia to this science in particular.

The series of plates which have already appeared, elucidate the whole of the Linnæan genera, and under each of those genera, a number of the more striking natural genera which appertain to them respectively. These plates are numerous, and the subjects for them have been selected with every possible attention; nor can we hesitate to think upon the whole they will be considered, without any further addition, as amply sufficient for every useful purpose of general information.

TESTACEOUS, in *Natural History*, an epithet given to those fish, which are covered with a strong, thick shell; as oysters, pearl-fish, &c.

In strictness, however, testaceous is only applied to fish whose strong and thick shells are entire; those which are soft, thin, and consist of several pieces jointed, as the lobster, &c. being called *crustaceous*.

In medicine, all preparations of shells, and substances of the like kind, are called testaceous.—Such are powders of crab's claws and eyes, pearl, &c.

Dr. Quincy, and others, suppose the virtue of all testaceous medicines to be alike; that they seldom or never enter the lacteals, but that the chief of their action is in the first passages; in which however they are of great use in absorbing acidities.

Hence they become of use in fevers, and especially in rectifying the many distempers in children, which generally owe their origin to such acidities.

TESTAMENT, TESTAMENTUM, in *Law*, a solemn and authentic act, by which a person declares his will, as to the disposal of his estate, effects, burial, &c.

Testaments, according to Justinian, and Sir Edward Coke, are so called, because they are *testatio mentis*; an etymon, says Judge Blackstone, which seems to favour too much of the conceit, it being plainly a substantive derived from the verb *testari*. The definition of the old Roman lawyers is much better than their etymology; *voluntatis nostræ iusta sententia de eo, quod quis post mortem suam fieri velit*; i. e. the legal declaration of a man's intentions, which he wills to be performed after his death. It is called *sententia*, to denote the circumspection and prudence with which it is supposed to be made; it is *voluntatis nostræ sententia*, because its efficacy depends on its declaring the testator's intention, whence in England it is emphatically styled his *will*: it is *iusta sententia*, that is, drawn, attested, and published with all due solemnities and forms of law: it is *de eo, quod quis post mortem suam fieri velit*, because a testament is of no force till after the death of the testator. Blackstone's Com. vol. ii.

A testament has no effect till after death, and is always revocable till then. As testaments are acts, of all others, the most subject to deceits, surprize, &c. it was found necessary to use all kinds of precautions to prevent the wills of the deceased from being eluded, and the weakness of dying persons from being abused. See WILL.

The most ancient testaments among the Romans were made *viva voce*, the testator declaring his will in the presence of seven witnesses; these they called *nuncupative* testaments; but the danger of trusting the will of the dead to the memory of the living soon abolished these: and all testaments were ordered to be in writing.

The French legislators thought *holographic* testaments, i. e. testaments written wholly with the testator's hand, an abundant security; but the Roman law, more severe, did not admit of testaments without farther solemnity.

The easiest, and most favourable, is the twenty-first law in the *code de testamentis*, which permits such as are unwilling to trust the secret of their testaments to others, to write it with their own hand, and to close it in the presence of seven witnesses, declaring to them, that it is their testament; after which it is to be signed by all the seven witnesses.

Otherwise, to make a solemn testament, it was required to be attested by seven witnesses, and sealed with their seals.

Yet the *military* testament was not subject to so many formalities: the soldier was supposed too much employed in defending the laws, to be subject to the trouble of knowing them. His tumultuary profession excused him from observing all the rules. See MILITARY.

Testaments, whereina fathers disposed of their estates among their children, had particular privileges, and were dispensed from most of the ordinary formalities.

TESTAMENT, *Probate of a*. See PROBATE and WILL.

TESTAMENT, *Old and New*, in *Sacred History*. The most common and general division of the canonical books of scripture, is that of the Old and New Testament. (See CANON.) The Hebrew word *Berith*, from which it is translated, properly signifies "Covenant." Accordingly St. Paul (2 Cor. iii. 6—18.), when he is shewing the superior excellence of the gospel covenant, or the dispensation by Christ above the legal covenant, or the dispensation by Moses, uses the word testament, not only for the covenant itself, but likewise for the books in which it is contained. The Hebrew term ברית, *berith*, invariably rendered covenant by our translators in the Old Testament, is uniformly translated Διαθηκη in the Septuagint; and in the writings of the apostles and evangelists, the words ἡ καινὴ διαθηκὴ are almost always rendered by our translators the New Testament. It is observed, that the Hebrew term corresponds much better to the English word "Covenant," though not in every case perfectly equivalent, than to "Testament;" and yet the word διαθηκὴ, in classical use, is more frequently rendered *Testament*. Our translators, ancient and modern, have probably been led to render it Testament, by the manner in which the author of the epistle to the Hebrews argues (ch. ix. 16, 17.), in allusion to the classical acceptance of the term. The term *New* is added to distinguish the religious institution of Jesus Christ from the *Old Covenant*, that is, the dispensation of Moses. Accordingly the two covenants are always in scripture the two dispensations, or religious institutions; that under Moses is the *Old*, and that under the Messiah is the *New*. Hence, from signifying the two religious dispensations, they came soon to denote the books in which what related to these dispensations was contained; the several writings of the

TESTAMENT.

Jews being called *ἡ παλαιὰ διαθήκη*, and the writings super-added by the apostles and evangelists, *ἡ καινὴ διαθήκη*.

The New Testament consisted very anciently of two codes or collections, called gospels and epistles. This was the case in the time of Ignatius, and also in the time of Tertullian, who distinguishes the gospels by the names of the writers, and calls them our "Digesta," or digests, in allusion, as it seems, to some collection of the Roman laws digested into order. As to the order of the several gospels, it appears, that in Tertullian's time they were disposed, at least in the African churches, according to the quality of the writers; those two occurring first which were written by apostles, and then the other two written by apostolical men. In some of the most ancient MSS. now extant, the order of the several evangelists is thus; Matthew, John, Luke, Mark. The order of the four gospels has been generally this: Matthew, Mark, Luke, John; then follow the Acts, St. Paul's epistles, the Catholic epistles, and the Revelation. It sufficiently appears, from a variety of considerations suggested by the excellent Dr. Lardner, that the books of the New Testament, consisting of a collection of sacred writings, in two parts, one called Gospel or Gospels, or Evangelicon; the other Epistles, or Apostle or Apostles, or Apostolicon, were only known, read, and made use of by Christians. (See CANON.) It has been a subject of some dispute, whether any sacred books of the New Testament have been lost; but there are many considerations, tending to satisfy us, that no sacred writings of the apostles of Christ are lost.

The four gospels, in our possession, were written for the benefit of those who would undoubtedly receive them with respect, keep them with care, and recommend them to others; and if any other such authentic histories of Jesus Christ had been written by apostles, or apostolical men, they would have been received, and preserved in like manner. The book of the Acts, which we still have, was the only authentic history of the preaching of the apostles after our Lord's ascension, which they had in their hands, or had heard of; consequently there was no other such history to be lost. The epistles of Paul, James, Peter, John, Jude, were sent to churches, people, or particular persons, who would shew them great regard when received, would carefully preserve them, and readily communicate them to others, that they might take copies of them, and use them for their establishment in religion and virtue; and if other such epistles had been written, the case would have been much the same, nor could any of them have been easily lost. Besides, the apostles and evangelists, who drew up any writings for the instruction or confirmation of Christian people, must have been careful of them. Upon the whole, we have no sufficient reasons for believing, that any sacred writings of the New Testament have been lost. All the books of the New Testament were written in Greek, except the gospel of St. Matthew, who, according to St. Jerom, first wrote in Judea in the Hebrew language. Tertullian, as well as many other ancient writers, afford us various testimonies to the integrity and genuineness of the gospels and other books of the New Testament in his time, as well as to their divine inspiration. See BIBLE.

Although the New Testament was written in Greek, an acquaintance with the Greek classics will not be found so conducive to the interpretation of it, as an acquaintance with the ancient Hebrew scriptures. The propriety of its being written in the Greek language will appear from the following historical fact. After the Macedonian conquests, and the division which the Grecian empire underwent among the commanders on the death of their chief, Greek soon

became the language of the people of rank through all the extensive dominions which had been subdued by Alexander. The persecutions with which the Jews were harassed under Antiochus Epiphanes, concurring with several other causes, occasioned the dispersion of a great part of their nation throughout the provinces of Asia Minor, Assyria, Phœnicia, Persia, Arabia, Libya, and Egypt; which dispersion was in process of time extended to Achaia, Macedonia, and Italy. The unavoidable consequence of this was in a few ages, to all those who settled in distant lands, the total loss of that dialect, which their fathers had brought out of Babylon into Palestine, excepting only amongst the learned. At length a complete version of the scriptures of the Old Testament was made into Greek; a language which was then, and continued for many ages afterwards, in far more general use than any other. (See SEPTUAGINT.) The Jews, who inhabited Grecian cities, where the oriental tongue was unknown, would be naturally anxious to obtain copies of this translation. Wherever Greek was the mother-tongue, this version would be gradually adopted into use not only in private in Jewish houses, but also in public in their schools and synagogues, for the explanation of the weekly lessons from the law and the prophets. The style of it would consequently soon become the standard of language to them with regard to religious subjects. Hence would arise a certain uniformity in phraseology and idiom among the Grecian Jews, wheresoever dispersed, in respect of their religion and sacred rites, whatever might be the particular dialects which prevailed in the places of their residence, and were used by them in conversing on ordinary matters. From the conformity and peculiarity in language now noticed, some critics, in order to distinguish the idioms of the LXX and New Testament from that of common Greek, have termed it *Hellenistic*; which see. Under that article we have intimated, that the habit which the apostles and evangelists had of reading the scriptures, and hearing them read, whether in the original or in the ancient version; would, by infecting their style, co-operate with the tendency which, as natives of Palestine, they would derive from conversation, to intermix Hebraisms and Chaldaisms in their writings. Some modern writers, whilst they have adverted to this circumstance, have defended the diction of the sacred penmen of the New Testament, and extolled it as altogether pure and elegant. Among these we may reckon Pfochenius and Blackwall, who, with this view, have made diligent researches among the writings of the ancient Greeks, for the discovery of words and phrases, which might appear to resemble what has been accounted Hebraism or Syriacism in the New Testament. Whereas the writings of the New Testament carry, in the very expression and idiom, an intrinsic and irresistible evidence of their authenticity. They are such as, in respect of style, could not but have been written by Jews, and hardly even by Jews superior in rank and education to those whose names they bear; and yet, under this homely garb, we find the most exalted sentiments, the closest reasoning, the purest morality, and the sublimest doctrine.

Abstracting from that lowest kind of beauty in language, which results from its softness and harmony, considered as an object to the ear, every excellency of style is relative, arising solely from its fitness for producing, in the mind of the hearer, the end intended by the writer. Now in this view it is evident, that a style and manner may, to readers of one denomination, convey the writer's sentiments with energy as well as perspicuity, which, to those of a different denomination, would convey them feebly, darkly, and, when judged by their rules of propriety, improperly. This seems to have been actually the case with the writers of the

New

New Testament. The language of Matthew, Mark, Luke, and John, is better adapted to the readers, for whose use the Gospels and Acts were at first composed, than the language of Plato or Demosthenes would have been.

If we would enter thoroughly into the idiom of the New Testament, we must familiarise ourselves to that of the Septuagint; and if we would enter thoroughly into the idiom of the Septuagint, we must accustom ourselves to the study, not only of the original of the Old Testament, but of the dialect spoken in Palestine between the return of the Jews from the Babylonish captivity, and the destruction of Jerusalem by the Romans; for this last, as well as the Hebrew, has affected the language both of the old Greek translation and of the New Testament.

Such is the origin and the character of the idiom, which prevails in the writings of the apostles and evangelists, and the remarkable conformity of the new revelation we have by them, though written in a different language, to the idiom of the old. It has been distinguished in the former by the name Hellenistic, not with critical accuracy, if regard be had to the derivation of the word, but with sufficient exactness, if attention be given to the application which the Hebrews made of the term Hellenist, by which they distinguished their Jewish brethren, who lived in Grecian cities and spoke Greek. It has been by some of late, after father Simon of the Oratory, more properly termed the Greek of the synagogue. It is acknowledged, that it cannot strictly be denominated a separate language, or even dialect, when the term dialect is conceived to imply peculiarities in declension and conjugation. But, with the greatest justice, it is denominated a peculiar idiom, being not only Hebrew and Chaldaic phrases put in Greek words, but even single Greek words used in senses in which they never occur in the writings of profane authors, and which can be learnt only from the extent of signification given to some Hebrew or Chaldaic word, corresponding to the Greek in its primitive and most ordinary sense. This difference in idiom constitutes a difficulty of another kind from that which is created by a difference in dialect; a difficulty much harder to be surmounted, as it does not affect the form of the words, but the meaning.

It is pertinent, however, to observe, that the above remarks on the Greek of the New Testament, do not imply that there was any thing which could be called idiomatical or vulgar in the language of our Lord himself, who taught always in his mother tongue. His apostles and evangelists, on the contrary, who wrote in Greek, were, in writing, obliged to translate the instructions received from him into a foreign language of a very different structure, and for the use of people accustomed to a peculiar idiom. The apparently respectful manner in which our Saviour was accosted by all ranks of his countrymen, and in which they spoke of his teaching, shews that he was universally considered as a person of eminent knowledge and abilities. It was the amazing success of his discourses to the people, in commanding the attention and reverence of all who heard him, which first awakened the jealousy of the scribes and Pharisees.

Although all the writers of the New Testament wrote in the idiom of the synagogue, we are not to conclude from hence, that there is no discernible diversity in their styles. As the same language admits of a variety of dialects, and even of provincial and foreign idioms, so the same dialect and the same idiom are susceptible of a variety of styles. The style of Paul has something peculiar, by which, in our opinion, there would be no difficulty in distinguishing him from any other writer. A discerning reader would not

readily confound the style of Luke with that of either of the evangelists who preceded him, Matthew or Mark; and still less would he mistake the apostle John's diction for that of any other penman of the New Testament. The same differences of style will be discovered by one who is but moderately conversant in Hebrew in the writers of the Old Testament. In it we have still greater variety than in the New. Some of the books are written in prose and some in verse: and in each, the differences between one book and another are considerable. In the book of Job, for instance, the character of the style is remarkably peculiar. What can be more dissimilar in this respect, though both are excellent in their kind, than the towering flights of the sublime Isaiah, and the plaintive strains of the pathetic Jeremiah? In the books of Scripture we can specify the concise style and the copious, the elevated and the simple, the aphoristic and the diffuse.

How this diversity of style is reconcileable with the idea of inspiration, we have attempted to shew under the article INSPIRATION. See Campbell's Prelim. Diff.

For other particulars in connection with the subject of this article, see BIBLE and CANON.

TESTAMENTARY ADOPTION. See ADOPTION.

TESTAMENTARY Causes, in Law, are those that relate to testaments, which were originally cognizable in the king's courts of common law, viz. the county-courts; and afterwards transferred to the jurisdiction of the church, by the favour of the crown, as a natural consequence of granting to the bishops the administration of intestates' effects. This spiritual jurisdiction of testamentary causes is a peculiar constitution of this island; for in almost all other (even in popish) countries, all matters testamentary are of the jurisdiction of the civil magistrate. And that this privilege is enjoyed by the clergy in England not as a matter of ecclesiastical right, but by the special favour and indulgence of the municipal law, and as it should seem by some public act of the great council, is freely acknowledged by Lindewode, the ablest canonist of the fifteenth century; and about a century before, in a canon of archbishop Stratford; also by the constitutions of cardinal Othobon; and likewise by archbishop Parker, in the time of queen Elizabeth. At what period of time the ecclesiastical jurisdiction of testaments and intestacies began in England, is not ascertained by any ancient writer. It appears the foreign clergy were early ambitious of this power, though they were curbed by the edict of the emperor Justin, which restrained the intimation or probate of testaments (as formerly) to the office of the *magister census*: but afterwards by the canon law it was allowed, that the bishop might compel, by ecclesiastical censures, the performance of a bequest to pious uses. And therefore it fell within the jurisdiction of the spiritual courts, by the express words of the charter of king William I. which separated those courts from the temporal. And afterwards, when king Henry I. by his coronation-charter, directed that the goods of an intestate should be divided for the good of his soul, this made all intestacies immediately spiritual causes, as much as a legacy to pious uses had been before. This therefore, says judge Blackstone, we may possibly conjecture, was the era referred to by Stratford and Othobon, when the king, by the advice of the prelates, and with the consent of his barons, invested the church with this privilege.

This jurisdiction is principally exercised with us in the consistory courts of every diocesan bishop, or in the prerogative court of the metropolitan originally; and in the arches court, and courts of delegates by appeal. It is divisible into three branches; the probate of wills, the granting of administrations, and the suing for legacies. The two former

former of which, when no opposition is made, are granted merely *ex officio et debito iustitia*, and are then the object of what is called the voluntary, and not the contentious jurisdiction. But when a caveat is entered against proving the will or granting administration, and a suit thereupon follows, in order to determine either the validity of the testament, or who hath a right to the administration, this claim and obstruction are remedied by the sentence of the spiritual court, either by establishing the will, or granting the administration. Blackstone's Com. vol. ii. See SUBTRACTION of Legacies.

TESTAMENTARY Guardian, Succession, and Tutorage. See the substantives.

TESTAMENTO *Annexo, Administration cum.* If a testator makes his will, without naming any executors, or if he names incapable persons, or if the executors named refuse to act; in any of these cases, the ordinary must grant administration *cum testamento annexo*, to some other person.

TESTAMENTS of the Twelve Patriarchs, in *Ecclesiastical History*, a kind of apocryphal or supposititious book, in which those patriarchs are introduced, speaking their last dying words, containing predictions of things future, and rules of virtue and piety; which they deliver to their sons as a choice treasure, to be carefully preserved, and to be delivered by them to their children. We have several editions of these in Latin; they were first published in Greek, by Grabe, and from his edition republished by Fabricius; and translated into English by Mr. Whiston. Cave places the anonymous author of this book in the year 192, or nearer the beginning of the second century. They are cited by Origen, and, therefore, were probably written before his time. Grabe thinks they were written before the time of our Saviour, and afterwards interpolated by a Christian. But Mr. Whiston asserts, that they are really genuine, and one of the sacred apocryphal, or concealed books of the Old Testament. Cave supposes that this book was written by a judaizing Christian; Grabe apprehends that it was written in Hebrew: Beaufobre is of opinion that it was forged at the end of the first, or beginning of the second century, by some Christian converted from Judaism, and he suspects that the author was an Ebionite, and that he believed Jesus to be the son of Joseph and Mary. Dr. Lardner is positive that these testaments are not the real last words of the twelve patriarchs; but the clear knowledge of Christian affairs and principles shews this book to have been written, or else very much interpolated, after the publication of the Christian religion. He says, there is nothing in this work that might not have been written by a learned Jew of the second century or later, though he thinks that the author was a Christian, and well versed in the Jewish learning: and moreover he is of opinion, that he is placed early enough by Cave, at the year 192. Lardner's Works, vol. ii.

TESTATOR, or TESTATRIX, the person who makes his or her will and testament.

M. Gillet shews, that a person incapable of a legacy cannot demand any sum which the testator in his testament declares himself indebted to him in; in regard such a declaration of debt is presumed a fraud against the intention of the law.

TESTATUM, in *Law*, a writ in personal actions; where, if the defendant cannot be arrested on a *capias* in the county where the action is laid, but is returned *non est inventus* by the sheriff, this writ shall be sent into any other county, where such person is thought to be, or to have wherewithal to satisfy the demand.

It is called *testatum*, because the sheriff has before testified, that the defendant was not to be found in his bailiwick.

TESTE, a term commonly used in the close of a writ, where the date is contained, which begins with *Teste meipso*, if it be an original writ; or, if judicial, *Teste, the lord chief justice*, &c. according to the court whence it comes. In some ancient formulas, we read *Teste castro Angliæ*. There must be at least fifteen days between the teste and return of every process awarded from the king's bench into any foreign county. See WRIT.

TESTENICH, in *Geography*, a small island in the gulf of Venice. N. lat. 44° 54'. E. long. 14° 47'.

TESTER. See TESTON.

TESTES, TESTICULI, in *Anatomy*; quia virilitatem testantur; glandular bodies, peculiar to the male sex of animals, serving the office of secreting the fecundating fluid: hence their removal deprives an animal of the power of propagating its kind. See GENERATION, *Male Organs of*.

The testes are wanting in most of the fish kind. The spinose fishes in general have neither testes nor parastatæ; but all the cetaceous fishes have them, and not a few of the cartilaginous kinds. Those fish that have them, have always two, as in land-animals; but they differ much in figure and situation in the several kinds, particularly in the whale and flat-fish. See *Anatomy of FISH*.

TESTES of the Brain, two small hemispherical eminences, situated at the posterior and inferior aspect of the optic thalami, and now more generally known, together with two very similar ones immediately above them, by the name of tubercula quadrigemina. See BRAIN.

TESTES Synodales. See SYNODALES.

TESTI, FULVIO, *Count*, in *Biography*, an Italian poet, was born in 1593, at Ferrara, and settling, when young, at Modena, he rose to the highest offices and honours of the state. Nevertheless, alternate prosperity and adversity visited him: inconstant and ambitious, he fell into disgrace with Francis I. who imprisoned him in the citadel of Modena, where he died in 1646. His poems are chiefly of the lyric class. The productions of his maturer judgment are distinguished above those of his contemporaries for vigour and poetical spirit; and some of them, with respect to elevation of sentiment and beauty of imagery, will bear comparison with the productions of the best Italian poets. He also attempted tragedy in two compositions, intitled "Arinda," and "L'Isola d'Alcina;" but their style is lyric rather than dramatic composition. Tiraboschi. Gen. Biog.

TESTIBUS HIIS. See HIIS.

TESTICLE, TESTIS, in *Anatomy*. See GENERATION.

TESTICLE, *Diseased*, in *Surgery*. See SARCOCELE, HYDROCELE, FUNGUS of the Testicle, FUNGUS Hamatodes, HERNIA Humoralis, &c.

TESTICLE, *Operation of removing*. See CASTRATION.

TESTIGOS, LOS, in *Geography*, a cluster of small islands, about ten leagues from the continent of South America, and the same distance from the island of Grenada. N. lat. 11° 45'. W. long. 62° 5'.

TESTIMON, a town of Prussia, in the province of Ermeland; 16 miles S.S.E. of Hillsberg.

TESTIMONIAL, a kind of certificate, signed either by the master and fellows of the college, where a person last resided, or by three, at least, reverend divines, who knew him well for three years last past; giving an account of the conduct and learning of the person.

Such a testimonial is always required before holy orders are conferred; and the bishop even ordinarily demands one of a priest before he admits him to a benefice.

TESTIMONIAL is also a certificate under the hand of a justice of peace, testifying the time and place when and where

a soldier or mariner landed, and the place of his dwelling, and whither he is to pass.

TESTIMONY. See **EVIDENCE**.

Testimony is a serious intimation from another of any fact or observation, as being what he remembers to have seen, heard, or experienced. The evidence of testimony is either oral or written. Some have unreasonably supposed, that this kind of evidence is solely and originally derived from experience. With regard to this it may be observed, that the evidence of testimony is to be considered as strictly logical, no farther than human veracity, in general, or the veracity of witnesses of such a character, and in such circumstances in particular, is supported, or hath not been refuted by experience. But that testimony, antecedently to experience, hath a natural influence on belief, is undeniable, in which respect it resembles memory. And in what regards single facts, it is a more adequate evidence than any conclusions from experience. When experience is applied to the discovery of the truth in a particular incident, the evidence is called *presumptive*; whereas ample testimony is accounted a positive proof of the fact. Testimony is capable of giving us absolute certainty even of the most miraculous fact, or of what is contrary to uniform experience. To this, when we have no positive reasons of mistrust or doubt, we are, by an original principle of our nature (analogous to that which compels our faith in memory), led to give an unlimited assent. As on memory alone is founded the merely personal experience of the individual, so on testimony, in concurrence with memory, is founded the much more extensive experience, which is not originally our own, but derived from others. See on this subject Campbell's *Philos. of Rhet.* vol. i. book i. chap. 5. and *Dissertation on Miracles*, part i. sect. i. and i. See **FAITH**.

For the credibility of human testimony, see **CERTITUDE**.

TESTINA, in *Ancient Geography*, a town of Italy, belonging to the Sabines, placed by D'Anville S.W. of Amitemum.

TESTING, in *Metallurgy*, denotes the operation of refining large quantities of gold and silver, by means of lead, in the vessel called a *test*. This operation is performed by the destruction, vitrification, and scorification of all the extraneous and destructible metallic substances with which those noble metals are alloyed. It consists in adding to the alloyed gold and silver, a certain quantity of lead, and in exposing afterwards this mass to the action of the fire. The lead, by increasing the proportion of imperfect metals, prevents them from being so well covered and protected by the perfect metals; by uniting with these, it communicates to them a property it has of losing very easily a great part of its inflammable principle; and lastly, by its vitrifying and fusing property, which it exercises with all its force upon the calcined and naturally refractory parts of the other metals, it facilitates and accelerates the fusion, the scorification, and separation of these metals. The lead, which in this operation is purified, and scorifies along with it the imperfect metals, separates from the metallic mass with which it is then incapable of remaining united: it floats upon the surface of the melted mass; because by losing part of its phlogiston, (according to the former language of chemists,) it loses also part of its specific gravity, and lastly it vitrifies. The removal of the vitrified matter in the process is procured either by the nature of the vessel in which the melted matter is contained, and which, being porous, absorbs and imbibes the scorified matter as fast as it is formed; or by a channel cut in the edge of the vessel through which the matter flows out.

The process of testing is generally performed in the same manner as that of cupellation. See **ASSAYING** and **COPELLING**.

But when great quantities of base metal are to be worked off from a little gold, recourse is had to a more expeditious method, that of testing before the bellows. An oval test is placed in a cavity, made in a hearth of a convenient height, and some moistened sand or ashes pressed round it to keep it steady: the nose of a bellows is directed along its surface, in such a manner, that if ashes are sprinkled in the cavity of the test, the bellows may blow them completely out; some have an iron plate fixed before the bellows, to direct the blast downwards. To keep the surface of the test from being injured in putting in the metal, some cloths or pieces of paper are interposed. The fuel consists of billets of barked oak, laid on the sides of the test, with others laid cross-wise on these: the bellows impels the flame on the metal, clears the surface of ashes or sparks of coal, hastens the scorification of the lead, and blows off the scoria, as fast as it is formed, to one end of the test, where it runs out through a notch made for that purpose. About two-thirds of the scorified lead may be thus collected; the rest being partly absorbed by the test, and partly dissipated by the action of the bellows. Care must be taken not to urge the blast too strongly, lest some portion of the gold should be carried away by the fumes impetuously forced off from the lead, and some minute particles of it entangled and blown off with the scoria. *Macquer's Chem. Dict. Art. Refining.* Lewis's *Ph. Techn.* p. 146.

TESTO, Ital. literally *test*. In *Music* it implies a subject, or words of a song, or other vocal composition, to which some air, melody, or harmony, is to be composed.

It is a matter of great concern to understand well how to appropriate or adapt the music to the words of a song, to express the sense, and make a just application of the long and short syllables to the notes and time with which they are to be connected.

But this branch of the science, which depends greatly on the knowledge of poetry, has lain a long time almost unregarded; and even at present, very little care is taken in this point in the modern music, which is somewhat wonderful, since it was to this that the ancients attributed the extraordinary effects of their music; for by them this branch was most accurately observed, and by this they regulated and governed their measures, so that they might produce the desired effects; and some philosophers say, the human passions and affections. *Vossius de Poem. Cantu*, &c.

TESTON, **TESTER**, the name of a coin struck in France by Louis XII. in 1513, and in Scotland in the time of Francis II. and Mary queen of Scotland, so called from the head of the king, (*teste* or *tête*;) which was engraved upon it. The silver it contained was 11 deniers 18 grains; its weight, 7 deniers 11 $\frac{1}{2}$ grains; and its value 10 sols. The coinage of it was prohibited by Henry III. in 1575, when the value of it was augmented to 14 sols 6 deniers. *Encycl.*

A remarkable Scottish medal of this kind was that inaugurative of Francis II. of France with Mary of Scotland, though it is more properly indeed French, being, as it is thought, struck upon their coronation, as being a queen of that country. It presents busts of Francis and Mary, face to face, with three legends around them, the outermost of which contains their titles, the middle one this singular sentence,

“Which wonders how the devil it got there:”

HORA NONA DOMINUS IHS EXPIRAVIT HELLI CLAMANS, a most ominous motto, one would imagine, to a superstitious ear. The innermost legend is only the name of the city of Paris. There are fine French testoons of Francis and Mary, likewise presenting them face to face, with the arms of France

France and Scotland upon the reverse, as is also the case of the medal just mentioned. These pieces are so fine and rare, that Dr. Hunter gave ten guineas for the one in his cabinet, which contains as vast and well-chosen a private collection, of all sorts of coins and medals, as any in the world.

Testoons, or shillings, were first coined in Scotland about the year 1553, and they bore the bust of the queen and the arms of France and Scotland on the reverse: they were of the same intrinsic value with those of England, and were worth four shillings; the half-testoon two, Scottish money. The silver testoon of Mary, chiefly of 1553 or 1562, with her bust, are rare, worth about 30s.; half still more rare, valued at 3*l*. Pinkerton on Medals.

The teston, testoon, or tester, among us, succeeded the groat, which was introduced by Edward III. in 1354. It was also called shilling, and first coined by Henry VII. in 1503; and was rated at 12*d*. in the reign of Henry VIII. and afterwards reduced to 6*d*. The testoon of the first year of Edward VI. is extremely rare.

TESTOON, or TESTONE, a silver coin in Italy, and also in Portugal. At Florence, the testoon, or testone, as a money of account and a silver coin, is worth two lire, or three paoli. The testoon is a money of account at Lisbon, and is valued at 100 rees. And of the gold coins struck since 1722, there are the Dezeséis testoon of 1600 rees, and the Oito testoon of 800 rees. The silver coins are testoons of 100 and halves of 50 rees.

At Rome the scudo, as a money of account, is divided into 3½ testoni; and among the silver coins, the testoni are valued at 3 paoli, the paoli being worth 5¼*d*. sterling nearly. See COIN.

TESTORE, CARLO GIOVANNI, in *Biography*, a violinist and music-master, resident at Versailles in 1770. In 1767 he published a treatise on music, entitled, "Musica ragionata," in 4to. This author was perhaps the first Italian who adopted Rameau's principles. He simplified his rules, and made his treatise more intelligible to *principiante* than Rameau himself, or his scientific commentator d'Alembert. The full title of his book is "La Musica ragionata espressa familiarmente in dodici Passeggiate a Dialogo, ornati 140 essempli Musicali in rami."

TESTOURE, in *Geography*, a town of Africa, in the country of Tunis, on the Mejerdah; 40 miles S.W. of Tunis.

TESTUDO, in *Antiquity*, was particularly used among the poets, &c. for the ancient lyre, or lyre of Amphion; because it was said to have been originally made, by its inventor Mercury, of the back or hollow shell of a testudo aquatica, or sea-tortoise, which he accidentally found on the banks of the river Nile.

Mr. Molyneux has an express discourse, in the Philosophical Transactions, to shew that the tortoise-shell was the basis of the ancient lyre, and that the whole instrument had thence the denomination testudo; which account throws some light on an obscure passage in Horace, ode iii. lib. 4. mistaken by all the commentators:

"O, testudinis aureæ
Dulcem quæ strepitum, Pieri, temperas!
O mutis quoque piscibus
Donatura cygni, si libeat, sonum!"

TESTUDO, *Tortoise*, in the *Military Art of the Ancients*, was a kind of cover, or screen, which the soldiers, *e. gr.* a whole company, made themselves of their targets, by holding them up over their heads, and standing close to each other.

Thus, if we suppose the first rank to have stood upright

on their feet; and the rest to have stooped lower and lower by degrees, till the last rank kneeled down on their knees, so that every rank covering with their targets the heads of all in the rank before them, they represented a tortoise-shell, or a sort of sloping roof.

This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above when they went to the assault. It was also used in field-battles as well as in sieges.

TESTUDO was also a kind of large defensive engine, of an oval figure, composed of boards, and wattled up at the sides with wicker, which moved on several wheels, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

TESTUDO, in *Medicine*, denotes a soft broad tumour, or gathering of impure humours between the skull and the skin, called also *talpa*, as resembling the subterraneous windings of the tortoise or mole.

TESTUDO, *Tortoise*, in *Zoology*, a genus of animals of the class of Amphibia and order of Reptiles; the generic characters of which are, that the body is furnished with a tail, and defended by a bony or coriaceous integument above and below, or above by scales; and that the upper mandible of the mouth closes over the lower; without distinct or proper teeth, the teeth, as they are called in the generality of tortoises, being no other than the serratures of the mandibles.

Gmelin enumerates thirty-three species, which are distributed into the three classes of *marine*, *fluvialile*, and *land* tortoises.

A. *Marine Tortoises, or Turtles with pinniform Feet, the former being longer.*

The animals of this class are distinguished from the land tortoises by their very large and long fin-shaped feet, in which are inclosed the bones of the toes, the first and second on each foot being furnished with visible or projecting claws, the others not appearing beyond the edge. The shield, as in the land tortoises, consists of a strong bony covering, in which are imbedded the ribs, and which is coated externally by hard horny plates, in one or two species much thicker and stronger than those of the land tortoises. Mr. Schœpf, cited by Dr. Shaw, observes, that the apparent number of claws or projecting extremities on the feet of the marine tortoises, appears to be no certain criterion of the species; but, on the contrary, is found to vary so as to contradict the Linnæan specific characters.

Species.

CORIACEA; Coriaceous Tortoise. Striated lengthwise; or brown turtle, paler beneath, with coriaceous shell, marked by five longitudinal tuberculated ribs. This is the largest of the marine tortoises, being found eight feet long, and one thousand pounds in weight. It is larger than others of its tribe, and its external covering differs by not being horny, but resembling strong leather, marked over the surface into small, obscurely subhexagonal and pentagonal divisions, without destroying its general smoothness. The longitudinal ribs or ridges are five; and comprehending those that border the sides, the number is seven. It has no under or thoracic shell; the head is large, and the upper mandible notched at the tip, so as to exhibit the appearance of two large teeth, between which, when the mouth is closed, is received the tip of the lower mandibles; the fins are large and long, and covered with a tough leathery skin; the tail is rather short and sharp-pointed. This species is a native of the Mediterranean, and has occasionally been taken on the coasts both of France and England. It is also found, not only in the European

ropean seas, but in those of South America, and about some of the African coasts. The Greeks, according to Cæpède, were well acquainted with this specimen, and used it in the construction of the lyre or harp. (See TESTUDO, in *Antiquity*.) Pennant says, that this species is extremely fat, but the flesh coarse and bad; but the Carthufians will eat no other species. The small sea tortoise described by Pennant in the *Phil. Trans.* for 1771, is said to be the young of this animal. Gmelin mentions this and another as varieties.

IMBRICATA. The imbricated or variegated turtle with thirteen imbricated scales on the disk; these lap over each other at the extremities like tiles on the roof of a building. The head is smaller than in other turtles; the neck longer; and the beak narrower, sharper, and more curved, so as considerably to resemble the bill of a hawk, and from this circumstance the animal derives its popular name of the "hawkbill turtle." This turtle is a native of the Asiatic and American seas, and is sometimes found in the Mediterranean. It has been often known to measure five feet in length, and to weigh 500 or 600 pounds. In the Indian ocean it attains a prodigious size. Its shell was anciently used for a shield, and still serves for that purpose among barbarous nations. The flesh is not esteemed as a food; the lamellæ or plates of the shell, being much stronger, thicker, and clearer than those of any other kind, constitute its sole value. See *TORTOISE-Shell*.

MYLAS. Brownish turtle, with thirteen scales on the disk; the green turtle of some writers, with two nails on the fore-feet, and single ones on the hind-feet. This common green turtle (excellent turtle), is so named from the green tinge, derived from the vegetable substances on which it feeds, often exhibited by its fat, when the animal is in its highest perfection. It is one of the largest of this genus, often measuring above five feet in length (sometimes more than six), and weighing more than 500 or 600 pounds. Its colour is a dull palish brown, variegated with deeper undulations; but not exhibiting the beautiful colours which distinguish the *T. imbricata*. Its flesh, however, is in such estimation, that the inhabitants of the West Indian islands have long considered it as one of the most excellent articles of food, and have introduced a similar taste into some of the European nations. In our own country it is much esteemed, and considerable quantities of it are imported to supply the luxury of the metropolis. Its introduction, however, cannot be traced farther than about 50 or 60 years backward. Sir Hans Sloane informs us, in his *History of Jamaica*, that forty sloops were employed by the inhabitants of Port Royal, in Jamaica, for catching them, and that the markets there are supplied with turtle as ours are with butcher's meat. The method of taking them at the Bahama islands is by striking them with a small iron peg two inches long, put in a socket at the end of a staff twelve feet long. Two men usually set out for this work in a little light boat or canoe, one to row and gently steer the boat, while the other stands at the head of it with his striker. The turtle are sometimes discovered by their swimming with their head and back out of the water, but they are oftener discovered lying at the bottom, a fathom or more deep. If a turtle perceives he is discovered, he starts up to make his escape, the men in the boat pursuing him, endeavour to keep sight of him, which they often lose, and recover again by the turtle putting his nose out of the water to breathe: thus they pursue him, one paddling or rowing, while the other stands ready with his striker. It is sometimes half an hour before he is tired; then he sinks at once to the bottom, which gives them an opportunity of striking him, which is by piercing him with an iron peg, which slips

out of the socket, but is fastened with a string to the pole. If he is spent and tired by being long pursued, he tamely submits, when struck, to be taken into the boat or hauled ashore. There are men who by diving will get on their backs, and by pressing down their hind parts, and raising the fore-part of them by force, bring them to the top of the water, while another slips a noose about their necks.

The sea tortoises, or turtles, says Catesby, never go on shore but to lay their eggs, which they do in April: they then crawl up from the sea above the flowing of high water, and dig a hole above two feet deep in the sand, into which they drop in one night above an hundred eggs, at which time they are so intent on Nature's work, that they regard none that approach them; but will drop their eggs into a hat, if held under them; but if they are disturbed before they begin to lay, they will forsake the place, and seek another. They lay their eggs at three, and sometimes at four different times; there being fourteen days between every time; so that they hatch and creep from their holes into the sea at different times also. When they have laid their complement of eggs, they fill the hole with sand, and leave them to be hatched by the heat of the sun, which is usually performed in about three weeks. It may be proper to add, that the eggs are about the size of tennis-balls, round, white, and covered with a smooth parchment-like skin. Gmelin mentions several varieties of this species.

CARETTA. The variegated turtle, with fifteen dorsal scales, those of the middle range gibbous towards their tips. This species is larger than any yet discovered, except perhaps the *coriacea*. It is called the "loggerhead turtle;" and though it resembles the last species, or green turtle, it is distinguished by the superior size of the head, the proportional breadth of the shell, and by its deeper and more variegated colours: but the principal distinction consists in the number of dorsal segments or scutella of the shell, which amount constantly to fifteen. The fore-feet are very large and long; the hind-feet much shorter, though broad. In a commercial view, this species is of little importance; its flesh being rank and coarse, and the laminae of the shell too thin for general use. It is said, however, to afford a good quantity of oil, which may be used for lamps, &c. This turtle is very strong and fierce, and even dangerous. It is an inhabitant of the same seas with the green turtle, but has been found in remote latitudes, even in the Mediterranean, and particularly about the coasts of Italy and Sicily.

MACROPUS. With an ovate, carinate, emarginate shield, and the feet very large and bifariously unguiculated.

B. *Fluvialtile*, with palmated feet, shell joined with the sternum by a membrane, and supported in the middle on both sides by two processes of the sternum.

ORBICULARIS. The *T. europea* of Schneider, with oval, flattish, smooth, dark brown shell, marked with very numerous yellowish specks and streaks. This speckled tortoise of the "*Naturalist's Miscellany*," or *T. meleagris*, is of small size, the shell measuring about four or five inches in length, and its disk composed of thirteen, and the margin of twenty-five pieces; the under shell whitish-yellow, tinged towards the joints with brown; the head ovate, somewhat convex above, and flattish on each side and beneath; the skin of the neck lax and wrinkly; the legs short and scaly, feet webbed, fore-feet having five toes and hinder only four; the claws on all the feet sharp-pointed, and crooked; the tail nearly half as long as the body, thin, attenuated, compressed and scaly, and also spotted like the body.

This elegant species is a native of many parts of Europe, being

TESTUDO.

being found in Italy, Sardinia, France, Hungary, Prussia, &c. inhabiting lakes and muddy waters, and feeding on aquatic plants, insects, snails, and small fish. The flesh is said to be good as food, for which purpose it is sold in the markets, and occasionally kept in ponds, and fed or fattened with lettuce-leaves, bread, &c. &c. It may be conveniently kept in a cellar and fed with oats, scattered on the floor, which it greedily eats when they begin to germinate. It deposits its eggs in sandy and funny places in the beginning of spring, which are not hatched, as it is pretended, till the succeeding spring.

MEMBRANACEA. With three claws on the feet, and shell striated on the back, membranaceous, ovate and grey. Found in the sea that washes Guiana. See *T. FEROX*.

TRIUNGUIS. With three claws on the feet, the disk of the back rugose and orbiculated, the lower border smooth, and nostrils in a cylinder elevated above and projecting beyond the head. Found rarely in the Nile, and supposed to be the same with the former.

CARTILAGINEA. Shell orbicular, membranaceous, striated on the back; three claws on the feet, and nose cylindrical and prolonged. This is the *T. Boddaerti* and a rare species. See the next article.

FEROX; Fierce Tortoise. With ovate, cartilaginous shell; three claws on the feet, and tubular, prominent nostrils. Dr. Shaw queries whether the *T. rostrata* of Schœpf, the *T.* with palmated feet, &c. of Thunberg, the *T. cartilaginea* of Boddaert, the *T. Boddaerti* of Schneider, the *T. triunguis* of Forskal, and the *T. membranacea* of Blumenberg, do not belong to this species. This is a remarkable species, and distinguished by the unusual nature of its shield, which is hard and ossous only in the middle part, while the edges gradually degenerate into a flexible coriaceous verge; obscurely marked with five or six transverse bands, and granulated with small warts or prominences, gradually enlarging as they approach the flexible edge; the head rather small, somewhat trigonal, with the snout much lengthened, and the upper part drawn out into a sub-cylindric form, terminated by the nostrils, and projecting much beyond the lower mandible; the neck, when retracted, thick, and surrounded with many folds of skin, but when exerted, equal in length to that of the whole shell; the legs short, thick, and covered with a wreathed skin; the feet furnished with strong and broad webs, connecting the three last toes of each; the three first on each foot furnished with strong claws, and the remaining ones unarmed; having, besides the proper toes, two spurious ones on the hind and one on the fore feet, strengthening and expanding the web; the tail short, pointed, and curving inwards; the eyes very small and round; the colour above deep brownish-olive, and below white; the shell marked beneath in a very elegant manner, with ramifications of vessels.

This species is found in Pennsylvania, Carolina, &c. &c.; and is possessed, differently from most others of the tribe, of considerable vigour and swiftness of motion, springing towards its assailant, when attacked, with great alacrity and fierceness; about a foot and half long, and fifteen inches broad. It was first described by Dr. Garden. Its flesh is said to be extremely delicate, being equal, if not superior, even to that of the green turtle. The great soft-billed turtle, described by Mr. Bartram in his Travels, appears to be the same with this. Found in all the rivers, lakes, and pools of East Florida, weighing from 30 to 40 pounds. The *T. rostrata* of Thunberg seems to be the young of the species above described; and the *T. triunguis* of Forskal is allied to the same species. Shaw.

SCABRA. With smooth discoloured head, and shield oval,

convex, carinated and rough. The *scabra* of Linnæus is described as having palmated feet and flattish shell, with all the intermediate scutella elevated on the back. The shell of this species is figured by Seba; it measures about two inches and a half in length, and nearly two inches in breadth; being of a cordated figure, or somewhat pointed at the bottom. Its colour is light-reddish, variegated on the head and shell with white lines and spots; the feet marked with red specks, and having each five toes with sharp claws; the head prominent, and eyes small. Shaw.

SQUAMATA; Scaly Tortoise. With ovate body, smooth beneath, but covered above, together with the neck, feet, and tail, with numerous scales. According to Bontius, in his History of Java, this singular species is an inhabitant of fresh waters, where it burrows under the banks, in order perhaps to deposit its eggs. The Javanese call it *taunab*, or the digger, and the Chinese *lary*, or the runner, a burlesque title given to it on account of its slow pace. Its flesh is said to be extremely delicate; and the Chinese use the pulverized scales dissolved in water, as a remedy in dysenteric cases and against the colic. It is said to prey on small fish. This species seems to connect the lizard and tortoise tribes. Shaw.

LUTARIA; Mud or Brown Tortoise. With flattish shell, and tail half the length of the body; carinated, says Gmelin, behind with three scutella. This species is said to be common in many parts of Europe, as well as Asia, being found in India, Japan, &c. According to Cépède, it is not more than seven or eight inches from the tip of the nose to that of the tail, and about three or four inches in breadth; the disk consists of thirteen pieces, striated and slightly punctated in the centre, and along the middle range runs a longitudinal carina; the margin consists of twenty-three pieces, bordered with slight striæ; the colour of the shell is blackish and also of the skin; the feet are webbed, with five toes before, and four behind; the exterior toe of each foot is unarmed; the tail is stretched out in walking, from which circumstance the animal has been called "*Mus aquatilis*." Like other tortoises, it sometimes utters a kind of broken hiss. This animal is common in France, and particularly in Languedoc and many parts of Provence; and in a lake, situated in the plain of Durance, such numbers were found as to supply the neighbouring peasantry for more than three months. Although this species be aquatic, it always lays its eggs on land, digging a hollow and covering them with mould. This animal is useful in a garden, which it frees from noxious animals, without doing any mischief itself. It may be domesticated, and kept in a basin or receptacle of water, so contrived on the edges as to give it a ready egress, when it wishes to wander about for prey. In fish-ponds it is destructive. Shaw. Gmelin mentions two varieties, *viz.* *T. tabulata* and *T. campanulata*.

SCORPIOIDES. See *T. FIMBRIATA*.

HERMANNI. With four claws on the feet, and the tip of the tail unguiculated. See *T. TRICARINATA*.

Gmelin mentions several varieties of this species.

CAROLINA. With digitated feet, gibbous shell, and no tail. This is the *T. clausa*, or close tortoise, of Linnæus and other writers, with blackish shell, irregularly spotted with yellow, with obtuse dorsal carina, and bivalve under-shell completely closing the upper, whence it obtains its name. The under part of the shell is so continued round the margin, that when the animal withdraws its head and legs, it is able accurately to close all parts of the shell together, so as to be perfectly secure. The defence of this little animal, which rarely exceeds four or five inches in length, is such, that it is uninjured by a weight of 500 or 600 pounds,
and

TESTUDO.

and able to walk under this heavy load. It is a native of many parts of North America, found chiefly in marshy situations, and occasionally in the driest and hottest places. It is principally sought for on account of its eggs, which are reckoned a delicacy. It feeds on small animals, as beetles, mice, and even serpents, which it draws into its shell, and crushes to death; and also on various vegetable substances.

PALUSTRIS. With depressed shell, five claws on the fore-feet, and four on the hind-feet; found in the stagnant waters of Jamaica, and seeking food in the adjoining meadows. This is the *T. terrapin* of Schæpf, and the *T. concentrica* of other writers, with sub-depressed, sub-carinated, oval yellow shell, with the scutella marked by concentric brown zones. The shell measures from four to six inches, or more. It is a native of North America, and sold in the markets at Philadelphia, and elsewhere, under the name of "Terrapin," which name is indiscriminately applied in America to several other species. It is common, as we have already said, in Jamaica, and first described by Dr. Browne, in his "History of Jamaica," who says it is a wholesome and even delicate food. In the Leverian Museum there is a large and beautiful specimen of the shell of this species. Shaw.

CASPICA. With orbicular shell, scaly head, five claws on the fore-feet, four on the hind, and naked tail. Gmelin represents it as a native of Hircania, inhabiting fresh waters, and sometimes growing to a vast size. The pieces composing the disk are sub-quadrate; those of the border parallelogrammic; the colour variegated with black and green; the lower shell blackish, spotted with white.

CLAUSA. See *T. CAROLINA*, supra.

PENNSYLVANICA. Tortoise, according to Schæpf, with smooth, elliptic, brown shell, with flattish back, the middle range of scutella sub-rhomboid and sub-imbricated, the first sub-triangular; and according to Gmelin, with five claws on the fore-feet and four on the hind, and the apex of the tail horny and acute. This is the small mud tortoise of Edwards; the shell measuring three or four inches in length. The head on the parts surrounding the jaws and eyes is of a reddish-yellow colour; the upper part, as well as the neck, legs, and tail, dusky; feet webbed; the tail small. It is a native of North America, and is found in Pennsylvania, &c. inhabiting muddy waters. When living, it is said to exhale a strong mulky odour. Mr. Schæpf mentions a variety, and another occurs in the Leverian Museum. Shaw.

SERPENTINA. The snake tortoise, characterised by Schæpf as having an ovate, depressed, triply carinated, sharp-scaled shell, rounded and acutely ferrated at the posterior margin; and by Gmelin as having digitated feet, sub-carinated shell, behind obtuse, and acutely quindentated. This is the ferrated tortoise of Pennant. It is a native of North America, inhabiting stagnant waters, growing to the weight of fifteen or twenty pounds, or more, preying on fish, ducklings, &c. seizing its prey with great force, and at the same time stretching out its neck, and hissing at the same time. The head is large, depressed, triangular, and covered with a scaly and warty skin; the orbits of the eyes are oblique; the mouth wide; the mandibles sharp; the neck covered by scaly warts; the toes distinct; the tail straight, and about two-thirds the length of the shell; and the under part of the body covered by a loose, wrinkled skin, beset with smallish soft scales and granules. This animal conceals itself in muddy water, leaving out only a part of its back, and thus appearing to be a stone or other inanimate object, more easily obtains its prey. In New York it is known by the title of the "snapping tortoise."

SPENGLERI. See *T. SERRATA*, infra.

FIMBRIATA. Tortoise, according to Bruguiere, with oval, sub-convex, triply carinated shell, sub-digitated feet, cylindrical snout, and neck fimbriated on each side. This is an animal of very singular and disagreeable appearance. The shell is about fifteen inches or more in length, and its breadth eleven; but the whole animal, from the nose to the end of the tail, is two feet three inches. The head is large and flat, rounded in front, and edged on the sides with warty and wrinkled membranaceous appendages, about five inches wide, and covered behind by a three-lobed prominence; the nose resembles a proboscis, cylindrical, ten lines long, truncated, pierced by the nostrils, at the tip, where they are separated by a cartilaginous division; the eyes are round, seated at the base of the proboscis, and ten lines distant from each other; the mandibles are equal in length, and entire; the gape of the mouth is wide; the neck seven inches long, and four and a half broad; above flat and warty, and furnished on each side with six fimbriated membranaceous appendages disposed lengthwise, and alternately larger and smaller; the under part of the neck is beset with four similar appendages, placed opposite to the two on the head, and increased by two longitudinal wrinkles: the fore-feet are scaly and warty, having five indistinct toes, with as many longish sharp claws, convex above and flat beneath; the hind-feet are also scaly, with less distinct toes, having four claws, the fifth toe being unarmed, and very short: the tail is an inch long, bent slightly, and covered with a granulated skin; all the thirteen femicircular pieces, of which the shell consists, are wrinkled and irregularly notched at the hind part; the twenty-five marginal pieces are almost square, radiated on the surface with oblique wrinkles, and toothed in the interior edge. The colour of the whole is brown, somewhat paler beneath. This animal is said to be a native of Guiana, but is now rare in the rivers of Cayenne, as it has been plentifully taken by fishermen, it being considered as excellent food. It feeds on aquatic plants, and wanders by night to some distance in search of pasture. It has been suggested, but without certainty, that this is the *T. scorpioides* of Linnæus. Shaw.

PICTA. Tortoise with plane shell, marked on both sides with a double spot of a black-blueish colour; scutella surrounded with a yellow margin, and neck striated longitudinally with yellow and black; or tortoise with oblong, slightly convex, smooth, brown shell, with the scutella bordered with yellow. This is the cinereous tortoise of Brown's Zoology, and sufficiently distinguished from all others by the remarkable colours of the shield. This is a fresh-water species, and inhabits slow and deep rivers in North America, and should have been referred by Gmelin to his second class. In clear sunny weather these animals are said to assemble in multitudes, sitting on the fallen trunks of trees, stones, &c. and immediately plunging into the water on the least disturbance. They are said to swim very swiftly, but to walk slowly; to be able to continue many hours entirely beneath the water, but not to survive many days if kept out of their favourite element. They are very voracious, destroying ducklings, &c. which they seize by the feet, and drag under water. They are sometimes used as a food. The colour, as has been above observed, varies; being sometimes of a blackish-brown, at other times of a reddish-chestnut: the yellow markings are also either pale or deep in different individuals, and sometimes whitish; the inferior, or under edges of the upper shell, as well as the upper edges, or commissures of the lower, are elegantly streaked with black, as if artificially painted, and this variegation is continued over the skin of the sides of the body. Shaw.

GUTTATA. Tortoise spotted, with oblong, moderately

TESTUDO.

convex, smooth, brown shell, with scattered yellow spots. This is *T. punctata* of Schœpf. It is a rather small species, and a native of North America, inhabiting rivers and lakes. The young are scarcely larger than pigeon's eggs, and are very black, beautifully spotted with gold colour.

LONGICOLLIS; Long-necked Tortoise. Smooth, ovate, with extremely long neck. This species is a native of New Holland, and is of the river or fresh-water kind. The colour of the whole animal above is deep olive-brown; beneath paler, and inclining to whitish. Shaw.

C. *Land tortoises, with clavated unguiculated feet, convex shell, and bony commissures joined with the sternum.*

DENTICULATA. Tortoise with sub-digitated feet, and orbicularly-cordated shell, with denticulated marginal segments. The shell is of a pale yellowish-brown colour, about four inches long and three broad, covered on the disk by broad hexagonal and pentagonal scutella, of a flattened form, with a large distinct middle space, granulated by small tubercles, and the remainder marked by five lines or furrows. The edge of the shell consists of twenty-three pieces, projecting in a serrated manner round the outline. It is supposed to be a native of North America. The feet, in Gmelin's edition of the *Systema Naturæ*, are said to be without distinct toes; and the tail short.

GRÆCA. The common land tortoise, with sub-digitated feet, hinder part of the shell gibbous, lateral margin very obtuse, and scutella flattish. Gmelin.

It is described by others as the tortoise with hemispheric black and yellow shell, gibbous behind; the pieces composing the disk convex, and the sides obtuse. This tortoise is supposed to be a native of almost all the countries bordering on the Mediterranean sea, and to be more frequent in Greece than in other regions. It is found in the European Archipelago islands, and in Corsica and Sardinia, and also in many parts of Africa. In Greece it is an article of food; the eggs are eaten boiled, and the blood is often swallowed recent. In September the animal hides itself under ground, and emerges in February: it lays its eggs in June, in a small hole on a sunny spot, out of which, after the first rains of September, the young are hatched. In England it retires about the end of October, and re-appears about the middle of April; but these seasons vary with the climate and weather, &c. The males often fight, butting at each other with a noise that may be heard at a considerable distance. This animal lives to a most extraordinary age, exceeding the period of even a century.

One of the most remarkable instances is that of a tortoise introduced into the archiepiscopal garden at Lambeth, in the time of archbishop Laud, and as near as can be collected from its history, about the year 1633, which continued to live there till the year 1753, when it was supposed to have perished rather from accidental neglect on the part of the gardener, than from the mere effect of age. This tortoise has had the honour of being commemorated by Derham, and many other writers, and its shell is preserved in the library of the palace at Lambeth.

The general manners of the tortoise, in a state of domestication in this country, are very agreeably detailed by Mr. White, in his *History of Selbourn*. "A land tortoise," says Mr. White, "which has been kept thirty years in a little walled court, retires under ground about the middle of November, and comes forth again about the middle of April. When it first appears in the spring, it discovers very little inclination for food, but in the height of summer grows voracious; and then, as the summer declines, its appetite also declines; so that for the last weeks in autumn it hardly eats

at all. Milky plants, such as lettuces, dandelions, sow-thistles, &c. are its principal food.

"The tortoise is totally a diurnal animal, and never stirs after it becomes dark. The tortoise," adds Mr. White, "like other reptiles, has an arbitrary stomach, as well as lungs, and can refrain from eating, as well as breathing, for a great part of the year. I was much taken with its sagacity, in discerning those that do it kind offices; for as soon as the good old lady comes in sight who has waited on it for more than thirty years, it hobbles towards its benefactress with awkward alacrity; but remains inattentive to strangers. Thus, not only 'the ox knoweth his owner, and the ass his master's crib,' but the most abject and torpid of beings distinguishes the hand that feeds it, and is touched with the feelings of gratitude. This creature not only goes under the earth from the middle of November to the middle of April, but sleeps great part of the summer; for it goes to bed in the longest days at four in the afternoon, and often does not stir in the morning till late. Besides, it retires to rest for every shower, and does not move at all in wet days. When one reflects on the state of this strange being, it is a matter of wonder that Providence should bestow such a seeming waste of longevity on a reptile that appears to relish it so little as to squander away more than two-thirds of its existence in a joyless stupor, and be lost to all sensation for months together in the profoundest of all slumbers! Though he loves warm weather, he avoids the hot sun; because his thick shell, when once heated, would, as the poet says of solid armour, 'scald with safety.' He therefore spends the more sultry hours under the umbrella of a large cabbage leaf, or amid the waving forests of an asparagus bed. But as he avoids heat in the summer, so in the decline of the year he improves the faint autumnal beams, by getting within the reflection of a fruit-tree wall; and though he has never read that planes inclining to the horizon receive a greater share of warmth, he inclines his shell by tilting it against the wall, to collect and admit every feeble ray."

The tortoise is said to be more tenacious of life than any other of the amphibia; many experiments performed upon them by Redi, of a cruel nature, such as opening their shells, taking out the brain, cutting off the head, evince their tenaciousness of life, and that the vital principle is very slowly discharged from these animals. Shaw.

CARINATA. Tortoise with digitated feet, and gibbous shell, with the four first dorsal scutella carinated, and entire sternum: found in warm regions, but very little known.

GEOMETRICA. Shell ovated, with all the elevated scutella above plane, marked with yellow striae issuing from the centre in form of a star: or, according to others, this is the tortoise with ovate black shell, and elevated scutella radiated with yellow; the *T. tessellata* minor of Ray. The pieces of which the disk of the shell consists are very prominent, striated, or furrowed pretty distinctly with numerous lines on their sides, and terminated above by a yellowish, flat, square, or rather hexagonal roughened space or centre, from which proceed, in a radiated direction, several well-defined yellow streaks towards the edge; thus constituting a beautiful kind of geometrical appearance on the black ground colour on which they are disposed: the marginal pieces, which are commonly twenty-four, sometimes twenty-six, in number, are also streaked with yellow, but in a somewhat different style.

The native country of this beautiful tortoise is perhaps not truly ascertained; though the shell is more frequently seen in Europe than that of almost any other kind. It is said, however, to inhabit Asia and Africa, and even to be found in America. According to Mr. Thunberg it is particularly common in shrubby places about the Cape of Good Hope. It is said to lay about twelve or fifteen eggs at a

TESTUDO.

time. The count de Cépède supposes this species to be the Terrapin of Dampier, which that navigator represents as very beautifully variegated, and as delighting in moist and marshy places; adding, that its flesh is esteemed as a food, and that it is found in plenty on the coasts of the Pine islands, between the continent of America and Cuba: they are found in the forests, where they are easily taken: the hunters mark them on the shield, and let them wander about the woods; being sure to find them again at no great distance, every one easily recognizing his own property, and afterwards carrying them to Cuba. Shaw.

PUSILLA; Little Tortoise. With sub-digitated feet, and hemispheric shell, with convex, trapezoidal scutella, friated on the margin, and punctated on the disk. This is the African land tortoise of Edwards, and thus described by him from a specimen obtained from West Barbary. "The iris of the eye is of a reddish hazel colour; the lips hard, like the bill of a bird; the head covered with scales of a yellowish colour; the neck, hind legs, and tail, covered with a flexible skin of a dirty flesh-colour; the fore-legs covered with yellow scales on their outsides, which are partly exposed when the legs are drawn in; the shell round, and pretty much rising on its upper side, and flat beneath; the pieces or compartments are of a yellowish colour, clouded and spotted with large and small irregular dusky or blackish spots, and are also furrowed or creased, the creases lessening, one within the other, till they reach the top or middle part of each: the tail is thick, scaly, and about an inch in length; and the vent is situated within the tail itself near the base: there are five claws on the fore-feet, and four on the hind, all strong, black, rather bowed, and sharp-pointed." This species is found at the Cape of Good Hope, and much resembles the *T. græca*.

INDICA. Tortoise with brown shell, reflected above the neck, and marked with a tubercle on the three upper scutella. This is the great Indian tortoise, first described by Perrault in the "History of Animals," published by the Royal Academy of France; and confounded by M. Cépède with the *T. græca*. It is found in India, on the coast of Coromandel, &c. Of this there are two varieties, one brought from the Cape of Good Hope, and another from the Southern islands.

SULCATA. Tortoise with a tail, digitated feet, gibbose shell, and scutella lined and circumscribed with a furrow; or tortoise with brown ovate shell, with furrowed scutella yellow on each side. This is one of the larger species of land tortoise, being about a foot or more in length from the nose to the tip of the tail. The shell is very convex, and has the general habit of the *græca* and *geometrica* as to shape. This species is said to be a native of the West Indies, and perhaps may be the "Hicatee" of Brown, described in his History of Jamaica. Dr. Shaw suggests that this species may be the same with *T. tabulata*.

PLANAIRIA. Tortoise with digitated feet, and shell oval, convex, and smooth. Found at Surinam.

AMERICANA TERRESTRIS. Tortoise with oval, gibbose shell; scutella yellow in the middle of the disk; the margin marked with shining, black, furrowed, lateral polygons. This is conjectured by Gmelin to be the Jaboti of the Brazilians, and the cagado of the Portuguese. Found in South America.

TABULATA. Tortoise with oblong, gibbose, brown shell, with the scutella of the disk rectangular and furrowed; with yellowish centres. This was first described and figured in Seba's "Thesaurus," and there said to be a native of Brasil, though it is believed to be rather an African species. The general length of the shell is about

five or six inches: suspected to be the same species with *T. fulcata*, supra. Shaw.

MARGINATA. Tortoise with blackish-brown, oblong, gibbose shell, variegated with yellow, widened and depressed on the hind part. The true native country of this species is not very distinctly known. Mr. Schæpf inclines to think that it is an American species. Cépède has confounded it with the *T. græca*. Shaw.

RADIATA. Tortoise with ovate black shell, and flattish scutella radiated with yellow. This is the great chequered tortoise-shell of Grew's Mus. Reg. It has been concluded by some persons, from a general resemblance in the pattern of the shell, and a similarity in colours, that this is the same species with *T. geometrica*, or a variety of it. But Dr. Shaw has pointed out a variety of differences between them and such as warrant our stating that the two shells are perfectly distinct. Grew, who has described this species, says that its native country is Madagascar; but Dr. Shaw suggests that it is also a native of Jamaica, and that in characters and size it agrees with the "Hicatee" tortoise mentioned in Brown's Zoology. Shaw.

RUGOSA. Tortoise wrinkled, with black wrinkled shell, mottled and variegated with yellow; with the middle dorsal pieces subpanduriform or fiddle-shaped. In the Leverian museum there is a variety, or perhaps a sexual difference of this species.

ELEGANS. Tortoise with orbicular, convex, yellow shell, with transverse, oval, brown spots. Seba has described it under the name of the *T. terrestris* Ceylonica elegans minor. Shaw.

AREOLATA. Tortoise with moderately convex shell, with subquadrangular, elevated, deeply furrowed scutella, and depressed rough areolæ. This is described by Seba under the appellation of *T. terrestris* Brasilienfis.

SERRATA. Tortoise with depressed yellowish shell, minutely freckled with dusky specks; all the scutella of the disk carinated, and the hinder margin of the shell serrated. This is supposed by Dr. Shaw to be the *T. spengleri* of Gmelin's Linnean System.

TRICARINATA. Tortoise with oval, slightly convex, shell, with entire margin, and all the scutella of the disk carinated. This species agrees, in shape and other particulars, with Linneus's description of his *T. orbicularis*. Shaw.

SCRIPTA. Tortoise with orbicular depressed shell, with all the scutella marked by variously-formed characters, and the marginal pieces spotted beneath. This is the *T. scabra* of Thunberg. Its native place is not ascertained. Shaw.

GALEATA. Tortoise with depressed oval shell, with the three middle scutella sharply carinated, and twenty-four marginal pieces. The native place of this species is not known; but it was brought to Mr. Retzius from India, and lived two years kept in fresh water: it subsisted on bread, &c. and sometimes on flies. From the beginning of October to the middle of May it remained without food, scarcely elevating its head above the water. It delighted in sunshine, and endeavoured to climb up the sides of the vessel occasionally, in order to enjoy its influence. It is doubtful, whether this be the *T. scabra* of Linneus. It is called *galeata* by Retzius, from the armed or cataphracted covering of the head. Shaw.

GRANULATA; Chagrin Tortoise. With orbicular, flattish, granulated shell, with cartilaginous border. This species seems to be allied to the *T. ferox*, having the shield furnished with a cartilaginous and flexible border. It is described by M. Cépède, and was brought from India by M. Sonnerat. Shaw.

Dr. Shaw, among the sea-tortoises or turtles, has described the

the turtle with green variegated shell, so named by the count de Cépède. These turtles are said to be found in great numbers in the Southern ocean, and about Cape Blanco, in New Spain. They also occur in the gulf of Mexico, and many of the large American rivers, both above and below the line; but they have never been discovered in the seas of the Old Continent. The flesh is said to be very delicate; and is even preferred in some places to that of the common turtle. M. Bomare is said by Cépède to have first described this species.

The "trunk turtle" is mentioned by Catesby, who says, without ever having seen it, from the report of others, that these turtles grow to a very large size, of a narrow form, but very deep, the upper shell being more convex than in other kinds of turtle. Their flesh is rank, but affords a large quantity of oil, which constitutes their value.

The "rhinoceros turtle," or *la tortue nasicornue*, has not been accurately described. Count de Cépède says, that it is a native of the American seas, and bears a general resemblance to the common or green turtle; but is distinguished by having a large soft tubercle on the tip of the snout, in which are situated the nostrils. It is eaten in the same manner as the green turtle, and is chiefly found in the equatorial regions. Shaw's General Zoology, vol. iii. pt. 1.

TESTUDO *Vesiformis Quadrabilis*, an hemispherical vault, or ceiling of a church, &c. in which four windows are so contrived, as that the rest of the vault is quadrable, or may be squared.

The determination of these windows was a problem proposed to the great mathematicians of Europe, particularly the cultivators of the new calculus differentialis, in the Acta Eruditorum Lipsiæ, by sig. Viviani, under the fictitious name of A. D. Piollæi pusillo-geometra, which was the anagram of postremo Galilæi discipulo.

It was solved by several persons, particularly M. Leibnitz, the very day he saw it: and he gave it in the Leipzig Acts in a variety of ways; as also did M. Bernouilli, the marquis de l'Hospital, Dr. Wallis, and Dr. Gregory.

TESTWOOD, in *Biography*, a singing man in the choir of Windfor, was burnt for his intemperate zeal in the cause of Protestantism, 1544, when Marbeck was likewise condemned, but afterwards pardoned.

TESZERSKEY, in *Geography*, a town of Croatia; 6 miles S.W. of Novi.

TET, a river of France, which rises in the Pyrenées, a little above Mont Louis, and runs into the Mediterranean, 7 miles E. of Perpignan.

TETANUS, in *Medicine*, a disease consisting in a spasmodic contraction of several of the muscles of voluntary motion, and more particularly of those which shut the lower jaw: and this being a constant and prominent symptom, the affection is commonly known by the name of *locked jaw*. The spasm of the muscles is of the *tonic* kind; or that in which the excessive contraction continues for a considerable time, without any interval of complete relaxation: in which respect it is opposed to *clonic* spasms, or convulsions, where the contractions and relaxations alternate in rapid succession. (See CONVULSION and SPASM.) The powers of sensation and of intellect remain unimpaired in tetanus; in which respect also it is contrasted with epilepsy.

Tetanus admits of many varieties and modifications, on which the older nosologists had founded different species of the disease. A rigidity of the muscles of the lower jaw was denominated *trismus*. When the muscles of the back were chiefly affected, the disease was termed *opisthotonos*: when those of the fore-part of the trunk, with the flexors of the

extremities, were the seat of spasm, it was called *emprosthotonos*. Sometimes, though very rarely, the spasms are confined to one side of the body only, bending it strongly to that side; a form of the disease which has been named by Sauvages *tetanus lateralis*, and by later writers, the *pleurosthotonos*, or *pleurotonos*. It was only when the spasm was almost universal, that it was considered as entitled to the appellation of *tetanus*. Of late years, however, these names have very properly been considered as expressing only varieties of one and the same affection, differing merely in severity, but arising from the same causes, and requiring the same mode of treatment. These various forms of spasm often follow one another in succession in the same case, and mark the progress of the disease through its different stages. Thus the trismus, or locked jaw, is only a part or prelude of opisthotonos and tetanus; and though it may prove fatal at this early period, the imperfect form in which the symptoms of a disease, which has been thus arrested in its course, may appear, is by no means sufficient to establish a generic difference in the disease itself. There appears, however, to be some foundation for a division of cases, according to their duration, into the acute and the protracted: the former being very little under the controul of medicine, and in almost every instance fatal; the latter being milder in its character, and often yielding, if proper means are employed for its subjugation.

Another ground of distinction among the different cases of this formidable disorder, is derived from the nature of the causes from which they have originated. The most usual causes are certain mechanical injuries to the body, more especially such as are attended with a puncture or laceration of a nerve: on other occasions, it may be the effect of the sudden application of cold, when the body has been previously overheated: and, in a few instances, it has appeared to arise spontaneously; that is, when it could not be traced to any external exciting cause whatever. Tetanus arising from wounds is, in general, slower in its progress than that which proceeds from cold; but is attended with more danger to life.

On some occasions the disease comes on suddenly, and with great violence; but more commonly the attack is gradual. It is often eight or ten days, and sometimes much longer, after the infliction of a wound, before the first symptoms of tetanus make their appearance: and this frequently happens when the effects of the injury on the part itself appear to have subsided; when the wound has healed, and no pain or uneasiness has remained. Those cases in which the disease is more slow in its approach, afford the best opportunity of tracing the natural succession of symptoms: and the first uneasy sensation which is then observed, is that of a slight stiffness in the back part of the neck and about the shoulders, which, gradually increasing, impede the rotatory motions of the head, and also its flexion forwards: so that the patient cannot look downwards, or to either side, without turning his whole body. This uneasy feeling, being chiefly felt on motion, very much resembles what occurs from rheumatism, but it is accompanied with a sense of general lassitude and debility. The rigidity now extends from the back of the neck to the muscles of the jaw, and of the root of the tongue, so that both mastication and swallowing become difficult and painful; and at length impossible. The attempt at deglutition is attended with convulsive efforts; especially when liquids are endeavoured to be swallowed. So great is the distress which accompanies these convulsions, that the patient becomes very reluctant to renew the trials, and refuses all nourishment; and it sometimes inspires him with even a dread of the sight of water.

As the disease advances, another set of symptoms appears, bringing

TETANUS.

bringing with them a considerable increase to the sufferings of the patient. A sudden and violent pain is felt shooting from the lower extremity of the sternum to the spine, in the situation of the diaphragm. These spasms recur from time to time, at short intervals; and at each recurrence, give the signal for an immediate aggravation of all the other spasms. The muscles of the neck and jaw are immediately called into violent action; the head is pulled strongly backwards; and the jaw becomes firmly clenched. These periodical accessions of spasm become more severe, and their effects more durable; so that the head continues to be in a state of retraction, and the jaw is permanently closed, the teeth being so firmly set together, as not to admit of the smallest opening. Such constitutes what may be regarded as the first stage of the disease; which sometimes takes up three or four days. At other times the disease establishes itself, with its whole train of dreadful symptoms, in a few hours; in which case the danger is imminent; as death generally takes place in from twenty-four to forty-eight hours, and the patient very rarely passes over the third day.

The continuance of the disease, if the patient survive the immediate attack, is marked by the increasing spasm of the diaphragm, which now returns every ten or fifteen minutes, and is instantly succeeded by a stronger retraction of the head, and rigidity of the muscles extending down the back, along the spine, and affecting even those of the lower extremities. Their contractions increasing in force, the body is frequently raised in the form of a bow, resting upon the head and feet alone: a state which is more particularly denominated *opisthotonos*. The countenance, as is observed by Dr. Chalmers, is pale and contracted; the mastoid, coracohyoid, and sterno-hyoid muscles, together with the others concerned in deglutition, and the deltoid and pectoral muscles, are most violently contracted, so that the shoulders are strongly raised forwards, and the arms are stretched out, or drawn across the body; but the wrists and fingers seem not to be affected. In a few seconds, a remission takes place; the shoulders and arms recline, and the inferior extremities relax; yet not so entirely, but that generally such a degree of rigidity continues, as to prevent their being bent, even when this is attempted by another person. The muscles on the sides and fore part of the neck continue still contracted, although not so strongly; but their action is overcome by the number and strength of the posterior ones; so that the contraction of the head constantly remains. The patient breathes quick for some minutes, as if he had been excessively exercised, and the pulse is small, fluttering, and irregular, but both become more calm and slow. The face is sometimes pale in the intervals, but oftener flushed; and the whole countenance expresses strong appearances of the most melancholy distress; as well on account of the terror the patient feels at the approaching paroxysm, as from the torture he has suffered from the last, of which the painful contractions he still feels perpetually remind him. He, for the most part, desires to lie still as much as possible, and to avoid all attempts at drinking, speaking, or any kind of motion; all of which are apt to occasion a return of the spasm in all its horrors. Some, indeed, are solicitous to try a change of position, in hopes of obtaining one of greater ease; but the act of turning the patient never fails to bring on an attack of the convulsion, by which the head is drawn back to the spine: and it is at length found, that the best means of avoiding this is for him to lie perfectly still on the back.

It may, in general, be observed, that the extensor muscles are affected with spasm before the flexors. In the lower extremities, indeed, both the flexor and extensor muscles are commonly at the same time affected, and keep the limbs

rigidly extended. The flexors of the head, and the muscles that pull down the lower jaw, become affected in the progress of the disease, together with the abdominal muscles; so that the belly is strongly retracted, and feels hard, like a piece of board. The spasm of these and the other flexor muscles, becoming so powerful as to balance the action of the extensors, is a circumstance that marks the advance of the disease, and may be regarded as constituting the commencement of a third stage. In this situation the body and limbs are perfectly straight and rigid, and incapable of being moved in any way; and it is to this condition that the term *tetanus* has been more especially applied. It is a state of the most exquisite suffering: the patient is on the rack from the continual recurrence of the spasm, which has scarcely any remission. The recti muscles of the abdomen often contract unequally, producing the appearance of hard balls in particular parts. The whole belly is drawn inwards, and does not yield in the least to the descent of the diaphragm in inspiration. Although the lower extremities are always rigid at this period, yet their action is so violent during the height of the paroxysms, that were it not for the standers-by, the patient would be projected feet foremost off the bed; or would, at other times, be pushed upwards with such an impetus, as to strike the head with great force against whatever might happen to be in the way. Occasionally, the flexor muscles acquire the preponderance over the extensors, and the trunk of the body is bent forwards, the chin being fixed to the breast. This is what has been called *emprosthotonos*, and occurs only in the most violent, and of course the least frequent form of the disease. It would appear from some cases reported by Sauvages, that these opposite states are disposed to alternate with one another.

In extreme cases, there are hardly any of the voluntary muscles that remain in their natural state. The face and eyes are distorted; the tongue is suddenly darted out between the teeth, and often miserably lacerated from their closing at the same moment. Even the small muscles of the ear partake of the spasmodic action, which so universally prevails in the system. While the tongue is thrust out, the muscular flesh, which is situated between the arch of the lower jaw, and the upper part of the trachea, is drawn upwards within the throat. The countenance is much contracted; a general sweat breaks out; the eyes are watery and languid; and a pale or bloody froth bubbles out from between the lips. Tetanus, in these violent forms, is, perhaps, the most painful disease that can affect the human frame. So exquisite a degree of pain would scarcely be compatible with life, were it not occasionally alluaged by the short and imperfect remissions of spasm which occur. A more continued and severe spasm, or a general convulsion, generally finishes the tragedy, and releases the unhappy victim from all his misery: or, if already too exhausted by the severity of pain to admit of this mode of termination, delirium often ensues, protects the patient by a happy insensibility to further suffering, and smooths the avenue to death, which is then preceded by a general relaxation of the spasms.

Such are the symptoms which peculiarly belong to tetanus: and it is, perhaps, the most remarkable circumstance attending the disease, that hardly any function is primarily affected, except that of muscular action. The senses and appetites are perfect and entire; the intellectual functions are undisturbed; and the natural functions proceed in their usual course. Fever is neither an essential nor a common attendant on the disease. In the first stage, when the spasm is confined to a few muscles, the pulse is not affected: it becomes accelerated only when the spasmodic actions are general,

general, and this merely in consequence, as it would appear, of the mechanical effect produced on the blood-vessels by the contractions of the muscles, which will hurry on the circulation, and throw the blood upon the heart in larger quantity than usual, rendering the pulse contracted, frequent, and irregular. The respiration is hurried from the same cause, and the temperature of the body, as might be expected, is increased in the same proportion. That these symptoms are not the effect of fever, appears from the state of the blood, which is stated to be of a looser texture than natural, and never exhibits the buffy coat, as in inflammatory diseases. This circumstance is particularly noticed by Dr. Clephane, and also by Dr. Chalmers; and the remark has often been verified by subsequent observers. On some occasions, indeed, when the disorder is very violent, the arterial actions are increased, and a febrile state prevails; and this appears to take place more frequently when the disease has originated from cold, than when it has been excited by wounds. The skin is at first natural, but, as the disease advances, is covered with a cold sweat. The tongue is always moist. Vomiting sometimes takes place early in the complaint, but it commonly subsides in the progress of it: it is even usual for the appetite of hunger to remain through the whole course of the disease; and what food can be got down appears to be sufficiently well digested. Some local effects seem to be attributable to the contractions of the abdominal muscles. The sphincter of the bladder is occasionally affected with spasm, so as to impede the discharge of urine, which is voided with pain and difficulty: at other times, its secretion is suppressed. When it can be observed, it is stated as being high-coloured, and somewhat turbid. The bowels are found to be, in every instance, obstinately costive, a state which may partly be accounted for by the effect of opiates, which are so generally administered for the cure: but which, independently of this cause, appears to be inherent in the disease itself. The bowels require the most drastic purgatives; and there is a great sense of uneasiness about the precordia. In the latter stages of this disorder, indeed, when the powers of life begin to decline from the vast expenditure of energy occasioned by the violent muscular actions, every function in the system partakes of the general disorder; the intellect gives way, and the patient sinks from exhaustion alone, if a general convulsion does not occur to hasten his end. It is mentioned by Dr. Cullen, that, in several cases, a miliary eruption has appeared upon the skin; but he expresses a doubt whether this was a symptom of the disease, or the effect of a certain treatment of it. It has not been observed, he adds, to denote either safety or danger, or to have any effect in changing the course of the distemper.

From the more violent forms of the disease, hardly any instance of recovery has been known to take place. On the other hand, the mere protraction of the symptoms is an indication of the comparative mildness of the disease. Few patients fall a sacrifice after the ninth or tenth days, which period they never could have attained, unless the violence of the complaint had in a great measure subsided. In this milder form, however, it may be prolonged several weeks; and sometimes the spasmodic disposition remains, even for months, before health is completely restored. The pulse, in these cases, continues slow and hard, and the belly bound: but if blood be drawn, it does not exhibit any difference from its usual state. Under every circumstance of recovery, indeed, the convalescent labours long under general debility, and cannot, for months, raise himself from a supine or recumbent posture without assistance, nor without pain.

Occasional deviations from the course above described are met with in different cases; but they are not of sufficient

importance to lay the foundation of any distinct variety. The most singular of these anomalies is the one recorded by Dr. (now Sir Gilbert) Blane, of a case in which tetanus prevailed to a very considerable extent, without affecting the patient with the least degree of pain. The spasms were, in this instance, accompanied with a tingling sensation, which was even rather agreeable than distressing. The case, however, terminated fatally: but to the last, no pain was experienced. In two cases mentioned by the same author, the spasms affected only the side of the body in which the wound was situated.

The result of dissections of patients who have died of tetanus, has thrown no light whatever on the nature of this terrible affection. Sometimes there are found slight effusions within the cranium: but, in general, no morbid appearance whatever can be detected in the head. There appears to be always more or less of an inflammatory appearance in the villous coat about the œsophagus and stomach in the neighbourhood of the cardia. But those who are conversant with dissections, must be well aware that these appearances are common to a great number of diseases, and are uniformly met with in every case of rapid or violent death. Besides the redness and increased vascularity of these parts, M. Larrey states that he found the pharynx and œsophagus much contracted, and covered with a viscid reddish mucus. Dr. McArthur found, in several cases, the intestines much inflamed; and in two of them a yellow waxy fluid, of a peculiar offensive smell, covering their internal surface: but whether the inflammation was primary, or only a consequence of the pressure of the abdominal muscles, which contract so violently in this disease, he is unable to decide. See *Medico-Chirurgical Transactions*, vol. vii. p. 475.

Tetanus is a disease much more prevalent in hot than in cold climates. It is comparatively a rare disease in this island; but even here, the effect of warmth in giving a predisposition to it is sufficiently observable. It is more common in the south than in the north of England, and is much more seldom met with in Scotland than in England. It is sensibly more frequent in warm than in cold seasons. In warm, and especially in tropical climates, it may be regarded as an endemic disease, appearing at all seasons, but especially during the prevalence of the greatest heats. Warmth operates by increasing the mobility of the system, while at the same time it tends to diminish the positive strength of the fibre. The sensibility to all impressions is greater in hot climates, while the power of resisting the causes of injury is lessened: hence the greater predisposition to spasmodic diseases in general. The natives of hot climates do not enjoy a greater exemption from tetanus than European settlers. Negro slaves are peculiarly liable to its attacks. It affects all ages, sexes, constitutions, and complexions; but, *ceteris paribus*, is more apt to seize upon those in whom the largest share of vital power has been bestowed upon the muscles of voluntary motion. Hence it attacks more readily the robust, and those who are accustomed to much bodily labour. Partly on this account, and partly from their being more exposed to the occasional causes of the disease, men are much more frequently the subjects of tetanus than women.

In the torrid zone, the most frequent exciting cause of tetanus is the application of cold when the body is heated. It is often induced by the alternate exposure to the scorching heat of the sun, and to the heavy showers which frequently occur in tropical regions, and produce great and sudden vicissitudes of temperature. Sleeping out of doors after a hot day, especially on damp ground, or in a situation where a stream of cool air is admitted to the body, is often followed by tetanus in hot climates. Dr. Chalmers relates that a young man chose to cut off his hair and shave his head on a

TETANUS.

warm day in March, and went to bed without a cap: but the weather changing and becoming cold in the night, he was seized with tetanus, and the next morning was found rigid with the disease. The imprudent use of the cold bath, or even a draught of cold water, when the body has been warm by exercise, has frequently brought on tetanus.

In temperate climates, on the other hand, the disease seldom arises from the application of cold; although there is one well-attested instance mentioned by Dr. Gregory in his lectures, of its occurring from this cause in Scotland: but it is more frequently the consequence of lacerated or punctured wounds, and is particularly incident to injuries of nerves, and of tendinous parts. It sometimes follows the amputation of a limb; and it would appear that wounds of the joints, particularly those of the hands or feet, are more peculiarly liable to produce tetanus. In warm countries, the slightest cut or bruise is in danger of being succeeded by this formidable malady. Hence few of those that are wounded in battle recover: and few survive any considerable operation. It has been supposed by many, that tetanus arose from the partial division of some nervous fibres, in consequence of which the undivided filaments were unequally and violently stretched: a state which would be remedied by their complete division. Experience, however, the stubborn enemy to so many hypotheses, has by no means proved favourable to this opinion. It has also been stated to be more frequently the result of wounds, which remain in a state of great irritability, without proceeding to suppuration; it does not, however, appear that this position is supported on any extensive observation. It very often happens, indeed, that tetanus shews itself when the wound was almost healed, and the dressings have been laid aside.

In the late campaigns of our armies in the peninsula of Spain and Portugal, according to the report of sir James Macgrigor, tetanus occurred in every description, and in every stage of wounds, from the slightest to the most formidable, from the healthy and the sloughing, from the incised and lacerated, from the most simple and most complicated. It occurred at uncertain periods; but it was remarked, that if it did not commence before twenty-two days from the date of the wound, the patient was safe. It terminated in the second, third, and fourth days, and even as late as the seventeenth and twentieth days, though usually it was not protracted beyond the eighth. The most rapidly fatal case that has ever been recorded, is one that we have on the authority of the late professor Robison of Edinburgh. It occurred in a negro, who was a waiter at a tavern, and who happened to scratch his thumb with the broken edge of a china plate, and who died of tetanus a quarter of an hour after this apparently slight accident.

As the acute form of traumatic tetanus, observes Dr. Dickson, is so uniformly fatal, it is of the greatest consequence to attend to whatever may assist in detecting the disease early, or in warding it off. Richerand states, that in wounds threatening convulsions and tetanus, a persevering extension of the limbs during sleep often manifests itself before any affection of the lower jaw; and we should naturally pay more attention to any admonition of this kind in punctured or extensive lacerated wounds, particularly of tendinous or ligamentous parts, especially in injuries of the feet, hands, knee-joint, back, &c. in which the disease most frequently supervenes. Some prelusive indications of danger may often be derived from the increase of pain, irritation, and restlessness, nervous twitchings, pain and difficulty in deglutition, or in turning the head; spasms, or partial rigidity of some of the voluntary muscles; pain at the scrobiculus cordis; a suppressed or vitiated state of the dis-

charge, &c. which mark the slower approaches of the disease. M. Larrey adduces several instances of tetanus, in which the wound was either dry, or afforded only a scanty ferous exudation, and where the symptoms were relieved on suppuration being re-established; and Dr. Reid, in the Edinburgh Medical and Surgical Journal for July 1815, remarks, that on removing the dressing, instead of healthy pus, the surface of the wound was covered with a darkish unhealthy looking matter, which he had in two former instances noticed as the forerunner of tetanus. A torpor of the intestines has generally been observed to precede as well as to accompany the disease. Mr. Abernethy observes, that in four cases where he inquired into the state of the bowels, the evacuations were not like feces; and he proposes as a question in investigating the cause, what is the state of the bowels between the infliction of the injury and the appearance of this dreadful malady? Dr. Parry has adduced the velocity of the circulation as an useful criterion of the danger of the disease; and observes, that if the pulse be not above 100 or 110, by the fourth or fifth day the patient almost always recovers; but if it be quickened early, that it proves fatal; and yet there are a few instances of recovery where the pulse has risen to 120 on the first day. M. Larrey remarks, that when the perspiration, which so often attends the disease, is symptomatic, it begins upon the head and extremities; and when it is critical, it occurs over the chest and abdomen: but in many cases, perspiration flows very freely without bringing relief.

We have already stated, that in some instances the source of irritation producing the disease is not obvious. Such cases of spontaneous tetanus are very rare. Dr. Willan, in his Reports, p. 289, mentions having met with an instance in a female, 32 years of age, where there had not been any previous accident or local injury whatever; and where the only circumstance, which was likely to have contributed to its production, was severe distress of mind, occurring in a frame previously debilitated.

When we reflect upon the obscurity which involves both the *ratio symptomatum* and the proximate cause of tetanic affections, we need not wonder that the practice in these disorders should still be entirely empirical. The indication of cure which is generally applicable in all diseases, namely, the removal of the exciting causes, has but little place in a morbid condition, which is the consequence of causes that in general have ceased to act, or which it is not in our power either to remove or controul. In those cases where we could suppose local irritation to be still operating, the most effectual method of counteracting its effects on the system, would obviously be to intercept all communication between the seat of the irritation and the sensorium. If, however, the disease has already established itself, and the severe symptoms have come on, it does not appear that this would succeed in arresting the course of the disorder. Experience has but too fully shewn, that the amputation of the limb from the injury of which the tetanus had arisen, will very seldom procure even a mitigation of the symptoms, if performed after a certain period from their first appearance. This plan was fully tried in our army at Toulouze, and totally failed. In some instances, however, it is said that a favourable change has ensued, and that patients have even recovered by the sacrifice of the wounded limb: and it has been remarked, that the spasms relaxed immediately on the division of the soft parts by the knife, and before the saw was applied to the bone, in order to complete the operation. It is, therefore, highly probable, that the free division of the parts above the wound, or still more certainly the amputation of the limb, would, at a certain stage of the affection,

TETANUS.

secure the patient from the approach of tetanus. But the difficulty is here to estimate the probability of the patient's having the disease, as nothing short of the certainty of its being at hand, could well justify the operation.

As it is matter of experience that an early and highly irritable and painful condition of the wound has a tendency to excite tetanus, as well as a state in which the discharge is of a peculiar unhealthy character, or is suppressed altogether, our immediate objects should be to allay as much as possible the local irritation, and to re-establish a healthy secretion of pus. Mechanical causes of irritation should as much as possible be obviated, by early attention to remove splinters of bone, balls, or other foreign bodies, that may be lodged in the wound. Poultices and soothing applications will answer the double purpose of quieting local inflammation, and bringing on healthy suppuration. The irritability of the surface may sometimes be most effectually destroyed by lunar caustic, after which, an emollient poultice may be applied. An opposite plan of treatment has been recommended by Dr. Rush, namely, that of exciting considerable inflammation in the wounded part, by epithems of turpentine, and other highly stimulating applications; which, though it may in certain cases have succeeded in preventing tetanus, does not appear to be generally applicable, and seems accordingly to have been abandoned. On the contrary, it has of late been the universal practice in the navy, to add tincture of opium to the dressings applied to wounds, with a view of preventing tetanus. With the intention of re-exciting suppuration where there is no discharge, M. Larrey recommends the application of blisters as near as possible to the wound, and adduces instances of success from this mode of treatment.

But the cure of tetanus, when once it has commenced, is to be sought for more by the use of general, than of topical remedies. The seat of the disorder has been transferred to the brain and nervous system, and our efforts must be directed to allay their inordinate actions. The plan from which theory would lead us to expect most success, is that of exciting some new action in these organs, by which their energies would be directed into some different channel, and the existing morbid action would be suspended and superseded. The remedies which exert the most powerful immediate effects in the nervous system, are accordingly found to be the most efficacious in the cure of tetanus. Opium, wine, and other highly diffusible stimuli, digitalis and other narcotics, the sudden affusion of cold water, bleeding, purging, impregnating the system with mercury, the exhibition of arsenic, of oil of turpentine, of alkalies, and of ipecacuanha, have respectively been resorted to, and with very various, and in general but limited success. The same methods from which cures have been obtained in the milder cases, generally fail to make the least impression on the disease in its severer forms. We learn from the valuable report of sir James Macgrigor, already alluded to, that there were very few, out of several hundred cases that occurred in the British armies during the late campaigns on the Peninsula, where this disease had made any progress, in which it terminated successfully, or in which remedies, however varied, seemed to have any beneficial influence.

Opium is the remedy on which reliance has most generally been placed in combating this formidable disease; and there is no doubt that in mild cases it is competent to its complete solution. But for this purpose, it is absolutely necessary that its use be begun from the earliest appearance of the symptoms; that it be given in very large doses; and that the doses be repeated at short intervals: so that the system be kept constantly under the influence of the remedy.

It is, indeed, astonishing how the system, when possessed by a strong disposition to spasm, will resist the operation of this and other remedies, which in its ordinary state would have been more than sufficient to overpower and destroy it. Patients labouring under tetanus will bear with impunity quantities of opium, that at any other time would have been certainly fatal. Instances are upon record of five, ten, and even twenty grains, being taken every two or three hours for many days, without its producing any extraordinary narcotic effects upon the sensorium. It is always, however, advisable to begin with comparatively moderate doses, such as forty or sixty drops of tincture of opium, which may be repeated at intervals of three or four hours, and increased at each repetition, till some sensible effect is produced on the spasms. It seems requisite to augment the dose rapidly, as the disease presses upon us every hour, and no time is to be lost in resisting its advances, while there is yet a chance of controuling its fury. The circumstance of the closing of the jaw, and the difficulty of deglutition, the increase of which may soon render it hardly possible to introduce medicines into the stomach, is an additional motive urging us to push our remedies before those obstacles arise. Glysters are our only resource, when it is impossible to overcome the spasm of the fauces. Opium has also been applied externally and topically to the jaws; and relief has sometimes been obtained from an opiate plaster on the masseter muscles, or behind the ears; but these are comparatively very trifling in their efficacy, and applicable only to the slightest cases, or to those in which convalescents are still affected with a recurrence of one or two local symptoms.

It is of the greatest importance in all cases of tetanus, and more especially where opium is given, to excite a proper action of the bowels, so as to allow of no stagnation of their contents. The testimony of the army physicians, as appears from the report of sir James Macgrigor, is highly in favour of a rigid perseverance in the use of purgatives, given in doses to produce a full effect daily. Dr. Forbes states, that a solution of sulphate of magnesia, in infusion of fenna, was found to answer better than any other purgative, and it was daily given in a sufficient quantity to procure a copious evacuation, which was always dark-coloured, and highly offensive: and to this practice he chiefly attributes, in one severe case, the removal of the disease. The infrequency of locked jaw in the West Indies, in the public service, of late years, is chiefly ascribed by Dr. Dickson, to the greater freedom with which purgatives have been employed, particularly since the publication of Dr. Hamilton's work on the operation of this class of remedies; an opinion which is corroborated by the testimony of various authors, as to the state of obstinate costiveness which prevails in this disease, and the offensive nature of the contents of the intestines.

For the introduction of the stimulant and tonic plan of treatment, we are chiefly indebted to Dr. Rush, who was led to adopt it from some theoretical views he entertained on the nature of tetanus, which he conceived to be essentially a disease of debility. There can be no doubt that in many cases the exhibition of wine or spirits has been attended with very good effects. Dr. Hossack, in vol. iii. of the American Medical Repository, relates several cases which were cured by large quantities of wine.

A free allowance of wine and porter after gun-shot wounds has appeared also, according to the statement of Dr. M'Arthur, to have contributed to the very small number of cases of tetanus which occurred under his care in the hospital at Barbadoes, during nearly six years of the most active period of the war. Of the numerous cases of gun-shot wounds received into the hospital, and of operations performed, during the whole

TETANUS.

whole of that period, only two instances of tetanus occurred. Bark has been given in conjunction with wine and opium; and the muriated tincture of iron has also been used with apparent advantage. The success of the tonic plan of treatment rests also on the testimonies of Dr. Wright of Jamaica, Dr. Cochrane of Nevis, and several other West Indian practitioners; and also on that of Dr. Currie of Liverpool.

The presence of an inflammatory diathesis, which occasionally accompanies the spasmodic state, presents, however, a material obstacle to the employment of the above-mentioned remedies. So much is this the case, that many physicians have recommended the free use of the lancet, particularly in the early stages of tetanus. Dr. Dickson states it as his opinion, that in a full habit, where the wound is swelled, inflamed, and painful, venesection, with free purging, and such other means as are calculated to allay the general and local irritation, afford the fairest chance of averting the danger. (See the 7th volume of the Medico-Chirurgical Transactions, part 2.) In the 6th volume of the same work, a case is detailed by Mr. Earle, in which, though it terminated fatally, bleeding was beneficial, and lessened the patient's sufferings; and in the same volume, it is also mentioned with approbation by the medical officers in the Peninsula. Dr. M'Arthur considers that he used blood-letting with evident relief in one case, in the naval hospital at Barbadoes; that the spasms were ameliorated, the disease protracted, and the morbid appearances after death were less marked in consequence. M. Larrey also adduces some examples where it produced a good effect. Mr. Guthrie gives three cases which occurred in the hospitals of St. Andero, out of many which were recorded, where venesection was the principal remedy. In the first, in which tetanus from a wound in the hand was advancing with rapidity, the patient was bled *ad deliquium* several times with good effect, calomel and diaphoretics being given at the same time, and he recovered. In the second case, the patient was bled in the same manner, with an evident amendment of the symptoms; so much so, indeed, that he suffered but little from spasm, and could open his mouth very well, when he was seized with diarrhoea, which, in the debilitated state he was in, carried him off. In the third case, of a man of a sanguine temperament, and suffering from acute tetanus, venesection pushed to the utmost totally failed.

Digitalis has been tried in the Peninsula in several cases, occasionally with good effect, though it never appears to have effected a cure. Ether, camphor, musk, and other antispasmodics, as likewise the alkalies, were also tried, and found equally unsuccessful. Castor is strongly recommended by Arataeus, but is too feeble a remedy to have any decisive influence in so violent a disorder.

The affusion of cold water has in general been attended with great benefit. It is a practice particularly recommended by Dr. Wright, in the London Medical Observations, and is sanctioned by the concurring testimonies of Dr. Cochrane, in the Medical Commentaries, and of Dr. Currie, in his Medical Reports, &c. as well as by many other practitioners. A large pailful of cold water should be thrown upon the patient every two or three hours; he is to be immediately wiped dry, and laid in bed after each affusion, and an opiate draught administered. Some remission of the spasms will in this way be generally obtained; and many instances are upon record, of complete cures being effected by perseverance in this plan. Before the introduction of this practice, the warm bath was very commonly employed; the patient, after using it, being placed in bed, without being dried, between two blankets, with a view to bring out a sweat. It does not appear, however, that this plan was attended with any general or permanent advantage; and is certainly inferior in

efficacy to the cold affusion. The cold bath, says sir James Macgrigor, in acute tetanus, is worse than useless. The use of a hot bath impregnated with potash, and a few ounces of quick-lime, has been much recommended by Dr. Stutz of Suabia in traumatic tetanus. See Medical and Physical Journal, vol. iii.

The powerful relaxing effects of tobacco given in glyster in cases of hernia and enteritis, have suggested its employment in tetanus. Mr. Earle tried it in one very acute case, in which, although it afforded a temporary alleviation from spasm, so much agitation was produced by it, that it was not persevered in. He is, however, induced to recommend the trial of a suppository made of the extract of nicotiana, and passed up into the rectum. But, according to the report of sir James Macgrigor, tobacco glysters, tried in the advanced stage of the disease, seemed to have no effect. He represents, however, the tobacco fume as deserving of further trial. A remarkable case is recorded by Dr. Phillips, in the 6th volume of the Medico-Chirurgical Transactions, in which the jaw suddenly fell, upon the exhibition of an enema with oil of turpentine.

It has been supposed that mercury thrown quickly into the system, so as to excite salivation, would prove highly serviceable in relieving the spasms, and particularly those of the muscles of the jaw. This practice was first introduced by the practitioners in the West Indies, and in particular by Drs. D. and A. Monro, and appears to have succeeded in many cases. Dr. Rush conceives that its salutary effect is connected with its inducing in the system a state of inflammatory diathesis incompatible with the spasmodic action, which it would therefore supersede. Whatever benefit, however, may have been experienced from this plan in mild cases, it completely fails in the more severe of making any impression on the disease. Dr. Emery, Mr. Guthrie, and other medical officers attached to our army in the Peninsula, after the battle of Salamanca, tried inunction of the whole body three times a day, with strong mercurial ointment, in unlimited quantity, with no degree of success. Mr. Guthrie reports, that after the battle of Toulouze, a fatal case occurred in a man strongly under the influence of mercury, which he had used previous to the action for the cure of the itch. The combination of calomel with ipecacuanha, which has been much recommended, is equally inefficacious with the other remedies, in the acute and fully formed disease. In the mild tetanus, benefit has been derived from calomel: and its operation on the bowels is always useful, and singularly so in the mild disease distinguished by the spasms coming on slowly, and continuing of the same violence; instead of their sudden accession, and their continuing with increasing violence, as happens in the acute fully formed tetanus. In this, calomel cannot be depended upon, as the patient is carried off before the medicine can have any effect.

Several remedies were formerly in vogue, of which it is hardly necessary to give any account, as they have now lost all the credit they once enjoyed. It may be sufficient to mention the Barbadoes tar, alluded to by Dr. Cullen; the colchicum autumnale, or meadow saffron, recommended by Dufresnoy; blistering, electricity, unctuous applications, partial fomentations, &c. most of which appear either to be inert, or at best very weak auxiliaries to the remedies already described.

Of late years, tetanus has been much less frequent in the West Indies, when compared with former wars. This is attributed, apparently with great reason, by Dr. Dickson, to the improvements in the medical and surgical treatment of wounds; to greater cleanliness, and more perfect ventilation; and in general to superior comforts, diet, and accom-

modation; but particularly to the greater attention paid to the state of the bowels. See *Medico-Chirurgical Transactions*, vol. vii.

TETARBOLION, in *Ancient Coinage*, the quarter-obolus, which is the most minute coin yet found, being of $2\frac{1}{2}$ grains, and its current worth a farthing and a half.

TETARIUM, in *Ancient Geography*, a town of Asia, situated in that part of Lycaonia, which Ptolemy comprehends in Galatia.

TETARTEMORION, among the *Ancients*, denotes the fourth part of the zodiac.

TETARTO-CHRUSOS, τεταρτο-χρυσος, in *Ancient Coinage*, a gold coin of Philip, Alexander, and Lyfimaachus, which was a quarter of the Philippus or χρυσος; it weighs 33 grains, and passed for 5 drachmæ of silver, 3s. 9d., now worth intrinsically 5s.

TETAVI, in *Geography*, a town of the principality of Georgia, in the province of Caket.

TETBURY, or **TEDBURY**, anciently *Teteberie*, a large and respectable market-town in the hundred of Longtree, and county of Gloucester, England, is situated 20 miles S. by E. from Gloucester, and 99 miles W. by N. from London. Its name evidently determines it to have been a military station. On the S.E. side, within the memory of many living, were traces of a strong camp, now completely destroyed, where arrows and javelin-heads have been found, with various English coins of high antiquity. Roman coins of the Lower Empire have likewise been met with in and near the town. Tetbury consists principally of four streets, crossing in the centre, and contains many good stone buildings. The governing officer is a bailiff, who is annually chosen. The population of the parish, including four hamlets, in the year 1811, was 2533, the number of houses 522. A weekly market is held on Wednesday, and four fairs annually. The wool-combing and wool-stapling branches are carried on here, but to no great extent. The clothing manufacture was formerly attempted, but the want of a continual supply of water prevented its being brought to perfection. Even for domestic uses, water has, till within a few years, been scarce; but in 1749, a well was sunk to the depth of 104 feet, since which time other wells have been opened, and the inconvenience in a great degree removed. The parish church consists of an ancient tower, and a modern body; the former is terminated by a spire, the latter is built in imitation of the pointed style, appearing externally as a single nave with cloisters, but within divided into aisles, by a very slight arcade and clustered columns, on the principle on which the roof of the theatre at Oxford was constructed. The old church, which was built soon after the Conquest, having become from length of time very ruinous, was taken down (excepting the tower and spire), and rebuilt at the expence of 5000l.; and opened for divine service in 1784. Two turnpike roads lead through the town in cross directions; one to London and Bath, the other to Gloucester and Southampton. A deep hollow, in the nature of a moat, at the west end, made the entrance into the town inconvenient, till the commissioners of the roads built a high bridge of four arches across it in 1775. Rudge's History of Gloucestershire, vol. i. 1803. Beauties of England and Wales, vol. v. Gloucestershire; by J. Britton and E. W. Brayley, 1803.

TETCHA, a small river of Russia, which runs into the Iset, near Dolmatov, in the province of Ekaterinburg.

TE-TCHUEN, a town of Corea; 60 miles E.N.E. of Han-tcheou.

TETE, a fort belonging to the Portuguese, in the country of Mocaranga, on the Zambeze.

TETE de Buch, La, a town of France, in the department of the Gironde, situated on the S. side of a large bay, called "The Harbour of Arcachon," the entrance of which is dangerous on account of the sand-banks; 30 miles S.W. of Bourdeaux.

TETEROA, a harbour on the W. coast of the island of Ulitea.

TETEROW, a town of the duchy of Mecklenburg; 18 miles S.W. of Gustro.

TETERSKOL, a town of Russia, on the Podkamenfskaia Tunguska. N. lat. 59° 54'. E. long 101° 14'.

TETHALASSOMENOS, a term used by the old medical writers, to express wine mixed with sea-water.

TETHER. See **TEDDER**.

TETHERING, the practice of confining animals to a certain range of feeding, by means of ropes, chains, or other contrivances.

TETHRONIUM, in *Ancient Geography*, a town of Greece, in the Phocide; being one of those which Herodotus refers to the vicinity of the river Cephissus.

TETHUROA, in *Geography*, a small island in the South Pacific ocean, subject to Otahcite, composed of six or seven low islets near each other, not many feet above the level of the sea; abounding in cocoa-nut trees, but not in bread-fruit, which the inhabitants are not allowed to cultivate. The inhabitants are about 3000, chiefly employed in catching of fish, which they bring to Otahcite, and exchange for bread-fruit; 24 miles N.W. of Point Venus. S. lat. 17° 4'. W. long. 149° 30'.

TETHYS, in *Mythology*, the daughter of Cœlum and Terra, and wife of Oceanus. Her chariot, which is represented as gliding over the surface of the waters, was a shell of an extraordinary figure, and whiter than ivory.

TETHYS, in *Zoology*, a genus of the Mollusca order of Vermes, or worms; the characters of which are, that the body is free, somewhat oblong, fleshy, and having no peduncles; the mouth terminating in a cylindric proboscis, under the lip; and two foramina on the left side of the neck. It has two species.

LEPORIUS. With a ciliated lip; found in the Mediterranean sea.

FIMBRICA. With a crenulated lip; found in the Adriatic sea.

TETIMIXIRA, in *Ichthyology*, the name of an American fish, more usually known by the name of the *pujiano*.

TETIN, in *Geography*, a town of Bohemia, in the circle of Beraun; 3 miles S. of Beraun.

TETITLAN, a town of Mexico, in the province of Xalisco; 18 miles S.E. of Compostello.

TETIUS, in *Ancient Geography*, a river of the isle of Cyprus, which ran from the N.W. to the S.E. and discharged itself into the sea, near the promontory of Dades, after having watered Citium.

TETIUSCHI, in *Geography*, a town of Russia, in the government of Kazan, on the Volga; 52 miles S. of Kazan.

TETOBE, a town of the state of Georgia; 5 miles W. of Tugeloo.

TETRACERA, in *Botany*, received that name from Linnæus, in allusion to the four horn-like points of the capsules of the original species, the word being compounded of τετρα, *four-fold*, and κέρα, *a horn*. The genus however has subsequently received an accession of several species with solitary capsules and styles, which invalidate the strict propriety of its name, and render its situation in the artificial system of Linnæus ambiguous.—Linn. Gen. 275. Schreb. 369. Willd. Sp. Pl. v. 2. 1240. Mart. Mill. Dict. v. 4. Juss. 339. Lamarek Illustr. t. 485. Gært. t. 69. (Delima; Linn. Gen.

TETRACERA.

Gen. 271. Schreb. 359. Juss. 339. Lamarck Illustr. t. 475. Gært. t. 106. Rhinium; Schreb. 701. Tigarea; Aubl. Guian. 917. Juss. 339. Lamarck Illustr. t. 826. Euryandra; Forst. Gen. t. 41. Schreb. 367. Juss. 280. See EURYANDRA.)—Class and order, *Polyandria Tetragynia*, Linn. Willd. Rather *Icosandria Monogynia*; or *Pentagynia*, according to the principles laid down in Sm. *Introd. to Bot.* ed. 3. 325. Nat. Ord. *Seneciofa*, Linn. *Rosacea*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five or six deep, rounded, unequal segments, permanent. *Cor.* Petals from three to five, roundish, concave, inserted into the calyx, and longer than its segments. *Stam.* Filaments numerous, inserted into the calyx, shorter than the petals; anthers of two round lobes. *Pistil.* Germens superior, from one to three or four, ovate, quite distinct; styles vertical, awl-shaped; stigmas obtuse. *Peric.* Capsules from one to three or four, ovate, divaricated, each of one valve, bursting along the upper edge, of one cell. *Seeds* solitary, roundish, attached to the bottom of the capsule, and clothed with a jagged tunic from the base.

Ess. Ch. Calyx in five or six deep unequal segments. Petals four or five. Capsules bursting at their upper edge. Seeds solitary, tunicated.

Obs. The capsules resemble follicles, but the seed is attached to their base.

Section I. *Flowers with a solitary germen and style.*

1. *T. farmentosa*. Trailing Tetracera. "Vahl Symb. v. 3. 70." Willd. n. 1. (*Delima farmentosa*; Linn. Sp. Pl. 736. Burm. Ind. 122. t. 37. f. 1. Piripu; Rheede Hort. Malab. v. 7. 101. t. 54. *Frutex indicus farmentosus, foliis hispida rigidis, &c.*; Burm. Zeyl. 101.)—Leaves elliptic-oblong, ferrated, rough. Style solitary. Follicle ovate, polished, brittle.—Native of Ceylon.—The stem is shrubby, with trailing, round, leafy branches, rough with minute bristly hairs. *Leaves* alternate, stalked, very rough on the upper side with minute scales, furnished with one rib, and many straight, parallel, transverse, oblique veins, which latter are hairy beneath. *Panicles* terminal, compound, many-flowered, hairy. *Calyx* of the fruit reflexed, reddish, fringed. *Follicle* pointed, the size of a small pea, brown, highly polished, clothed with erect bristly hairs. *Seed* black, standing on a toothed cup-like tunic.

2. *T. tomentosa*. Downy Tetracera. Willd. n. 2. (*Tigarea dentata*; Aubl. Guian. 920. t. 351.)—Leaves elliptical, pointed, with tooth-like ferratures; smooth above; downy beneath. Flowers dioecious. Style solitary.—Native of woods in Cayenne, flowering in January, and ripening its seed in March. The trailing shrubby branched stem climbs to the tops of the highest trees, from whence its pendulous branches reach almost to the ground. The young shoots are downy. *Leaves* alternate, stalked, four or five inches long, and two or more in breadth; their upper surface smooth and green; the under silky and hoary. The flowers and fruit agree with the following.

3. *T. aspera*. Harsh Tetracera. Willd. n. 3. (*Tigarea aspera*; Aubl. Guian. 918. t. 350.)—Leaves roundish, somewhat undulated, rough. Flowers dioecious. Style solitary.—Frequent in the woods of Cayenne, bearing flowers and fruit in January. Aublet says it is sometimes so abundant as to render the forests impassable, from the entanglement of its stems and branches, which climb to the tops of trees, and hang from thence to the ground. Their roughness, like that of the leaves, renders them the more troublesome and dangerous. The French call this shrub *Liane rouge*, or red climber, from the colour of its decoction, which the natives of the country consider as a remedy for venereal disorders. The leaves are alternate,

stalked, of a broad elliptical, or roundish, figure, obtuse, slightly wavy at the margin, rough on both sides with rigid, crooked, hoary hairs. Their ribs and veins like those of the first species. The largest leaves are three inches and a half long, and three broad. *Flowers* in axillary panicles, male on one plant, female on another. *Calyx* in four or five concave, pointed segments. *Petals* four or five, white. *Stamens* numerous, short. *Anthers* yellow, their two lobes separated by a furrow. *Pistil* abortive in the male flowers, as the stamens are without anthers in the female, whose germen is roundish, with one style, and a broad blunt stigma. *Capsule* solitary, reddish, rough to the touch, containing one seed. Aublet.

4. *T. nitida*. Polished Tetracera. "Vahl Symb. v. 3. 70." Willd. n. 8.—"Leaves lanceolate-oblong, rough, entire. Style solitary."—Supposed to be a native of Trinidad. Willd.

Willdenow has four more species in this section, of which his *T. Doliolepis*, *striata*, and *Calinea*, will be found under our article *DOLIOLEPIS*; and his *T. obovata* is our *MAPPIA*.

Section 2. *Flowers with three or four germens and styles.*

5. *T. Euryandra*. New-Caledonian Tetracera. "Vahl Symb. v. 3. 71." Willd. n. 9. (*Euryandra scandens*; Forst. Prod. 41.)—Leaves oblong, obtuse, smooth, entire. Styles three.—Native of New Caledonia. Stem shrubby, climbing. *Leaves* stalked, two inches or more in length; paler beneath.

6. *T. volubilis*. Serrated Rough Tetracera. Linn. Sp. Pl. 751. Hort. Cliff. 214. Willd. n. 10. (*Arbor americana convolvulacea*, Broad leaf, *i. e.* *platyphyllos barbadosibus dicta, foliis ferratis*; Pluk. Phyt. t. 146. f. 1.)—Leaves obovate-oblong, ferrated, very harsh. Styles four. *Calyx* silky within.—Native of the West Indies. The branches are round, with a rough, dotted, membranous, deciduous bark. *Leaves* alternate, stalked, five or six inches long, and two and a half or three wide, obtuse, very rough, like a file, with minute scales, especially beneath; each lateral rib, at least in the upper half of the leaf, terminating in a sharp but shallow ferrature. *Panicles* terminal, compound, rough with starry hairs. *Calyx* harsh and hoary externally; brittle and silky within. *Capsules* unequal, ovate, tumid, beaked, brown, smooth and highly polished; rounded, not depressed or keeled, at the sides. *Seed* small, black, in a pale, finely lacinated, tunic.

7. *T. rotundifolia*. Round-leaved Tetracera.—Leaves roundish-elliptical, entire, very harsh on both sides. Styles four. *Calyx* smooth within.—Native of Guiana. We have received specimens of this new species from Mr. Rudge and Mr. Forster, under the name of *Tigarea aspera* of Aublet, our *Tetracera aspera*, see n. 3, which, unless that author has made several great mistakes, must be a very different plant. The present has always three or four styles, and as many capsules; and the leaves, though like Aublet's t. 350. in shape, are quite entire, not undulated. They are harsh on both sides, like a very fine file, as is the branch in a less degree. The panicles are terminal. The calyx has a short, inversely conical, tube, and is hoary externally, smooth and naked within. The stamens appear to be perfect in the same flower with the four pistils. Capsules three or four, oval, brown, smooth and shining; keeled and depressed at the sides, less tumid than the foregoing. *Seed* entirely enveloped in its jagged tunic.

8. *T. levis*. Smooth Tetracera. "Vahl Symb. v. 3. 71." Willd. n. 11.—"Leaves oblong, smooth, pointed, nearly entire. Flowers terminal. Capsules four."—Native of the East Indies. Stem shrubby. *Leaves* alternate, two or three inches

inches long, veiny, smooth on both sides; tapering at the base; ferrated with a few slight teeth towards the point. *Footstalks* very short. *Flower-stalks* solitary or in pairs, terminal, an inch long. *Flowers* somewhat racemose, one or two on each partial stalk. *Calyx* with six roundish segments. *Capsules* four, as long as the finger-nail, roundish, tumid, pointed, very smooth and polished. *Seed* small, black, polished, covered in its lower half with a whitish tunic, whose margin is toothed. *Vahl.*

9. *T. almifolia.* Alder-leaved Tetracera. Willd. n. 12. —“Leaves oblong, acute, nearly entire; roughish beneath. Panicle terminal.”—Native of Guinea. *Branches* woody, round, smooth. *Leaves* coriaceous, tapering at the base, rounded at the extremity, with somewhat of a point; mostly entire, but occasionally furnished with an obsolete tooth or two near the end; veiny; shining and smooth above. *Calyx* with four deep segments. *Petals* apparently five. *Filaments* a little dilated at the end, with an anther (or lobe) at each side. *Capsules* four. *Seed* black, entirely covered by its whitish tunic. *Panicle* simple. *Stalks* three-flowered. *Willd.*

Willdenow suspects the *Astu indica*, of Houttuyn's Dutch edition of the Vegetable System of Linnæus, v. 4, 40. t. 26. f. 1, may be another species of the genus before us. The same author is also inclined to refer Thunberg's WAHLBOMIA, see that article hereafter, to *Tetracera*.

TETRACHORD, TETRACHORDON, formed of τετρα, of τετρας, four times, and χορδή, a chord, or string, in the *Ancient Music*, was a series of four sounds, of which the extremes, or first and last, constituted a fourth. These extremes were fixed and immutable; the two middle sounds were changeable according to the genera, and called *mobiles*. There were three genera or ways of tuning each tetrachord; the *diatonic*, *chromatic*, and *enharmonic*. The character of the diatonic was the tone; of the chromatic, the semitone; and of the enharmonic, the quarter-tone.

A tetrachord in the diatonic genus consisted of one major semitone and two tones.

In the chromatic genus, of two semitones and a minor third.

In the enharmonic genus, of a quarter tone, a semitone, and a major third.

The general system or scale of the Greeks consisted of tetrachords repeated, as the scale of Guido does of octaves. See *GREEK Music*.

The tetrachord of Mercury contained four strings or chords, in the proportion of twelve, nine, eight, and six; so as to give the fourth, fifth, and octave of the lowest chord. This is the opinion of Boethius, and after him of Zarlino. Vide Wallis's Append. Ptolem. Harm. p. 178.

TETRACTIS, in *Natural History*, a name given by Linkius, and other authors, to a kind of star-fish, composed only of four rays, the more common kinds having five.

TETRACTYC ARITHMETIC. See *ARITHMETIC*.

TETRACTYS, in the *Ancient Geometry*. The Pythagoric tetractys is a point, a line, a surface, and a solid.

TETRADECARHOMBIS, in *Natural History*, the name of a genus of fossils, of the class of the selenitæ.

The word is derived from the Greek τετρα, four, δεκα, ten, and ρωμβος, a rhomboidal figure, and expresses a rhomboidal body consisting of fourteen planes,

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenitæ; but that in these, each of the end planes is divided into two; and there are by this means eight of these planes, instead of four. See *SELENITES*.

TETRADIAPASON, *Quadruple Diapason*, a musical chord, otherwise called a quadruple eighth, or nine-and-twentieth. See *DIAPASON*.

TETRADITÆ, TETRADITES, in *Antiquity*, a name given to several different sects of heretics, out of some particular respect they bore to the number four, called in Greek τετρα. Thus the Sabbatians were called tetraditæ, from their fasting on Easter-day, as on the fourth day, or on Wednesday.

The Manichees, and others, who admitted of a quaternity instead of a Trinity in the Godhead, or four persons in lieu of three, were also called tetraditæ.

The followers of Petrus Fullenis bore the same appellation of tetraditæ, by reason of the addition they made to the Trifagion, to countenance an error they held, that in our Saviour's passion it was not any particular person of the Godhead, e. gr. the Son that suffered, but the whole Deity.

The ancients also gave the name tetraditæ to children born under the fourth moon, and these they believed unhappy.

TETRADIUM, in *Botany*, from τετραδιον, a party of four, as a file of four soldiers, &c. alluding to the prevalence of the number four in its parts of fructification.—Lourcir. Cochinch. 91.—Class and order, *Tetrandria Tetragynia*. Nat. Ord. *Terebintaceæ*, Juss. ? or perhaps *Rutaceæ*.

Gen. Ch. *Cal.* Perianth inferior, minute, permanent, of four spreading acute leaves. *Cor.* Petals four, ovate, incurved, or nearly erect, longer than the calyx. *Stam.* Filaments four, thick, awl-shaped, hairy, equal to the corolla in length; anthers ovate, erect, of two cells. *Pist.* Germen roundish, four-lobed; style none; stigmas four, awl-shaped, erect. *Peric.* Capsules four, roundish, bursting at the top. *Seeds* solitary, roundish, polished, tunicated.

Ess. Ch. *Calyx* inferior, of four leaves. *Petals* four. *Capsules* four. *Seeds* solitary, tunicated.

1. *T. trichotomum.* Cây dâu dàu of the Cochinchinese. Native of the hills of Cochinchina. A middle-sized tree, with ascending branches. *Leaves* pinnate, with an odd one; leaflets lanceolate, smooth, entire. *Flowers* whitish, in ample, nearly terminal, three-forked clusters; or rather, as we presume, panicles.

De Theis well remarks, that this genus appears to be allied to BRUCEA: we think also it is evidently very near FAGARA (see those articles). In deference to the weighty opinion of Jussieu, we have not, without doubt, referred it to his natural order of TEREBINACEÆ; but it appears rather to belong to his imperfectly-defined one of RUTACEÆ, to both which articles we refer the reader.

Nothing is said by Loureiro respecting the qualities or uses of this tree.

TETRADRACHM, in *Ancient Coinage*, a silver coin worth four drachmas, or 3s. sterling, the drachma being valued at 9d. But if we estimate the value of the drachma at a higher rate, that of the tetradrachm will increase in due proportion. This is the largest form of Greek silver coins, excepting the tetradrachm of the Egean standard, which is worth 5s. The largest tetradrachms weighed from 430 to 440 grains. See *DRACHM* and *SHEKEL*.

TETRADYNAMIA, in *Botany*, (from τετρα, four, and δυναμις, power, indicating a superiority of four stamens over the rest,) the fifteenth class of the Linnæan artificial system, which

which is in itself, with the exception of one genus, *Cleome*, a natural class, comprehending all the cruciform flowers. Its essential character consists in having six stamens, four of which rise above the rest. This is indeed so naturally distinct a tribe of plants, that it is hard to trace any particular affinity between them and any others. The following is the character of the flowers.

Cal. Perianth oblong, of four ovate-oblong, concave, obtuse, converging leaves, projecting downwards at their base, the opposite ones most similar to each other, deciduous. The projection generally observable at the base is for the lodgment of honey, the calyx here being a nectary, so far at least as containing the honey. *Cor.* termed cruciform, of four equal petals; their claws inversely awl-shaped, or tapering downwards, flattened, erect, rather longer than the calyx; limb flat, or nearly so, the border of each petal being dilated outwards, obtuse, its sides scarcely touching its neighbour. The petals are inserted into the same circle in which the stamens are placed. *Stam.* Filaments six, awl-shaped, erect, the two opposite ones the length of the calyx, the rest rather longer, but not equal to the corolla; anthers somewhat oblong, pointed, thickest at the base, erect, their points recurved. Nectariferous glands, variously circumstanced in the different genera, are seated at the base of the stamens, especially between the shorter ones and the pistil, those stamens, to avoid pressing upon such glands, being mostly curved, by which they become shorter than the four others. *Pist.* Germen superior, daily increasing in height; style either the length of the longer stamens, or wanting; stigma obtuse. *Peric.* Pod of two valves, and frequently as many cells, bursting from the base to the summit, the partition, if present, more or less extended beyond the valves, the prominent part being the original style. *Seeds* roundish, drooping or pendulous, ranged alternately, in a double row, along the partition, in which they make slight depressions. *Receptacle* linear, furrrounding the edge of the partition, and embraced by the margins of the valves.

Linnæus observes, that all systematic botanists, even the most eminent, have unanimously considered this as a truly natural class of plants. Some of them have nevertheless admitted into it, here and there, a genus or two in opposition to nature, which fault he justly conceives himself to have avoided, except with regard to *Cleome*.

The plants of this class have universally been termed antiscorbutic. Their flavour is generally acrid, though watery. Few vegetables yield less of an essential oil; yet this substance is to be obtained from them by cohobation, or repeated distillation, and its qualities are peculiarly acrid and fetid, somewhat like volatile alkali. This oil gives the offensive scent to water in which cabbage has been boiled, and it causes these vegetables to disagree with some stomachs, though they are generally reputed wholesome.

The class in question is divided into two orders, 1. *Siliculosa*, in which the pod is roundish, and for the most part hardly longer than its style. 2. *Siliquosa*, with a very long pod, to which the scarcely perceptible style bears no proportion.

The genera of the first order are distributed into two sections, one having the pod, here termed a *silicula*, or pouch, entire, and the other furnished with a notched, or emarginate, pouch. The genera here are characterised by the different shapes of their pouch, or its valves, and the comparative length of the style.

The order of *Siliquosa* is divided into such as have a close calyx, whose leaves converge longitudinally, and such as have a gaping, or spreading calyx. The genera here are

partly defined by the form of the pod and its valves, and their mode of bursting, and partly by the situation of the nectariferous glands.

These principles of generic distinction, laid down by Linnæus, have not proved so satisfactory in practice as could have been wished, inasmuch that, not only Haller, but some less controversial botanists, have differed from the learned Swede in their ideas of several of the cruciform genera. The best attempt to reform them has lately been made by Mr. R. Brown, in the second edition of Mr. Aiton's *Hortus Kewensis*. This able observer has recurred for assistance to the cotyledons, taking into consideration their being either folded or flat, incumbent or incumbent. The latter difference we believe to have been first noticed by Gærtner, in his characters of *Erysimum*. By *incumbent* is meant that the edges of the unexpanded cotyledons are applied, in a parallel manner, to the infant radicle; and by *incumbent*, that the flat side, or back, is presented to that part. The latter is seen in *Erysimum*, and is the most unusual position. The number of seeds in each cell of the pouch is also adverted to by Mr. Brown, as well as several other incidental marks; by the assistance of all which the whole tribe appears much more satisfactorily arranged than heretofore, though we do not profess to agree, in every point, with our learned friend. His *Mathiola*, consisting of the hoary species of *Cheiranthus*, such as *incanus*, *sinuatus*, *tricuspidatus*, &c. seems less happily separated from the original genus, than his *Malcomia*, composed of *C. maritima*, *Hesperis africana*, &c. In the latter case, the simple acute stigma, incumbent cotyledons, and the habit of the plants, afford a sufficiently clear distinction. In the former, whatever difference there may be in habit, the characters seem to us not sufficiently evident or important. It is also proper to remark, that whatever assistance such a difference as that above described in the cotyledons may afford, towards forming a philosophical idea of a genus, its great obscurity renders it unfit for practical and daily use. On this subject we need not enlarge upon what Linnæus has so happily enforced, and generally practised.

TETRAEDRON, or **TETRAHEDRON**, formed of τετρα, *four*, and ἕδρα, *side*, in *Geometry*, one of the five regular or Platonic bodies of solids, comprehended under four equilateral and equal triangles.

The tetraedron may be conceived as a triangular pyramid of four equal faces. Such is that represented in *Plate XV. Geomet. fig. 4.*

It is demonstrated by mathematicians, that the square of the side of a tetraedron is to the square of the diameter of a sphere, in which it may be inscribed, in a subsesquialteral ratio: whence it follows, that the side of a tetraedron is to the diameter of a sphere it is inscribed in, as $\sqrt{2}$ to the $\sqrt{3}$: consequently they are incommensurable. See **REGULAR Body**.

TETRAETERIS, τετραετηρίς, in the *Athenian Chronology*, a cycle of four years; for which see Potter, *Archæol. Græc. lib. ii. cap. 26. tom. i. p. 459.*

TETRAGASTRIS, in *Botany*, from τετρα and γαστήρ, *the stomach or belly*, because of the four protuberant lobes of the seed-vessel.—Gærtner. v. 2. 130. t. 109. f. 5.—Class and order, as well as *Nat. Ord.* unknown.

Nothing is known of this genus but its fruit, which Gærtner obtained from the collection at the botanic garden of Amsterdam. He describes it as a depressed *berry*, of four lobes and four cells, with solitary seeds.

Its form is nearly globose, a little depressed, convex and pointed at the summit, marked with four longitudinal furrows, separating the prominent, cushion-like lobes, into
which

which it is divided below, and which form four single-seeded cells. Its diameter is above an inch. The flesh, in the old fruit at least, is thin and rather leathery. The nuts, or cells, are large, hard, undivided, gibbous at the outside, angular at the inner, moderately thick, or rather thin, whitish, not separated from each other by any intermediate pulp. *Receptacle* central, ending in the summit of the berry, producing from its upper part four short umbilical threads. *Seeds* solitary, pendulous, large, obovate, reddish-brown. *Skin* simple, thin, coriaceous. *Albumen* none. *Embryo* the shape of the seed, inverted, pale and whitish. *Cotyledons* thick, fleshy, flat on one side, convex on the other, emarginate at the insertion of the *radicle*, which is minute, seated within the notch of the cotyledons, at their upper end.

TETRAGON, τετραγωνος, formed from τετρα, *four*, and γωνια, *angle*, in *Geometry*, a quadrangle, or a figure with four angles.

Thus a square, parallelogram, rhombus, and trapezium, are tetragonal figures.

TETRAGON, in *Astrology*, denotes an aspect of two planets with regard to the earth, when they are distant from each other a fourth part of a circle, or 90°.

The tetragon is expressed by the character □.

TETRAGONIA, in *Botany*, so called by Linnæus, from τετρα and γωνια, *an angle*, alluding to the quadrangular figure of the fruit. The word is happily abbreviated from Boerhaave's *Tetragonocarpus*, which has the same meaning. —Linn. Gen. 252. Schreb. 340. Willd. Sp. Pl. v. 2. 1023. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 210. Juss. 317. Lamarck Illustr. t. 437. Gærtn. t. 127. and 179.—Class and order, *Icosandria Pentagynia*. Nat. Ord. *Succulentæ*, Linn. *Ficoideæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, in four, occasionally three or five, ovate, flat, rather deflexed, coloured, permanent; deep segments, revolute at the edges. *Cor.* none, unless the calyx be taken for such. *Stam.* Filaments twenty, capillary, shorter than the calyx, into whose base they are inserted; anthers oblong, incumbent. *Pist.* Germen inferior, roundish, with four angles; styles four, awl-shaped, recurved, the length of the stamens; stigmas downy, running along the styles. *Peric.* Drupa coriaceous, quadrangular, with four prominent longitudinal wings, or points, the opposite ones narrowest, not bursting. *Seed.* Nut solitary, bony, of two or more cells, with oblong solitary kernels.

Ess. Ch. Calyx with from three to five deep permanent segments. Petals none. Drupa inferior, angular. Nut with several cells.

Obs. Linnæus remarks that the primary flower is five-cleft, which led him to refer this genus to the order *Pentagynia*. But it only affords an instance, among many others, that his orders of *Icosandria*, like those of *Polyandria*, except *Monogynia* and *Polygynia*, are best resolved into one, they being liable to frequent uncertainty, not only in the same genus or species, but the same individual plant. See **TETRACERA**.

1. *T. fruticosa*. Shrubby Tetragonia. Linn. Sp. Pl. 687. Willd. n. 1. Ait. n. 1. (*T. foliis linearibus*; Mill. Ic. t. 263. f. 2. *Tetragonocarpus africana* fruticans, foliis longis et angustis; Commel. Hort v. 2. 205. t. 103.)—Stem shrubby, erect. Leaves linear. Fruit winged.—Native of the Cape of Good Hope. A greenhouse plant in England, ever since the time of bishop Compton, flowering in the latter part of summer, and easily propagated by cuttings, but not endowed with much beauty, or any other quality to render it popular. The stem is shrubby, bushy, with round, alternate, leafy branches. Leaves alternate, sessile, linear-oblong, obtuse, entire, revolute, downy and soft, an

inch or more in length, with axillary tufts of smaller ones. Flowers yellow, in somewhat whorled leafy clusters.

2. *T. decumbens*. Trailing Tetragonia. Ait. ed. 1. v. 2. 177. ed. 2. n. 2. Willd. n. 2. "Decand. Pl. Grasses; t. 23. (*T. foliis ovatis integerrimis, caule fruticoso decumbente*; Mill. Ic. t. 263. f. 1.)—Stem shrubby, downy, decumbent. Leaves obovate. Fruit winged.—Native of the Cape of Good Hope. A greenhouse shrub, cultivated by Miller in 1758. It differs from the former in the larger size, and broad obtuse form of its leaves, as well as in having a more glistening mealy surface, and more numerous axillary tufts of flowers. The stem is more or less decumbent, and clothed with very soft dense hairs.

3. *T. herbacea*. Herbaceous Tetragonia. Linn. Sp. Pl. 687. Willd. n. 3. Ait. n. 3. (*Tetragonocarpus africana, radice magna crassa et carnosa*; Commel. Hort. v. 2. 203. t. 102.)—Stem herbaceous, smooth, decumbent. Leaves ovate, stalked. Flowers somewhat corymbose. Fruit winged. Native of the Cape, cultivated by Miller. The root is perennial, thick, fleshy, and lobed. Herb smooth, succulent, with many decumbent, branched, annual, leafy stems, and scattered, ovate, more or less acute, entire leaves. Flowers yellow, generally five-cleft, larger, and more showy, than in the two preceding, stalked, partly axillary, partly corymbose. All our knowledge of this species is derived from Commelin's work, nor had Linnæus any specimen in his herbarium. The last-described is sometimes, in gardens, mistaken for *T. herbacea*.

4. *T. hirsuta*. Hairy Tetragonia. Linn. Suppl. 258. Willd. n. 4. Thunb. Prodr. 87.—"Herbaceous, hairy, procumbent. Leaves ovate, villous. Flowers axillary, sessile, three together."—Gathered by Thunberg, at the Cape of Good Hope.

5. *T. spicata*. Spiked Tetragonia. Linn. Suppl. 258. Willd. n. 5. Thunb. Prodr. 87.—"Herbaceous, smooth, erect. Lower leaves ovate; uppermost lanceolate. Flowers racemose."—From the same country as the last. Thunberg. We have seen no specimens of these two species. It is remarkable that the younger Linnæus defines the flowers of *T. hirsuta* sessile, whilst Thunberg calls them stalked. Possibly the latter confounded with his *hirsuta*, our *decumbens*, of which there is a specimen, apparently gathered by him, in the Linnæan collection.

6. *T. echinata*. Hedge-hog Tetragonia. Ait. ed. 1. v. 2. 177. ed. 2. n. 4. Willd. n. 6. "Decand. Pl. Grasses, t. 113."—Stem herbaceous. Leaves rhombic-ovate. Fruit prickly.—Native of the Cape, from whence Mr. Masson introduced it at Kew, in 1774. The root is annual or biennial. Stem herbaceous, divided from the base into several decumbent branches, hardly a foot long, angular, from the decurrent footstalks, which are half the length of the spreading succulent leaves, each an inch long. Flowers pendulous, on very short, axillary, solitary, thread-shaped, purple stalks clothed with crystalline globules. Calyx in three or four segments; crystalline without; greenish-yellow within. Stamens only three or four. Germen triangular, flat underneath, its angles beset with numerous conical thorns. Styles three. Nut of three cells. Willden.

7. *T. expansa*. Horned Tetragonia. Ait. ed. 1. v. 2. 178. ed. 2. n. 5. Willd. n. 7. "Decand. Pl. Grasses, t. 114." Scop. Infubr. v. 1. 32. t. 14. Thunb. Tr. of Linn. Soc. v. 2. 335. (*T. halimifolia*; Forst. Prodr. 39. Pl. Escul. 67. *T. japonica*; Thunb. Jap. 208.)—Stem herbaceous. Leaves ovate-rhomboid; tapering at the base. Fruit with four horns.—Native of New Zealand, about the borders of woods, in bushy sandy places, as well as of the Friendly islands, and of Japan. Sir Joseph Banks introduced

it to Kew garden, in 1772, and from thence the other gardens of Europe have been supplied. The plant is a rather tender biennial herb, flowering in August and September. Forster tells us it proved a most valuable resource to captain Cook's crew, as a pot-herb, while his ship lay at Tongatabu. The whole plant is succulent, covered with very minute crystalline dots, as if moist with dew. *Root* fibrous. *Stem* divided from the bottom into many irregular, round, leafy branches. *Leaves* alternate, stalked, somewhat deltoid, entire, rather heart-shaped at the base, but tapering down into the footstalk. *Flowers* yellow, axillary, on short, usually solitary, stalks. *Fruit* turbinate, clumsy, the size of a filberd, with four or five sharp horns. The cells are five or six, answering to the number of styles.

8. *T. crystallina*. Diamond Tetragonia. Ait. ed. 1. v. 2. 178. ed. 2. n. 6. Willd. n. 8. L'Herit. Stirp. v. 1. 81. t. 39. "Decand. Pl. Grasses, t. 34."—Stem herbaceous. Leaves ovate, sessile, dotted with crystalline points. Fruit without thorns.—Native of Peru. *Dombe*. Sent to Kew, by M. Thouin, in 1788. It is annual, and flowers in the dry stove in June. *Herb* a span high, covered with crystalline granules, like the Ice-plant. *Stem* nearly erect, branched from the bottom. *Leaves* acute, entire, about two inches long, bright green. *Flowers* of a dull orange, or tawny yellow, axillary, stalked, mostly solitary. *Calyx* in four segments. *Stamens* about sixteen. *Styles* four. *Drupe* turbinate, quadrangular. *Nut* four-lobed, with four cells.

For *Tetragonia ivafolia*, Linn. Suppl. 257, see HALORAGIS, n. 1.

TETRAGONIA, in *Gardening*, contains plants of the shrubby and herbaceous, succulent, perennial kinds, among which the species most usually cultivated are the following; the shrubby tetragonia (*T. fruticosa*); the trailing tetragonia (*T. decumbens*); the herbaceous tetragonia (*T. herbacea*); and the hedge-hog tetragonia (*T. echinata*). All these plants are natives of the Cape, and, of course, of the rather tender kind.

Method of Culture.—The first and last sorts may be increased by cuttings, which should be cut off from the plants a few days before they are planted, that the part where they are cut may be healed, setting them out in July, that they may have time to make good roots before winter, on a bed of fresh earth, shading them from the sun in the heat of the day. They should afterwards be frequently refreshed with water in small quantities. In a few weeks, when well rooted, they should be taken up, and planted into pots filled with light fresh undunged earth, and be placed in a shady situation until they have taken new root, after which they may be placed with other hardy exotic plants in a sheltered situation, where they may remain till the middle or latter end of October, at which time they should be removed into the greenhouse, and placed where they may enjoy as much air as possible in mild weather, as they only require to be protected from the frost, being pretty hardy with respect to cold. As, when planted in the full ground in the summer season, they are apt to grow rank and large, or even when permitted to root into the ground through the holes at the bottom of the pots, the pots should be frequently removed to prevent it, as they are injured by it.

The first and second sorts are likewise capable of being raised by seeds, sown in a gentle hot-bed, or in a warm border of light fresh earth, in the spring. When the plants are about four inches high, they may be planted out in pots, treating them in the same manner as the cuttings.

And the third sort will grow from cuttings planted early in the spring, in the same manner as the others.

The shrubby sorts are durable in their stems, roots, and

branches; but the herbaceous kinds often die down in the stalks and branches towards the autumn, and send up new ones at the end of that season, which retain their leaves during the winter months.

They afford ornament among other potted plants, and the first sort has something singular and curious about it.

TETRAGONIAS, a name given to a meteor whose head is of a quadrangular figure, and its tail or train long, thick, and uniform: this is not much different from the trabs or beam.

TETRAGONIS, in *Ancient Geography*, a town of Arafhosa, at the foot of mount Caucasus, called more anciently Cartana. Pliny.

TETRAGONISM, τετραγωνισμος, a term which some authors use to express the quadrature of the circle.

TETRAGONOPTERUS, in *Ichthyology*. See SALMO Bimaculatus.

TETRAGONOPTRUS. See ZEUS, CHLETODON Cornutus, Nigricans, and Capistratus.

TETRAGONOTHECA, in *Botany*, from τετραγωνος, quadrangular, and θηκη, a case, or cell, a name first contrived by Dillenius, to express the square form of the common calyx, and now retained by L'Heritier and Willdenow for the original and only remaining species of the genus. See the others under DIDELTA, POLYMNIA, and WEDELIA.—Dill. Elth. 378. Linn. Gen. 438. L'Herit. Stirp. 177. Willd. Sp. Pl. v. 3. 2116. Ait. Hort. Kew. v. 5. 84. Pursh 563.—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ oppositifoliae*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Common Calyx* simple, large, of one leaf, in four deep, flat, spreading, triangular-heart-shaped segments, permanent. *Cor.* compound, radiant. Florets of the disk perfect, numerous, funnel-shaped, five-cleft, reflexed; those of the radius ten or twelve, ligulate, dilated outwards, three-cleft, equal, bluntish. *Stam.* in the florets of the disk. Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in all the florets. Germs roundish; style thread-shaped, the length of the stamens; stigmas two, reflexed or revolute. *Peric.* none. *Seeds* solitary; in the disk roundish; in the radius somewhat ovate. Down none. *Recept.* chaffy.

Eff. Ch. Receptacle chaffy. Seed-down none. Calyx simple, of one leaf, quadrangular, in four deep segments.

Obs. The synonym of *Tetragonotheca*, Linn. Gen. 438, should be erased from our article POLYMNIA.

1. *T. helianthoides*. Sun-flower Tetragonotheca. Linn. Sp. Pl. 1273. Willd. n. 1. Ait. n. 1. Pursh n. 1. (*T. doronici maximi folio*; Dill. Elth. 378. t. 283. *Polymnia tetragonotheca*; Linn. Syst. Veg. ed. 13. 658. Sm. Inf. of Georgia, v. 2. 137. t. 69.)—Native of North America, in a fertile soil, on the borders of woods, and along hedges, from Virginia to Florida, flowering from July to September. *Pursh*. The root is perennial, hardy in our gardens. *Stem* erect, round, leafy, hairy, branched, from four to six feet high. *Leaves* hairy, veiny, toothed or wavy; the lowermost stalked, ovate; upper sessile; opposite acute. *Flowers* from the forks and ends of the branches, stalked, large, of a golden yellow, resembling a sun-flower.

TETRAGONUS, in *Anatomy*, a muscle, called also *quadratus gene*.

TETRAGRAMMATON, τετραγραμματον, a denomination given by the Greeks to the Hebrew name of God, יהוה *Jehowah*, because in the Hebrew it consists of four letters. See ADONAI.

TETRAGYNIA, in *Botany*, from τετρα, and γυν, a female, the name of an order in several classes of the Linnæan artificial system, characterized, as the word itself imports,

by the flowers having four styles, or pistils. This order is better founded, and more invariable; in some classes than others. With the TETRANDRIA, (see that article,) it naturally corresponds, and is well exemplified in the genera *Potamogeton* and *Ruppia*. In *Oöandria*, though of rare occurrence, it is no less certain. In *Icofandria* and *Polyandria* it is very fallible, of which we have lately given examples. (See TETRACERA and TETRAGONIA; also POLYANDRIA.) The order *Tetragynia* in the classes *Pentandria* and *Dodecandria* is, however, sufficiently well-founded. In *Decandria* no example of it occurs, nor scarcely in *Hexandria*.

TETRAHIT, an old name, supposed to allude to the four-cornered stem. See GALEOPSIS.

TETRALOGIA, in the *Dramatic Poetry of the Ancients*, denoted four dramatic pieces of the same author, of which the three first were tragedies, and the last of the satyric kind. Their design was to celebrate a victory in the literary contests. *Aeschylus* and *Euripides* have written some pieces of this kind. Encycl.

TETRAMETER, in the *Ancient Poetry*, an iambic verse consisting of four feet.

The word is formed from *τέτρας*, four, and *μέτρον*, measure; *q. d.* four metres.—We meet with none of these but in the comic poets, as *Terence*, &c.

TETRANDRIA, in *Botany*, the fourth class in the Linnæan artificial system, is so called from *τέτρας*, and *ων*, a man, because it is characterized by having four stamens, in the same flower with the pistil or pistils. These are of equal length, the flower being regular, by which this class is distinguished from the 14th, whose flowers are ringent, and two of their four stamens, which stand next each other, are longer than the rest. See DIDYNAMIA.

The orders of this fourth class are three, distinguished by the number of their pistils. 1. *Monogynia*, a numerous and various order, comprising the ample tribe of *Proteaceæ*; and the intricate family of the *Stellateæ*, to which *Galium* and *Rubia* belong. The large genera of *Scabiosa* and *Plantago* likewise range under the *Tetrandria Monogynia*; the former of which exhibits a curious example of aberration in number between the *corolla* and *stamens*. Some of its species have a four-cleft *corolla*, answering in that respect to the *stamens*, whilst others have five segments in the former, though the number of the latter remains invariably but four. 2. *Digynia* is a small order, to which, amongst a few other genera, Linnæus has referred *Cuscuta*, but it rather belongs to *Pentandria Digynia*, the greater number of the species having five-cleft pentandrous flowers. This order will, however, receive a very curious accession in TETRARHENA. (See that article.) 3. *Tetragynia* contains *Ilex*, *Potamogeton*, and *Ruppia*, British genera, all of which have four sessile stigmas; with several others, not naturally related, but for the most part separated, by the artificial character of *number*, from their allies in other parts of the system. That character however is sufficiently constant in the present instance.

TETRANDRIA is likewise the denomination of several orders in the Linnæan System, as in *Gynandria*, if STYLIDIUM (see that article) be judged to have four stamens; and certainly in *Monoecia* and *Diœcia*, where there are several really tetrandrous genera.

TETRANGURIA, a name used by some authors for the citrul, a plant of the gourd kind, whose seeds are used in medicine.

TETRANTHERA, so named by *Jacquin*, from *τέτρας*, and *ανθηρα*, because of the four separate cells, which have the appearance of four distinct anthers, on the dilated summit of each filament, and were indeed considered as such by the

author. We greatly prefer this name to that of *Litsea*, used by *Lamarck* and *Jussieu*; because the latter is of barbarous origin, and because we are happy to follow the example of *Mr. Brown*, who justly prefers, in this case, the classical authority of *Jacquin*. To the learned *Jussieu* nevertheless belongs the honour of having first assembled under this genus several plants, which authors had either considered as distinct genera, or erroneously referred to others already established, as will appear by the various synonyms we are about to exhibit.—*Jacq. Hort. Schoenbr. v. 1. 59. Dryandr. in Roxb. Coromand. v. 2. 25. Brown Prodr. Nov. Holl. v. 1. 408. (Litsea; Lamarck Dict. v. 3. 574. Juss. in Bull. des Sciences, v. 3. 73. Tomex; Thunb. Jap. 10. Nov. Gen. 65. Schreb. Gen. 315. Willd. Sp. Pl. v. 2. 839. Mart. Mill. Dict. v. 4. Juss. 440. Hexanthus; Loureir. Cochinch. 195. Sebifera; Loureir. ibid. 637. See TOMEX, HEXANTHUS, and SEBIFERA.)—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Lauri*, Juss. *Laurineæ*, *Brown*.*

Gen. Ch. *Cal.* Involucrum of four or five ovate, concave, deciduous leaves, containing several stalked flowers. Perianth none, unless the corolla be taken for such. *Cor.* of one petal, tubular, more or less deeply divided into from four to six elliptic-oblong equal segments; sometimes abrupt and entire, the limb being deficient. Nectary of several stalked glands or scales intermixed with the stamens. *Stam.* Filaments from twelve to eighteen, sometimes but six, thread-shaped, erect, the outer ones longest; anthers with four lateral cells at their inner side. *Pistl.* Germen superior, ovate; style thread-shaped; stigma notched. *Peric.* Berry ovate or globose, of one cell. *Seed* solitary, the shape of the berry.

Obs. The stamens are usually imperfect in the flowers of one tree, and the pistil in those of another; but this is hardly a sufficient reason for placing this genus in the class *Diœcia*, the structure of the flowers being alike, and both organs, at least their rudiments, present in each. The four cells of the anthers, as *Mr. Brown* observes, distinguish *Tetranthera* from *Laurus*.

Ess. Ch. Involucrum of four or five leaves, deciduous. Corolla with about five segments. Nectary of several stalked glands. Anthers of four lateral cells. Stigma somewhat lobed. Berry superior, with one seed.

1. *T. japonica*. Japan *Tetranthera*. (*Tomex japonica*; Willd. n. 1. Thunb. Jap. 190.)—Stamens twelve. Leaves obtuse; downy beneath, as well as the involucrum. Flower-stalks simple.—Common at *Kosido* in Japan, flowering in October and November.—It is there known by the name of *Fiswa*. The stem is arboreous, tall, branching, above two feet in diameter. Branches downy, knotty; angular when young. Leaves alternate, stalked, oblong, obtuse, entire, erect, with parallel ribs; smooth and green above; hoary and downy beneath; three or four inches long. Footstalks angular, striated, downy, an inch in length. Flowers axillary, capitate, dioecious, on solitary, angular, downy, bracteated stalks, half an inch long. The involucrum consists of five or six leaves, the outer ones smallest, and contains the same number of flowers. *Thunberg*.

2. *T. laurifolia*. Laurel-leaved *Tetranthera*. *Jacq. Hort. Schoenbr. v. 1. 59. t. 113. (Tomex Tetranthera; Willd. n. 2.)*—Stamens about fifteen. Leaves obtuse, smooth, as well as the involucrum. Flower-stalks somewhat umbellate.—Native of China. Cultivated at the *Mauritius* by the name of *Cerisier de la Chine*, or Chinese Cherry-tree. From thence it was brought to *Schoenbrun* gardens, where it bears the open air in summer, and flowers in the hot-house in September and October.—It is there a tree, ten feet

feet high, with a head of round knotty *branches*, downy when young. *Leaves* about the ends of the branches, alternate, on downy stalks, an inch long, obovate, coriaceous, entire, light green, smooth and shining, except a slight pubescence on the rib and veins; their length about five inches. *Flower-stalks* lateral, scattered, below the leaves, umbellate, about two inches long, each bearing from two to five *flowers*, whose *involucrum* is pale green, *corolla* white; their short partial stalks (within the involucre) hairy, as well as the *filaments*. *Berries* red, globose, the size of a currant. Jacquin says nothing of the dioecious nature of the *flowers*, but he appears to describe one with an imperfect *pistil*. His *fruit* perhaps was of exotic growth.

3. *T. apetala*. Apetalous Tetranthera. Roxb. Coromand. v. 2. 25. t. 147. Brown n. 1. (*Laurus involucrata*; Retz. Obs. fasc. 6. 27?)—Stamens about fifteen. Leaves elliptical, obtuse, single-ribbed, smooth. Corolla abrupt, undivided, bearing the stamens on its margin.—Native of the mountainous parts of the circars of Hindoostan, flowering in June. Roxburgh. Mr. Brown met with the same in the tropical part of New Holland. This is said to be a middle-sized *tree*, with round smooth *branches*, leafy towards the ends. The *leaves* are stalked, three or four inches long, and two, or two and a half, wide, entire, bright green. *Flower-stalks* usually three-flowered, much like those of the last, to which this species is nearly akin; but the want of a limb to the *corolla*, and the oval violet-coloured *berry*, sufficiently distinguish it.

4. *T. monopetala*. Monopetalous Tetranthera. Roxb. Corom. v. 2. 26. t. 148.—Stamens about nine. Leaves elliptic-oblong, acute, single-ribbed; somewhat downy beneath. Flowers clustered. Limb of the corolla half five-cleft.—Native of the vallies of Hindoostan; flowering in the hot season. Dr. Roxburgh says the *wood* is white, tolerably hard; and that the bark is used by the inhabitants of the hills, to cure diarrhœas, being given in substance. Its taste is mildly astringent; with much balsamic sweetness. The *leaves* are longer, narrower, and more acute than in the former. *Flowers* in short, axillary, dense, partly umbellate, clusters, with five leaves to the *involucrum*, and as many segments to the greenish tubular *corolla*. *Berries* ovate, of a violet black.

5. *T. ferruginea*. Rusty Tetranthera. Brown n. 2. (*Hexanthus umbellatus*; Loureir. Cochinch. 196. *Litsea hexantha*; Juss. n. 4.)—Stamens about nine. Leaves elliptic-oblong, acute, single-ribbed; downy beneath, as well as the branches. Corolla in six deep segments.—Native of Cochinchina, as well as of the tropical part of New Holland. A *tree* of a moderate size, whose timber is used in building. The *leaves* are large, entire, with many transverse veins. *Flowers* pale green, in small axillary umbels.

6. *T. dealbata*. White-leaved Tetranthera. Brown n. 3.—Stamens six. Leaves broadly elliptical, pointed, triple-ribbed, smooth; whitened beneath. Footstalks and branches downy. Corolla deeply four-cleft, hairy. *Involucrum* villous.—Native of the neighbourhood of Port Jackson, New South Wales. Mr. Brown thinks *Laurus Myrrha*, Loureir. Cochinch. 251, which is perhaps not specifically different from *Laurus involucrata*, Roxb. Coromand. v. 2. 46. t. 187, is very nearly related to the present species, though differing in having smaller *leaves*, a somewhat silky *involucrum* on a short stalk, and nearly smooth *corolla*. We cannot but observe that Roxburgh's t. 187. by no means exhibits the peculiar *anthers* or *nectary* of a *Tetranthera*. His plant however should seem to be the *Litsea trinervia* of Jussieu, which the latter takes for *Laurus*

involucrata of Retzius, but that should have single-ribbed *leaves*. See our third species.

7. *T. chinensis*. Chinese Tetranthera. (*Litsea chinensis*; Lamarck Dict. v. 3. 574. Juss. n. 5.)—Stamens numerous, polyadelphous. Leaves elliptical, obtuse, smooth. Footstalks, branches, and involucre downy. Corolla none.—Native of China; cultivated in the island of Mauritius, where its power of resisting the force of high winds, renders this tree valuable for making tall hedges. The *leaves* are four inches long, two broad; pale beneath. *Flowers* dioecious. *Involucrum* of four concave, spreading, downy leaves. *Stamens* united into from five to nine downy bundles. *Germen* surrounded with abortive stamens. *Berry* spherical, smooth, the size of a small cherry, with a flavour of camphor and ivy, which renders it disagreeable, and only fit food for birds. Lamarck. This species is said to have been brought alive to Europe, and was in 1789 cultivated in the Parisian garden; but we have neither heard nor seen any thing of it in England.

8. *T. sebifera*. Tallow Tetranthera. (*Tomex sebifera*; Willd. n. 3, excluding the synonym of Retzius. *Sebifera glutinosa*; Loureir. Cochinch. 638.)—Stamens from twelve to fifteen. Leaves ovate-oblong, bluntish, single-ribbed, smooth. Flower-stalks umbellate, downy as well as the involucre. Corolla none.—For a further account of this species, see SEBIFERA, under which article Loureiro's faulty generic character, and especially his description of the stamens, prevented our recognizing the plant as already described by Willdenow.

9. *T. piperita*. Pepper Tetranthera. (*Litsea piperita*; Juss. n. 7. *Laurus Cubeba*; Loureir. Cochinch. 252.)—Stamens six. Leaves lanceolate, without rib or vein. Stalks single-flowered. Corolla in six roundish unequal segments.—Native of Cochinchina, and perhaps also of China. In the former country it is frequently cultivated, for the sake of the cordial and tonic qualities of its berries and bark. A decoction of one or the other, the latter being weakest, is given in hysteric, paralytic, and melancholic disorders. The recent fruit is used as a seasoning for fish. The scent is fragrant; taste aromatic and pungent. Each berry resembles a grain of black pepper, with a long slender stalk. Loureiro suspected it to be the true *Cubeba*, but erroneously. (See PIPER.) The *tree* is of a moderate size, much branched. *Leaves* alternate, stalked, two inches long, entire, flat, shining, and, we presume, smooth. *Flowers* white, on crowded, lateral, simple stalks. *Involucrum* of four roundish, concave, coloured, deciduous leaves, containing five flowers. *Style* none. *Berry* globose, very small, black.—Such is Loureiro's account, from which, having seen no specimen, we have extracted the specific character.

TETRANTHUS, so called by professor Swartz, in his *Prodromus*, p. 115, from *τετρα* and *ανθος*, on account of the four flowers in one common calyx.—Schreb. Gen. 592. Willd. Sp. Pl. v. 3. 2402. Mart. Mill. Dict. v. 4. Swartz Ind. Occ. 1385. t. 27.—Class and order, *Syngenesia Polygamia-segregata*. Nat. Ord. *Compositæ capitata*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* of five small, linear, fringed leaves, at first reflexed, then erect, containing four flowers: *partial* of one leaf, tubular, much longer than the former; tapering and somewhat compressed at the base; oblique, acute and fringed at the summit; containing one floret. *Cor.* of each floret tubular; its limb in five unequal segments, the three lowermost longest, and most reflexed. *Stam.* in each floret, Filaments five, capillary; anthers united into a cylindrical tube, rather shorter than the tube of the corolla. *Pist.* *Germen* superior, in the tube of the partial calyx, oblong; style thread-

thread-shaped, divided, spreading, longer than the corolla; stigmas linear, downy, reflexed. *Peric.* none, except the permanent sheathing partial calyx. *Seeds* solitary, oblong, somewhat striated, crowned with a membranous fringed border. *Recept.* minute, naked.

Eff. Ch. Common Calyx of five leaves, containing four flowers: partial of one oblique leaf. Seeds with a membranous fringed border. *Receptacle* naked.

1. *T. littoralis.* Shore Tetranthus. Willd. n. 1. Swartz Ind. Occ. 1386.—Found on the banks of rivers in Hispaniola. A small annual herb, flowering in the spring, and, as Swartz justly observes, very peculiar in its fructification. There certainly cannot be a better example of the order *Polygamia-segregata*. Willdenow says it has the aspect of MITCHELLIA; see that article. The *stem* is slender, creeping, smooth, subdivided, a span long, attaching itself by little tufts of long white fibrous *radicles* from each joint. *Leaves* opposite, stalked, roundish-ovate, entire, with a short obtuse point, three-ribbed, smooth, half an inch long. *Footstalks* smooth and slender, nearly an inch in length. *Flower-stalks* axillary, solitary, erect, longer than the leaves, slender and downy. *Flowers* small, white.

TETRAO, in *Ornithology*, a genus of the Gallinæ order of birds; the characters of which are, that it has a spot near the eyes naked, or papillose, or rarely covered with feathers. It comprehends sixty-seven species, classed under several divisions and subdivisions.

A. *With the naked Spot above the Eyes, and hairy Legs.*
LAGOPODES.

a. *With four-toed Feet.*

UROGALLUS. With roundish tail, and white axillæ. This is the cock of the wood of Ray and Willughby, and wood grouse of Pennant and Latham. (See GROUSE.) It is found in the forests and marshes of the colder parts of Europe and Northern Asia.

PHASIANELLUS. With wedge-shaped tail; head, neck, and body above, testaceous, and black-banded. This is the long-tailed grouse from Hudson's Bay of Edwards, long-tailed grouse of Latham, and sharp-tailed grouse of Pennant. Found in Hudson's Bay and the uncultivated parts of Virginia.

TETRIX. With bifurcated tail, secondary quills white towards the base. This is the urogallus minor of Brisson and Gesner, and black cock, black game, or black grouse of Ray, Willughby, Pennant, and Latham. Found in the woods, heaths, &c. of the cold parts of Europe and Siberia. (See GROUSE.) The varieties of this species are the tetrix alba of Blum. Act. Stock. 1785, and the urogallus minor punctatus of Brisson, or tetrao hybridus of Sparrman, or spurious grouse of Pennant.

NEMESIANUS. With red tail, spotted with black; black tip, and body varied with black and red: the Nemesian grouse of Latham.

BETULINUS. With black tail, varied with black transverse spots; and rump whitish, with black bands: the birch grouse of Latham.

CANADENSIS. With black tail-feathers, yellow at the tip, and two white streaks at the eyes: the black and spotted heath-cock of Edwards, and spotted grouse of Pennant, Forster, and Latham; and gelinotte du Canada of Buffon.

CANACE. With entire tail, and white spot near the ears and nostrils: the black and spotted heath-cock of Edwards. Found at Hudson's Bay.

LAGOPUS. Cinereous; hairy toes; white quills; black tail-feathers, tipped with white; the intermediate white:

this is the white game of Willughby, and ptarmigan of Pennant and Latham. (See PTARMIGAN.) Of this species there are several varieties; as the lagopus varia of Gesner and Willughby, the bonasia scotica of Brisson, and the attingen of Brisson, or red game, moor-cock, or gor-cock of Ray and Willughby, and red grouse of Pennant and Latham. (See GOR-COCK.) Found in Siberia and the northern parts of Europe.

ALBUS. Orange, varied with black bands and white streaks; hairy toes; tail-feathers black, tipped with white; the intermediate wholly white: this is the white partridge of Ellis and Edwards, and the white grouse of Pennant and Latham. Found gregarious in the forests of North America, Europe, and Asia.

RUPESTRIS. Orange, varied with black bands and white streaks; plumose toes; black tail-feathers tipped with white; the intermediate wholly white with black lores: this is the rock grouse of Pennant. Found at Hudson's Bay.

LAPPONICUS. With naked scaly legs; with a superciliary scarlet line covered with a membrane of the same colour; the primary quill-feathers and tail-feathers tipped with white: the rehufak of the Arctic Zoology. Found in the woods and mountains of Lapland.

CUPIDO. With succenturiate cervical wings: the attinga americana of Brisson, and pinnated grouse of the Arctic Zoology and of Latham. Found gregarious in North America.

UMBELLUS. With the cervical umbo exstant: this is the attinga pennsylvanica of Brisson, the ruffed heath-cock of Edwards, and ruffed grouse of the Arctic Zoology and of Latham. Found in North America.

TOGATUS. With the greater axillary feathers black-azure: this is the bonasia major canadensis of Brisson, and shoulder-knot grouse of Forster (Phil. Transf. vol. lxii.) and of Latham. Found at Hudson's Bay.

BONASIA. The tail-feathers cinereous, with black points and band; the two intermediate excepted: this is the bonasia of Brisson, the gallina corylorum of Gesner and Aldrovand, the gelinotte of Buffon, the hafelhuhn of Ray and Willughby, and hazel grouse of the Arctic Zoology and of Latham. Found among the hazels of Europe and Western Siberia.

CANUS. Body grey, undulated with brown; the beak and legs black. Found in Sweden.

ALCATA. Above varied; the two intermediate tail-feathers twice longer than the others, and subulate: the ganga of Buffon, the partridge of Damascus of Willughby and Ray, the kitiwiah or African lagopus of Shaw's Travels, the kara of Ruffel's Aleppo, the little pin-tailed grouse of Edwards and Latham. Of this there are two varieties, viz. the tetrao senegallus and gelinotte of Senegal of Buffon; and the tetrao caudatus of Gmelin's Travels. Found in Southern Europe, Africa, Arabia, Syria, and Persia.

NAMAQUA. Above spadiceous, with the two intermediate tail-feathers longer and subulate: the Namaqua grouse of Latham. Found in Africa amid the dry deserts inhabited by the Namaquis, flying gregarious to fountains.

INDICUS. Front white, surrounded by a wreath behind black; the body above yellowish-red, varied with black lunules: the Indian grouse of Latham. Found at Coromandel.

ARENARIUS. Ruff, abdomen, and vent black; tail-feathers with brown and grey bands, tipped white; the two intermediate yellowish: the sand grouse of Latham. Found about the Volga near Astrachan.

b. *With three-toed Feet.*

PARADOXUS. With three-toed feet; toes hairy, almost joined

TETRAO.

joined at the apex: this is the heteroclitous grouse of Latham. Found in the Southern Tartarian desert.

B. With papillose Skin about the Eyes; and naked Legs.

c. With the Feet of the Male Spurred. PERDICES, or Partridges.

FRANCOLINUS. Abdomen and throat black, and wedge-formed tail: this is the tetrao orientalis of Haffelquist, and francolin of other authors. Found in the south of Asia and Europe, and in Africa, of the size of the partridge, feeding on seeds, emitting a hissing sound, and flesh delicious.

MADAGASCARIENSIS. Abdomen black, varied with large red spots; throat white; the two intermediate tail-feathers reddish, with black bands; the pintado partridge of Latham. Found in Madagascar.

RUFUS. Legs and beak fanguineous; throat white, surrounded with a band black, white pointed: this is the perdx græca of Brisson and Ray, the bartavelle of Buffon, the red partridge of Albin, the Greek or great red partridge of Willughby, and Greek partridge of Latham. Of this species there are three varieties, viz. the tetrao rufus of Gmelin, or perdx rubra of Brisson, or perdx rufa major of Gefner and Jonston, or red-legged partridge of Ray, Willughby, and Albin, or Guernley partridge of Latham; the perdx rufa alba of Brisson; and the perdx rubra barbarica of Brisson, or the red-legged partridge from Barbary of Edwards, or Barbary partridge of Shaw's Travels. Found gregarious in the woody mountains of Europe, Asia, and Africa, much larger than the partridge.

PERDIX. With a naked scarlet spot under the eyes; tail ferruginous; breast brown; and legs whitish: this is the common partridge, (which see.) Of this species there are the following varieties; viz. perdx cinereo alba of Brisson; perdx tota alba; perdx torque albo; perdx brunnea; perdx mento gulaque, or chin and throat red. Found in flocks in the cultivated fields and pastures of Europe and Siberia.

DAMASCENUS. With a naked scarlet spot under the eyes; tail ferruginous; breast brown; and legs yellow: the perdx damascena of Brisson, and Damascus partridge of Ray, Willughby, and Latham. This species migrates in flocks through the middle of Europe, and is allied to the partridge, but less, with a longer beak.

MONTANUS. Legs and beak red; throat reddish and dingy: the perdx montana of Brisson. Found in the mountains of Europe.

RUBRICOLLIS. Legs, beak, chin, and throat naked, all red: the red-necked partridge of Latham. Found in Africa.

PETROSUS. Beak and legs red; body brown, and ferruginous spot on the breast: the rufous-breasted partridge of Latham. Found amid the rocks and mountains near Gambia.

PERLATUS. Legs and eye-brows red; beak blackish; throat white; and body varied with brown: the perdx chinensis of Brisson, and pearly partridge of Latham. Found in China: and it has a variety with beak and legs brown, eye-brows spotted with white and black, at the Cape of Good Hope.

BICALCARATUS. With double-spurred feet, and black eye-brows: the Senegal partridge of Latham. Found near the Senegal.

ZEYLONENSIS. With double-spurred feet; beak and naked area of the eyes red; tail round and brown: the Ceylon partridge of Latham.

SPADICEUS. With two-spurred feet red; beak yellow;

and body spadiceous or bright red-coloured; the brown African partridge of Latham. Found in Madagascar.

NUDICOLLIS. With two-spurred feet, and naked throat red; the bare-necked partridge of Latham.

GINGICUS. Bill black; rump and tail red, grey, and black mixed; and eye-brows white: the Gingi partridge of Latham. Found near Gingi, in Coromandel.

PONDICERIANUS. Bill black; two intermediate tail-feathers red, numerous angulated lines brown; and four bands ochre-coloured: the Pondicherry partridge of Latham. Found in Coromandel.

NEVIUS. Legs and bill reddish; body brown, variegated with yellow: the oocolin of Ray and Buffon, the Mexican partridge of Latham. Found in the temperate parts of New Spain.

d. Coturnices, or Quails. See QUAILS.

e. With four Toes.

FERRUGINEUS. Legs and beak brown; body beneath diluted light red, above ferruginous-brown; feathers of the neck longer and acutely tipped; the hackled partridge of Latham. Found in China.

JAVANICUS. Legs flesh-coloured; front, spot on the hind head, and abdomen, orange; beak, breast and tail cinereous, varied with black: Javan partridge of Latham. Found in the island of Java.

VIRIDIS. Green; legs and beak reddish; area of the eyes red; wings spadiceous: the green partridge of Latham.

VIRGINIANUS. With a black band above and below the eyes; vertical line yellow; the Virginian partridge of Latham. Found among the trees of America.

MARILANDUS. With white eye-brows; neck pointed with white and black: the New England partridge of various writers; the Maryland partridge of the Arctic Zoology and of Latham. Found in America.

KAKELIK. Bill, eye-lids and legs scarlet; breast cinereous; back undulated with white and cinereous. Found in Bucharia, &c.

CASPIUS. Cinereous, spotted with light red; the nostrils, orbits, and temples dusky. Found near Astrabad, in Persia.

MEXICANUS. Legs and bill fanguineous; the superciliary line white: the coturnix ludoviciana of Brisson, colcuicuitu of Ray and Willughby, the Louisiana quail of Latham. Found in Louisiana.

FALKLANDICUS. Variegated with brown spots and curved striæ; beneath white; bill lead-coloured; legs brown; temples spotted with white: Malouine quail of Latham. Found in the Falkland islands.

NOVÆ HISPANÆ. Legs and bill black; crested head and neck variegated with white and black; body and quill-feathers yellow, the latter tipped with white: this is the grand colin of Buffon, and Mexican quail of Latham. Found in New Spain.

COYOLCOOS. With yellow legs; crown and neck fasciated with white and black; body above yellow, varied with white. This is the coturnix mexicana of Brisson; the coyolcozquo of Ray and Willughby, the coyolcos of Buffon, and lesser Mexican quail of Latham; the eyes are black.

SUSCITATOR. Variegated with yellowish, red, black and grey; bill longer. This is the coturnix javensis of Brisson, the coturnix indica Bontii of Ray and Willughby, the reveil-matin or caille de Java of Buffon, and noisy quail of Latham. Found in the woods of Java.

STRIATUS. With reddish legs; white eye-brows; tail, throat,

throat, lower breast and abdomen black, white-guttated: the Madagascar quail of Latham.

GRISEUS. With black legs and bill; body dilutely and sordidly grey, black-banded: the grey-throated quail of Latham. Found in Madagascar.

COROMANDELICUS. Head black; vertex and ocular fascia red and yellow; throat white, surrounded with a black stria; body striated; quill-feathers brown: the Coromandel quail of Latham.

NOVÆ GUINÆÆ. Brown; greyish legs; black quill-feathers, the covers of the wings obsolete yellow: the New Guinea quail of Latham.

MANILLENSIS. Above black; legs and bill black; throat white; breast grey, spotted black; abdomen yellow, black-banded: the Manilla quail of Latham.

CRISTATUS. The dependent crest and throat yellow: this is the quauhtzonecolin of Ray and Willughby, the zone-colin of Buffon, the crested quail of Latham. Found in Guiana and New Spain.

SINENSIS. Body spotted grey; throat black, with a white bow: the coturnix philippensis of Brisson, and Chinese quail of Edwards and Latham. Found in China and the Philippine Isles.

COTURNIX. Body spotted grey; eye-brows white; the margin and lunule of the tail-feathers ferruginous: the quail of Pennant and others. Of this there are two varieties, the coturnix major of Brisson, and the coturnix wholly white.

f. *With three Toes.*

GIBRALTARICUS. With pale legs; black bill; quill-feathers and tail black: the Gibraltar quail of Latham.

ANDALUSICUS. Red, variegated with black; beneath reddish-white; legs and bill flesh-coloured: the Andalusian quail of Latham.

NIGRICOLLIS. Body above cinereous, variegated with red and black beneath; legs and bill cinereous; chin and throat black; quill-feathers brown: black-necked quail of Latham. Found in Madagascar.

LUZONNIENSIS. Head, neck, and throat variegated with white and black; throat and breast bay; abdomen yellowish; legs and bill dilutely grey: the Luzonian quail of Latham. Found in the Manilla Islands.

C. *With the Area about the Eyes covered with Feathers, but naked and tetradyte:* TINAMOU.

GUIANENSIS. With legs and bill brown; back variegated with cinereous brown and blackish streaks; throat cinereous; abdomen palely orange and brown. This is the partridge of Guiana of Bancroft and Latham. Found in Cayenne and Guiana.

MAJOR. Legs yellowish and brown; bill black; vertex red; body olivaceous; spots on the back and tail black. This is the macucagua of Marcgrave, Ray, and Willughby, the magona of Buffon, the tinamou of Cayenne, the great tinamou of Latham. Found in South America, particularly in the woods of Cayenne and Guiana.

CINEREUS. Cinereous-brown: the cinereous tinamou of Latham.

VARIEGATUS. Legs and bill brown; head and neck black; body above variegated with transverse lines, light red and black; beneath red; throat and middle of the abdomen white: the variegated tinamou of Latham. Found in Guiana.

SUVI. Legs and bill yellow; head and neck black; body above brown; beneath red: the little tinamou of Latham. Found in Guiana.

TETRAODON, in *Ichthyology*. See TETRODON.

TETRAPETALOUS, in *Botany*, an epithet given to the flowers that consist of four single petals, or leaves placed around the pistil.

These M. Jussieu calls *polypetalous* flowers.

Mr. Ray, who calls them *tetrapetalous*, makes them constitute a distinct class, which he divides into, 1. Such as have an uniform tetrapetalous flower, and their seed-vessels a little oblongish, which he therefore calls *siliquose*. 2. Such as have their seed-vessels shorter, which therefore, for distinction sake, he calls *capsulate* and *siliculose*. 3. Such as have a seeming tetrapetalous flower, that is, a monopetalous one, divided deeply into four partitions, which he particularizes also as *anomalous*.

TETRAPHARMACUM, τετραφαρμακον, compounded of τετρα, *four*, and φαρμακον, *drug*, or *remedy*, in the general denotes any remedy consisting of four ingredients.

TETRAPHIS, in *Botany*, a name contrived by Hedwig, to express the four points by which the fringe of this moss is peculiarly distinguished. (See FRINGE.)—Hedw. Fund. v. 2. 87. t. 7. f. 32. Schreb. Gen. 758. Sm. Fl. Brit. 1179. Compend. 153.—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Eff. Ch. Capsule oblong. Fringe simple, of four pyramidal, erect, unconnected teeth.

1. *T. pellucida*. Transparent Four-toothed Moss. Fl. Brit. n. 1. Compend. 163. Engl. Bot. t. 1020. Hedw. Sp. Musc. 45. t. 7. f. 1. a-f. Sibth. Oxon. 275. Turn. Musc. Hib. 13. (Mnium pellucidum; Linn. Sp. Pl. 1574. M. serpilli foliis tenuibus pellucidis; Dill. Musc. 232. t. 31. f. 2.)—Capsule cylindrical. Leaves ovate, acute, single-ribbed.—Not rare in moist shady places, about the roots of trees, in various parts of Europe. It is annual, flowering early in the spring, and ripening fruit in May. The whole moss is of a bright transparent green. Root fibrous, matted. Stems mostly simple, an inch high, clothed with alternate, sessile, ovato-lanceolate, acute, entire, wavy, single-ribbed leaves, and each terminated by a solitary flower. The male flowers, far more abundant than the female, are little, round, stalked, powdery heads, each enveloped in three broad ovate leaves. The females, on a different stem, are less elevated, and more minute, each with from four to six styles, one of which only, as usual, is prolific, and the cylindrical, smooth, nearly upright capsule becomes elevated on a bright orange or crimson stalk, an inch long. The tawny veil is torn at the base. Lid conical, reddish, thin, not half so long as the capsule. Fringe remarkable for its four rigid, polished, acute, pyramidal teeth, of a shining brown, by which the genus was well characterized, even when the present was the only known species. Hedwig observed the flowers to be sometimes abortive, and replaced by buds. In the early spring he now and then met with *stamens* and *pistils* in the same flower.

2. *T. ovata*. Ovate Four-toothed Moss. Mohr Ind. Crypt. 3. Sm. Compend. 163. Grimmia Browniana; Engl. Bot. t. 1422. Bryum Brownianum; Dickf. Crypt. fasc. 4. 7. t. 10. f. 16. Orthotrichum Brownianum; Fl. Brit. 1269.)—Capsule ovate. Radical leaves ligulate, obtuse, without a rib.—Gathered by Mr. R. Brown, by the river side at Roslin, near Edinburgh; and by the late Mr. William Brunton, on sand-stone rocks at Lord Grantley's lakes, near Ripon, Yorkshire. The habit of the plant, and especially the ribbed veil, caused us first to refer our imperfect specimen to *Orthotrichum*, till Mr. Sowerby thought he found the fringe to be that of a *Grimmia*. Meanwhile Mr. Funk, a German botanist, ascertained it to be formed of four teeth only, constituting a genuine *Tetraphis*,
thus

thus adding a second species to the curious genus before us. With respect to habit, indeed, this has little resemblance to the original species. It is a minute, brownish, pellucid moss, whose foliage is all over dotted or reticulated. The root seems annual. *Stems* none. *Radical leaves* few, erect, linear, very narrow, a little dilated upwards, obtuse, entire, without rib or vein: those which form a *sheath*, at the base of the *fruitstalk*, short, ovate, acute, with a rib or keel. *Stalk* red, solitary, half an inch high. *Capsule* erect, smooth, ovate, brown. *Lid* short, with an oblique point. *Fringe* red, certainly of only four short, acute, firm teeth.

TETRAPHOE, a name given by the people of Guinea to a plant, which they give in decoction as a cure for fluxes. This plant grows also in Malabar, where they use the roots boiled in whey for the piles; and in the colic they give the root in powder, about a scruple for a dose. It is called in this latter place *wellia cadavalli*, and by Petiver *xanthium Malabaricum capitulis lanuginosis*. The stalks of it are woody and hoary, especially about the tops. Its leaves stand by pairs on short footstalks, and while young they are hoary underneath, with a very soft and velvety down; the others are rough, like the spotted lungwort, but seldom are so large; the flowers grow in spikes, and consist each of fine green leaves filled with scarlet filaments; after these the fruit ripens, and is a sort of woolly bur, covered with soft and hooked prickles, very like the common English burdock, but not of a third part of the size. Phil. Trans. N^o 232.

TETRAPILUS, a genus of Loureiro's, in his Cochinch. 611, named from τετρα, and πῖλος, a hat, or hood, because the four segments of the corolla end each in a hooded point. Every part of the description answers to the genus OLEA, see that article; except that the flowers are dioecious (which indeed is of little consequence, some of the known species being subject to have the stamens and pistils occasionally in separate flowers); and the berry is said to have two cells, with several seeds. Though *Olea* therefore is known to have two cells in the young germen, there being here more than one seed, must reduce Loureiro's plant to *Ligustrum*; and it may prove very near *L. japonicum*, Thunb. Jap. 17. t. 1, though scarcely the same species.

TETRAPLA, formed from τετραπλος, quadruplex, four-fold, in *Church History*, a Bible disposed by Origen, under four columns, in each of which was a different Greek version, viz. that of Aquila, that of Symmachus, that of the Seventy, and that of Theodotion.

Sixtus of Sienna confounds the tetrapla with the hexapla; but the tetrapla is a different work, composed after the hexapla, and in favour of such as could not have the hexapla.

Some authors are of opinion, that the order in which the four versions of the tetrapla were ranged, was different from that in which we have rehearsed them; and particularly, that the Septuagint was in the first column; but St. Epiphanius says expressly to the contrary, and places it in the third. He even gives us Origen's reason for putting it there, which was, says he, that the best version might be in the middle, that the others might be the more easily confronted with it, and corrected from it.

Baronius, however, in his Annals for the year 231, takes the Septuagint to have been in the third place in the hexapla, but in the first in the tetrapla; but Epiphanius gives it the same place in both. See HEXAPLA.

TETRAPOGON, in *Botany*, so named by Desfontaines, from τετρα, and πωγων, a beard, because of the four awns

assembled in each calyx.—Desfont. Atlant. v. 2. 388. Willd. Sp. Pl. v. 4. 898.—Class and order, *Polygamia Monœcia*, Desfont. and Willd. rather *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two nearly equal, oblong, membranous, shining, awnless valves, containing three florets. *Cor.* of two valves; the outer one keeled, abrupt, villous, with a long, straight, terminal, spreading awn; inner smaller, membranous, awnless. *Stam.* Filaments three, short, capillary, deflexed; anthers oblong, emarginate, pendulous. *Pist.* Germen small, roundish, superior; styles two, short; stigmas feathery, oblong. *Peric.* none, except the permanent corolla. *Seed* solitary, invested with the corolla, but not united to it. The terminal *floret* is imperfect, but both valves are awned.

Ess. Ch. Calyx of two valves, three-flowered. Corolla of two unequal valves; the outermost abrupt, awned. Central floret imperfect; both valves awned.

1. *T. villosus*. Villous Four-bearded Grass. Willd. n. 1. Desfont. Atlant. v. 2. 389. t. 255.—Gathered by Desfontaines in sandy ground in Barbary, near Casfa. The stem is erect, about a foot high, knotty, leafy, a little compressed, smooth. Leaves linear, smooth, narrower than their long sheaths, of which the uppermost, in particular, is much inflated, embracing the base of the spike, which resembles that of a POLYPOGON. (See that article.) The flowers are sessile, disposed in four ranks, on a slender zigzag common stalk, or receptacle, their copious yellowish awns about half an inch in length, spreading every way. The outer valve of the corolla is clothed with copious soft spreading hairs.

TETRAPOLIS, in *Ancient Geography*. See CARPATHOS.

TETRAPOLIS, Attica, the name of a country of Greece, N. of Attica; in which, according to Strabo, were four towns built by Xanthus, when he reigned in this district of Greece; whence its name, from τετρα, four, and πολις, city.

TETRAPOLIS, Dorica, a country of Greece, in the Doride, between the country of the Etolians and that of the Enianes, according to Strabo.

TETRAPOLIS Syria, a country of Asia, in Syria, according to Strabo; it contained four principal towns, which had the same founder.

TETRAPTOTE, TETRAPTOTON, in *Grammar*, a name given to such defective nouns as have only four cases; such are *astus*, &c.

TETRAPYRAMIDIA, derived from τετρας, four, and πυραμις, a pyramid, in *Natural History*, the name of a genus of spars.

The bodies of this genus are spars influenced in their shape by an admixture of particles of tin; and are found in form of broad-bottomed pyramids of four sides.

Of this genus there is only one known species, which is usually of a brownish colour, and is found in Saxony; as also in Devonshire, Cornwall, and other counties of England, where there is tin. Hill.

TETRAPYRGIA, in *Ancient Geography*, a town of Cappadocia, in Galauria.—Also, a town of Africa, upon the coast of Marmarica, before Portus-Phycus, according to Strabo.

TETRARCH, TETRARCHIA, τετραρχης, formed of τετρα, four, and αρχη, rule, dominion, a prince who holds and governs the fourth part of a kingdom.

Such, originally, was the import of the title *tetrarch*; but it was afterwards applied to any petty king or sovereign; and became synonymous with *ethnarch*, as appears from the follow-

following considerations: 1. That Pliny makes mention of six tetrarchies within the cities of Decapolis. 2. That Herod's kingdom was only divided into three parts, which yet were called tetrarchies, and the sovereigns of them (Luke, iii. 1.) tetrarchs. 3. Josephus Antiq. Jud. lib. xiv. c. 23. tells us, that, after the battle of Philippi, Antony, going into Syria, constituted Herod tetrarch; and on medals the same Herod is called *tetrarch*.

TETRARRHENA, in *Botany*, so named by Mr. R. Brown, from *τετρα*, and *ῥηνη*, *male*, on account of the very remarkable character in this tribe, the grasses, of the four stamens, which Mr. Brown says he has ascertained by repeated examination.—Brown Prodr. Nov. Holl. v. 1. 209.—Class and order, *Tetrandria Digynia*. Nat. Ord. *Gramina*.

Eff. Ch. Calyx of two-valves, single-flowered. Corolla double; each of two valves, naked at the base. Nectary of two scales, opposite, alternate with the valves of the corolla. Stigmas feathery.

The inflorescence is a simple, equal, somewhat racemose spike. Flowers awnless.

1. *T. distichophylla*. Two-ranked Tetrandrous Grass. Br. n. 1. (Ehrharta distichophylla; Labill. Nov. Holl. v. 1. 90. t. 117.)—Flowers downy. Corolla ribbed, obtuse; the outermost valve half the length of the rest. Leaves straight, hairy as well as their sheaths. Stem branched at the base.—Native of Cape Van Diemen. The stem is hardly a foot high, with many erect leafy branches. Leaves lanceolate, acute, about an inch long, moderately spreading in two ranks. Spikes solitary, stalked, terminal, erect, about an inch in length, simple, the flowers almost all sessile, spreading in two rows.

2. *T. acuminata*. Pointed Tetrandrous Grass. Br. n. 2.—“Flowers smooth. Corolla ribbed; the outer glumes acute; one valve rather shorter than the inner glumes; the other longer, with a taper point. Leaves and their stems smooth. Stem branched.”—Found by Mr. Brown in the same country.

3. *T. juncea*. Rushy Tetrandrous Grass. Br. n. 3.—“Flowers smooth, imbricated. Calyx without ribs. Corolla ribbed, obtuse. Stem branched; straight and smooth like the leaves.”—From the southern coast of New Holland. Brown.

4. *T. lewis*. Smooth Tetrandrous Grass. Br. n. 4.—“Flowers smooth, distinct. Calyx ribbed, rather acute. Corolla obtuse, smooth, without ribs. Stems simple. Leaves smooth, flat, rather lax.”—Gathered by Mr. Brown in the same country with the last species.

TETRASARIUS, a word used by some of the medical writers, to express half an ounce.

TETRASPASTON, *τετρασπαστον*, in *Mechanics*, a machine in which are four pulleys. See **PULLEY**.

TETRASTATER, *τετραστατηρ*, in *Ancient Coinage*, a Grecian gold coin of Lyfimachus, Antiochus III., and of some of the Egyptian monarchs. It was the quadruple chrysolus (*χρυσος*), weighing about 530 grains, and current for 80 drachmas of silver, valued at about 3*l.*, now worth 4*l.* sterling. Some weigh 540 grains, which may be owing to the gold of such being of more alloy; though it may well be questioned, says Pinkerton (*Medals*, vol. i.), if they were ever meant to relate to the Attic standard.

TETRASTICH, *τετραστιχος*, a stanza, epigram, or poem, consisting of four verses.

TETRASTÆCHON, in *Botany*, a term often used by the Greek writers, and generally misunderstood by those who copy their accounts. Pliny has made an error in the description of the *euonymus*, which has confounded

two different shrubs together ever since, by mistaking the sense of this word, used by Theophrastus, in his account of it. He says, that the fruit is divided within into four orders or series of seeds; this he expresses by the word *tetraslachon*, which Pliny, supposing to be the same with the word *tetragonon*, has translated into *granum quadrangula figuræ*.

But this is by no means the sense of the word which was used by the Greeks, to express that a thing had *τεταρας ταξεις*, four rows, orders, or series of seeds in it: nor does it at all express the seeds being square, much less its being single, for the original derivation of the word was from the term *κατα χοιροι*, used in dances. These were composed of several series of persons, called *χοιροι*, *stæchi*; and every *stæchon* consisted of several persons, who all moved together. See **EUONYMUS**.

TETRASTYLE, formed from *τετρα*, *four*, and *στυλος*, *column*, in the *Ancient Architecture*, a building, and particularly a temple, with four columns in its front.

TETRASYLLABICAL, a word consisting of four syllables.

TETRATHECA, in *Botany, received that name from the writer of the present article, in allusion to the four cells of its anthers, the word being compounded of *τετρα*, and *θηκη*, *a case*, or *cell*. Mr. Brown indeed, in his *General Remarks on the Botany of Terra Australis*, p. 12, offers some observations tending to invalidate this name and character. But it appears to us, that they both derive confirmation from the consideration, of which we are well aware, that most anthers have four cells when young, though, as they burst lengthwise, the partition of each cell is obliterated. Whereas the peculiarity of our *Tetratheca*, admitted by our intelligent friend, consists in the four cells remaining unaltered, because the pollen is discharged by a terminal tube or orifice; nor is it of any great consequence that he has found, in some species, the partition to be obliterated, in an advanced state of the anthers. *Ceratopetalum*, for example, is a good name and a well-marked genus, though there is a species destitute of petals. With respect to the natural order, and the situation of the singular appendage to the seed, in the genus before us, we gladly profit by Mr. Brown's correction, hoping to be pardoned, though we may have made several false steps, in the totally strange wilderness of New Holland plants, which we were among the first, without any guide, to attempt to lay open to botanists.—Sm. Bot. of New Holl. 5. Exot. Bot. v. 1. 37. Willd. Sp. Pl. v. 2. 321. Ait. Hort. Kew. v. 2. 347.—Class and order, *Oëandria Monogynia*. Nat. Ord. akin to *Polygalæ*, a new order to which *Polygala* is referred; but in Mr. Brown's opinion constituting, along with another genus, a still different order, which, from the name destined for that genus, he chooses to denominate **TREMANDREE**, of which we propose to treat in its proper place.*

Gen. Ch. *Cal.* Perianth inferior, in four deep equal segments, deciduous. *Cor.* Petals four, obovate, equal, many times longer than the calyx. *Stam.* Filaments eight, inserted into the receptacle, very short, equal, erect, simple; anthers terminal; oblong, somewhat curved, much shorter than the corolla, with four longitudinal furrows, and as many cells, and terminating in a simple tubular beak, through which the pollen is discharged. *Pist.* Germen superior, very small, obovate, compressed; style vertical, cylindrical, simple, hardly so long as the anthers; stigma simple. *Peric.* Capsule obovate, compressed, of two cells and two valves, the partitions from the middle of each valve. *Seeds* one or two in each cell, oval, pendulous, with a naked scar, but crowned, at the opposite end, with a twisted crest.

Eff. Ch. Calyx four-cleft, inferior. Petals four. Anthers beaked, with four cells. Capsule of two cells and two valves, with partitions from their middle. Seeds crested, about two in each cell.

1. *T. juncea*. Rushy Tetratheca. Willd. n. 1. Ait. n. 1. Sm. Bot. of New Holl. 5. t. 2.—Smooth. Leaves alternate, lanceolate. Stem with sharp angles. Branches elongated, and almost naked.—Native of New South Wales, from whence we received drawings and specimens, through the hands of Dr. John White, soon after the settlement of the colony there. This plant was sent to Kew, by Mr. Peter Good, in 1803, and it is marked as flowering in July and August, being kept in the greenhouse in winter. The root is woody, small, perennial. Stems somewhat shrubby, much branched even from the base; the branches long, slender, very acutely angular, so as to be almost winged, leafy, smooth like every other part. Leaves generally few and small, acute, sessile, entire, with a strong mid-rib. Stipules none. Flowers scattered along the branches, on simple solitary red stalks, about an inch long, each from the bosom of a diminished leaf, and making a very elegant appearance. The calyx is red. Petals crimson or rose-coloured, three-fourths of an inch long. Anthers purplish-brown, tipped with yellow. We have a variety with white petals, the calyx and stalks of which preserve their usual colour.

2. *T. ericifolia*. Heath-leaved Tetratheca. Sm. Exot. Bot. v. 1. 37. t. 20.—Leaves whorled, linear, revolute, minutely toothed. Stem rough with ascending bristles. Flower-stalks and calyx very smooth. From the same country as the foregoing, and sent, with drawings, at the same time. This is of more humble growth than *T. juncea*, and much more leafy. The leaves are four, five, or more, in each whorl from top to bottom of the stem and branches, sessile, narrow, about half an inch long; their edges, and sometimes their upper surface, near the point, rough with minute teeth. Flowers rose-coloured, drooping, about half the size of the foregoing, on simple, solitary, axillary stalks, as long as the leaves. Anthers purple, with yellow tips, badly represented by the engraver, who mistook the original drawing of the section of an anther, for the germen, and altered it accordingly. Capsule ovate, emarginate. Seeds with a small white crest, mostly two in each cell.

3. *T. glandulosa*. Glandular Tetratheca. Sm. Exot. Bot. v. 1. 39. t. 21.—Leaves imperfectly whorled, lanceolate, revolute, toothed with little spines. Stem downy. Flower-stalks and calyx rough with glands.—Sent intermixed with the last, from New South Wales. The specimens of both appeared to have been burnt down to the ground, probably by fires made by the savages in the woods, and had grown up again; which proves them to be perennial plants, though scarcely shrubby. The size of the present species, and its general aspect, agree with *T. ericifolia*, but the corolla and anthers are of a darker tint. The stem is clothed with very short close down, by no means bristly; while the flower-stalks and calyx, instead of being smooth, are covered with glandular hairs. The leaves are rather broader, and less whorled, being often merely opposite, or even dispersed.

4. *T. thymifolia*. Thyme-leaved Tetratheca. Sm. Exot. Bot. v. 1. 41. t. 22.—Leaves whorled, lanceolate, toothed with little spines. Stem, flower-stalks, and calyx rough with ascending bristles.—From the same country. Rather larger than either of the two last, and readily distinguished, at first sight, by its broader less revolute leaves. The bristly hairs clothing the flower-stalks and calyx are its peculiarly distinguishing character. The flowers are of a fine crimson, with violet anthers, whose tips are yellow. Few

genera are more peculiar, or more elegant, than *Tetratheca*, and the species are all worthy of a place in our collections.

TETRATONON, is the Greek name of an interval of four tones; which in modern music is usually called the superfluous or sharp fifth.

TETRAX, in *Ornithology*, the name of a bird of the *otis* or bustard kind, called by some authors *anas campestris*, or the field-duck, and also little bustard; and by some others, the *canna*. See OTIS.

It is a very common bird in France, where it is called *canne patriere*: it is called *anas*, from its sitting on the ground, just as the duck does on the water. It is of the size of a pheasant, and has a beak like that of the common hen. It is taken with nets, as the partridge: it runs very swiftly, and, like the bustard, has no hinder toes. Its belly is white, and its back is variegated with grey, red, and black. It feeds on vegetables, and on small insects.

TETREUMA, in *Botany*, a name given by the people of Guinea to a species of shrub, very common among them, and used to cure whitlows. They dry the leaves, and reduce them to powder; and, moistening them with any liquor, apply them to the place. Petiver has called this *arbor Guineensis lauruflini facie*, from its great likeness to the common shrub which we call the laurufline. The leaves are opaque and stiff, and are an inch and a quarter broad, and two inches and a half long. These stand alternately on all sides of the stalk, and are fixed on short pedicles. The flowers grow out of the bosoms of the leaves, and stand in clusters in the manner of those of the common laurufline. Phil. Trans. N^o 232.

TETRICA, in *Ancient Geography*, a town of the Sabines, placed by Varro in the environs of mount Fiscellus, which lay northward. Servius on Virgil says, that it belonged to Picenum, because in his time, its limits had been changed. The Abbé Chaupé places it where we now find Leoneffa. There we find the terrible rocks, horrentes rupes, mentioned by Virgil.

TETRICUS MONS, a scraggy mountain of Italy, in the country of the Sabines. Pliny.

TETRINA, in *Geography*, a town of Russia, in the government of Archangel, near the White sea; 100 miles N.N.W. of Archangel.

TETRIX, in *Ornithology*, a species of *tetrao*; which see.

TETRODON, in *Ichthyology*, a genus of the Branchiostegi order of fishes, according to the arrangement of Gmelin; the characters of which are, that the jaws are long, divided at the tip; the branchiæ or gills have a linear aperture; the body is roughened beneath, and the ventral fins are wanting. The fishes of this genus, like the Chiodon, have the power of inflating their bodies at pleasure, by means of an internal membrane, and during this time the small spines of the sides and abdomen rise so as to be a defence against their enemies. They live principally on crustaceous and testaceous animals. Gmelin enumerates thirteen species.

SCELERATUS; the Noxious Tetrodon. Tetragonal, with very large head; length two feet or more. Found in the American and Pacific oceans, and considered as highly noxious, producing, when eaten, very severe symptoms.

TESTUDINEUS; a Tortoise-shell Tetrodon. Abdomen plane, smooth, and back with white curved furrows; length two feet; colour rufous-brown above, marked by numerous round pale blue spots; beneath blueish or ash-coloured, beautifully varied by longitudinal brown streaks; fins and tail bright ferruginous; the whole abdomen is furnished with numerous small spines, which, when the animal is undisturbed, are imbedded in corresponding cavities in the skin, but

but elevated, when the fish is alarmed and disturbs its body. Found in the Indian seas.

LAGOCEPHALUS; Hare Tetrodon. Abdomen aculeated; smooth body, and prominent shoulders; length twelve inches; thick in front; hinder parts tapering suddenly towards the tail; colour above yellowish-brown, beneath whitish with a silvery cast; across the back marked with short, black, or dark-brown bars, and over the sides with many, scattered, round, blackish spots; sides and abdomen beset with radiated spines; fins small, and tail slightly rounded. Found in the Indian and American seas; and straying into northern latitudes, are taken about the British coasts. This fish has the power of inflating the abdomen to a large size; and derives its name from the resemblance of its head to that of a hare.

LINEATUS. With brown and pale bands; length ten or twelve inches, square shape; and when inflated, like the last; body beset with small spines; colour grey on the abdomen, with longitudinal, deep-brown streaks; fins and tail as in the last species. Found in the Indian and American seas, and also in the river Nile.

ELECTRICUS. With red, green, and white spots; above brown, and beneath sea-green; yellow at the sides, and green fins; length seven or eight inches; eyes large, with red circles. Found in the Indian and American seas, among coral rocks; and when touched with the hand, affecting it with an electric or galvanic shock.

OCELLATUS. Ocellated on the shoulder-band; length six or eight inches; thick, ovate shape, contracting towards the tail; colour deep green above, paler on the sides and abdomen, which are whitish; across the middle of the back, as far as each pectoral fin, a broad black crescent, edged with yellow; dorsal fin situated on a round black spot with yellow edges; lateral line from beneath the eyes to the tail, which is small and roundish; under parts beset with many spines. Found in the Indian seas and adjoining rivers, particularly those of China and Japan; very poisonous in its nature, and it is prohibited to be eaten under very severe penalties by the emperor of Japan.

SPENGLERI. Head bearded with many cirri; lengthened shape; above brown-coloured, with roundish deep brown spots; abdomen tumid, whitish, and beset with small spines; with cirri or soft prominences dispersed about the upper parts of the body. Found in the Indian seas, ten or twelve inches in length.

HANKENII. With lower jaw longer than the upper; length eight or ten inches; like the former in general appearance; above brown-coloured, with small whitish clouds or spots; beneath whitish, with small spines. Found in the Indian seas.

OBLONGUS. Oblong, with equal jaws; length six inches; lengthened shape; colour whitish, with grey back, marked by many semi-decurrent brown bands; fins and tail cinereous; two lateral lines, one near the back, the other near the abdomen. Found in the Indian seas.

ROSTRATUS; Snouted Tetrodon. Both jaws elongated to the beak; length a few inches; oblong-ovate shape, contracting towards the mouth and tail; snout lengthened and slightly tubular; colour blueish-brown, beneath whitish; fore-part of the abdomen beset with spines, few over the back; fins brown. Found in the Indian seas.

LÆVIGATUS; Smooth Tetrodon. With the abdomen aculeated in front; a large species; blueish above, with two white stripes on each side; under parts white; from the mouth to the end of the pectoral fins aculeated; the other parts being smooth. Found in the American seas.

HISPIDUS. Entirely hispid, with bristly papillæ; length

two feet; shape, when inflated, like that of *T. lagocephalus*; colour whitish; upper parts marked across the back by three or four semi-decurrent brown bands; whole body beset with small spines. Found in the Mediterranean and Indian seas. Small remains of this species are said to occur among the petrifications of mount Bolca near Verona.

MOLA. Unarmed, sharp, compressed, rounded; a very short rounded tail; dorsal fin annexed to the anal, with oval spiracles. (See *SUN-Fish*.) Dr. Shaw has made a distinct genus of the sun-fish under the name of *cephalus*, the characters of which are, that the jaws are bony, and body terminating abruptly, so as to resemble the head of a fish. This genus comprehends the mola, or short sun-fish; the oblong sun-fish, with truncated body, or oblong diodon of Pennant (see *SUN-Fish*); the variegated, with whitish undulations and spots; and the Pallasian C. or silvery sun-fish, with brownish back, and spiny carinated abdomen. The mola, or short sun-fish, is a native of the European seas. Its general colour is brown, with a silvery cast on the sides and abdomen; the skin rough; the pectoral fins small, rounded, and placed horizontally; the dorsal and anal fins placed opposite, and of a lengthened shape, with rounded tips continued into the tail-fin. This fish is sometimes seen lying on its side, on the surface of the water, when it may be easily taken. In the Northern seas it arrives at a vast size, of the length of eight or even ten feet, and 500 pounds in weight: it is supposed to feed principally on shell-fish, and in the night it is said to exhibit a high degree of phosphoric splendour.

Of this there is a variety, *viz.* the *truncatus*, unarmed, smooth, compressed, oblong, with a very short tail, the dorsal and anal fins annexed, with lunated spiracles. This is the oblong sun-fish of Pennant.

STELLATUS; Spherical Grey Tetrodon. Whitish beneath, with the body beset with radiated spines: the tetrodon étoilé of Cèpede. Length twelve or fourteen inches; shape, when inflated, nearly spherical; colour greenish, deeper on the back, marked with dusky specks; under parts whitish; vent surrounded by a black circle; whole body covered with small stellated or radiated spines; dorsal fin rounded at the tip, and attached at the base by a kind of footstalk; tail oval. Found in the Indian seas. Shaw.

PUNCTATUS; Spherical Brown Tetrodon. With black specks, whitish abdomen, and very narrow dorsal fin: the tetrodon pointillé of Cèpede. Resembling the former. Found in the Indian seas. Shaw.

MELEAGRIS; Pintado Tetrodon. Brown, speckled with white. Found in the Indian seas, and when taken, making a kind of grunting noise, like several others of this and neighbouring genera.

TETSCHIN, or **TETZIN**, or *Dietzschin*, in *Geography*, a town of Bohemia, in the circle of Leitmeritz, on the river Elbe; 15 miles N. of Leitmeritz. N. lat. 50° 46'. E. long. 14° 17'.

TETSI, a town of Thibet; 27 miles E. of Lassa.

TETT, a place now in ruins, situated to the south of Azamore, on the northern extremity of the bay of Mazagan, in the empire of Morocco; the name signifies in Arabic Titus, and is therefore supposed to denominate the ruins of Titus, founded by the Carthaginians.

TETTER, a disease among animals, which is of the ring-worm kind, and which runs or spreads itself upon the skin in different directions, whence probably it has received the name. It attacks different parts, but is most commonly met with on and about the rump, not unfrequently running down upon the joints of the tail for some distance.

It is of a scabby itchy nature and appearance, and when neglected,

neglected, is said to have sometimes become of the quality of canker, in some sorts of animals. In cases where it fixes upon the more fleshy parts of the bodies of the animals, it is often attended with such troublesome itchings, as to cause them to rub themselves against posts, walls, and other places, until they rub off and destroy the very hair and skin of the parts. Nay, the animals will, it is said, sometimes even tear off the flesh with their teeth, if they can come at the parts.

The cure of the disease may mostly be accomplished by the use of a ball composed of from half a drachm to a whole one of calomel, or more, according to circumstances, in union with some sort of cooling purgative powder: or a powder constituted of crude antimony, æthiops mineral, and cremor of tartar, of each about half an ounce; which should be given once or twice a day in a quart of oat-meal gruel. At the same time, washing the parts well with Goulard water, and afterwards applying a little of an ointment composed of sulphur, blue ointment, and hog's-lard to them.

The animals should be well taken care of while the cure is going on.

TETTIGES, τειττιγες, *grasshoppers*, in *Antiquity*, a title the Athenians assumed to themselves. See *GEGENES*.

TETTIGOMETRA, in *Entomology*, a name by which the ancients called the nymph of the cicada, or *tettix*; and they named this nymph, from which they frequently saw that fly hatched, *tettigometra*, which signifies the *mother of the cicada*. See *HARVEST-FLY*, *CICADA*, and *VEGETABLE-FLY*.

TETTIGONIA, a word used by the ancients to express the smaller species of cicada, with which they were acquainted. They called the larger *acheta*.

It is generally supposed, that the tettigonia was the same with our smallest kind, called by the French *cigalon*; but M. Reaumur observes, that as the ancients knew two kinds of the cicada, we know three; and that our middle one seems to have been their tettigonia or small cicada, and that they were not acquainted with our smallest kind, or *cigalon*, which is not larger than a hornet.

TETTIGONIÆ of Linnæus. See *GRYLLUS*.

TETTIGONIÆ of Fabricius. See *CICADA*.

TETTUNANG, in *Geography*, a town of Germany, and principal place of a lordship of the same name, united with Mönchfort, ceded to Bavaria by the peace of Presburg; 8 miles N. of Lindau.

TETTOVA, a town of European Turkey, in Macedonia; 13 miles W. of Skopia.

TETTUA-MOTU, a cape on the E. coast of New Zealand, the N.E. point of Poverty bay. N. lat. 38° 36'. W. long. 181° 30'.

TETUAN, **TETAWAN**, or *Tetteget*, a town of Africa, in the empire of Morocco and province of El Garb, situated near the river Bufega, about a league and a half inland from the Mediterranean, and inhabited by Moors and Jews; who for the most part speak a corrupt Spanish, in which language their commercial negotiations are transacted. They are genteel in their persons and polite in their manners. The environs of Tetuan are planted with vineyards and gardens, which are kept in good order, and which produce more excellent fruits than those in other parts of the empire. From the raisins and figs the Jews distil an ardent spirit (called Mahaya), which, at the age of a year, resembles the Irish usquebaugh, and it is preferred to English brandy and rum. Of this they drink immoderately, and generally take a glass before eating. Leo Africanus attributes the foundation of this town to the people of Africa. It was

afterwards embellished, and the population increased, when the Moors were driven out of Spain. This was the place of residence for many of the consuls of the European powers, till the year 1770, when the reigning emperor, Seedy Mahomed, would no longer permit them to remain, nor again to establish themselves in the place. The port of this town has kept a trading communication with Gibraltar, whence the ships come to victual, when the wind is in the west, and does not allow them to make Tangiers. The shore of Tetuan is only safe when the wind is in the west, at which time ships ride securely; but when it veers to the east, they must remain here no longer. Our fleets often victual and water here, and this was the case with that of the immortal Nelson, previously to his victory in Aboukir bay. Tetuan is said to contain 16,000 people; 30 miles S.E. of Tangiers. N. lat. 35° 30'. W. long. 5° 20'.

TETYAN HEAD, a cape on the W. coast of the island of Mindanao; near which is a harbour that may be entered without danger. N. lat. 7° 20'. E. long. 124° 36'.

TEVAKUN, a town of Persia, in the province of Khorassan; 45 miles E.S.E. of Meschid.

TAVARA, a town of Naples, in Capitanata; 5 miles N.E. of Volturara.

TEUBER, or **TEUBERINN**, **ELISABETH**, in *Biography*, a celebrated German opera singer, and élève of the famous Tesi. She was chiefly attached to the court of Vienna, where she resided in 1772. She had sung at Naples in 1769 with great applause; but was peremptorily ordered by her physicians never to sing again. Her health had been so much impaired in Russia, where she had remained three years, that the whole faculty was unanimous in pronouncing that the exercise of her profession would be fatal. However, in spite of this prediction, she afterwards recovered her health and voice sufficiently, in a journey to Italy, to appear again on the stage at Naples in 1785; where, finding that her voice had somewhat lowered its pitch, she performed the principal man's part in contralto, to the entire satisfaction of the public. She was the daughter of a famous violinist in the emperor's service; she had lessons in singing from Haffe, in acting from the Tesi, and often sung in the operas of Haydn at Esterhazy.

TEUCHERN, in *Geography*, a town of Saxony, in Thuringia; 18 miles S.W. of Leipsic.

TEUCHITES, in *Botany*, a name used by some for the *scænanth* or *schænanth*, camel's hay, which ought to be written *teuchitis*. There is a city *Teuchis* in Egypt, near the borders of Arabia, and the geographers all mention a lake in the neighbourhood of this city; in this lake it is probable the schænanth might grow; and being gathered there, and sold in the adjoining city of Teuchis, the purchasers might distinguish it with an epithet formed of the name of the place where they bought it. See *SCÆNANTH*.

TEUCHTLACOT-ZANHQUI, in *Zoology*, a name by which the natives of some of the American nations call the rattle-snake.

TEUCRIUM, in *Botany*, an ancient name, whether applied to any species of this genus, or of any other, because the plant was discovered by Teucer the Trojan prince, or dedicated to him, or found in the country of Troy, sometimes called *Teucris*, we must humbly profess our inability to form any opinion or conjecture.—Linn. Gen. 287. Schreb. 384. Willd. Sp. Pl. v. 3. 13. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 606. Prodr. Fl. Græc. Sibth. v. 1. 390. Ait. Hort. Kew. v. 3. 365. Schreb. Unilab. 26. Pursh 405. Tourn. t. 98. Juss. 112. Lamarck Illustr. t. 501. (Polium; Tourn. t. 97. Chamædryd; Tourn.

TEUCRIUM.

t. 97.)—Class and order, *Didymia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven half way down into five acute, nearly equal, segments, gibbous on one side at its base, permanent. *Cor.* of one petal, ringent. Tube cylindrical, short, ending in an incurved throat. Upper lip erect, acute, divided throughout into two distant segments, divaricated towards each side: lower spreading, three-cleft; its lateral segments resembling the upper lip, nearly erect; the central one roundish, and very large. *Stam.* Filaments four, awl-shaped, longer than the upper lip of the corolla, ascending, curved, prominent between its divisions; anthers small, incumbent. *Pist.* Germen superior, deeply four-lobed; style thread-shaped, agreeing with the stamens in size and position; stigmas two, slender, acute. *Peric.* none, the unchanged calyx containing the seeds in its concave base. *Seeds* four, roundish, reticulated or wrinkled.

Eff. Ch. Upper lip of the corolla deeply divided, beyond its base, divaricated. Stamens prominent.

Obs. The upper lip of the corolla being so deeply divided, even below its base, into the tube itself, and its segments so far asunder, there seems to be no upper lip at all. The latter however is more truly the case in *Ajuga*, to which, and not to *Teucrium*, belongs the *Chamaepitys* of Tournefort; its upper lip being, in a manner, cut away. *Teucrium* of Tournefort has a bell-shaped calyx, and the middle segment of the lower lip of its corolla concave. *Polium* of the same author has its flowers collected into dense terminal heads. His *Chamaedrys* has axillary flowers, and a tubular calyx. *Marum* of Boerhaave has thyme-like leaves, and a peculiarly pungent smell. *Scordium* of Ray and Rivinus has the odour of garlic. *Iva* of Dillenius has the calyx very protuberant at the lower part. All these nevertheless form together a most natural and well-defined genus, whose qualities are more or less aromatic or bitter; its habit usually herbaceous, mostly perennial, often shrubby; leaves opposite, simple, though in some instances much divided; pubescence various, but hardly ever absent; flowers blue, red, yellow, or whitish, axillary, solitary or whorled, panicled or capitate; their incurved stamens and style always very conspicuous between the divisions of the upper lip.

Thirty-five species are enumerated in the fourteenth edition of Linn. Syst. Veg. from which *Chamaepitys*, *Iva* and *falicifolium* are to be removed to *Ajuga*. Willdenow, after making these deductions, has sixty-four. He follows Schreber and others, in making many more species out of the allies of *Polium*, than Linnæus would ever allow to be more than varieties. Two new ones from Crete are added in the Prodr. Fl. Græc. The genus is generally European, but not entirely so, and for the most part inhabits warm sunny climates. No attempt has been made to distribute it into sections. We shall indicate some traces of such, as we select the more curious or remarkable species for illustration, describing all the British as well as the new ones.

T. campanulatum. Bell-shaped Germander. Linn. Sp. Pl. 786. Willd. n. 1. Ait. n. 1. (*T. lupinum*, perenne, palustre, apulum, glabrum, foliis laciniatis, flore albo; Till. Pis. 163. t. 49. f. 1.)—Leaves many-cleft, nearly smooth. Flowers axillary, solitary. Calyx awned. Stem procumbent.—Native of moist situations, in Italy and the Levant. Miller appears to have cultivated it in 1728, but the true plant is now scarcely to be seen in our gardens, and is little known to botanists. The synonym of Tilli has no right to be marked as a variety, answering exactly to the Linnæan specimens and description, nor do we find any other figure of this species. Schreber seems to have mislead Willdenow,

to quote a synonym of Rivinus, which has no existence. This we find transcribed into Hort. Kew. with a correction of t. 14 for 24; though nothing but *T. Botrys* is there to be seen. No less incorrectly is Rivinus, t. 19, cited by Willdenow, after Schreber, for *T. orientale*; as Dr. Sims has noticed in Curt. Mag. 1279. *T. campanulatum* is a very distinct, perennial, herbaceous, nearly smooth, species, whose stems are square, leafy, more or less prostrate and creeping. Leaves an inch long, twice three-cleft, with bluntish, notched, slightly revolute segments. Flowers axillary, solitary, opposite, stalked, with a large, bell-shaped, rather pungent-pointed, calyx. The corolla is said to be white.

T. levigatum. Smooth Yellow Germander. Vahl Symb. v. 1. 40. Willd. n. 2.—Quite smooth. Lower leaves many-cleft; upper three-cleft, entire. Flowers axillary, solitary. Segments of the calyx oblong, without awns.—Gathered at Monte Video, by Commerfon, whose specimen is before us. This species is larger in all its parts than the foregoing, and appears to be herbaceous and erect, quite smooth, except a slight downiness, here and there, upon the young branches or stalks. Leaves stalked, an inch and half long, deeply divided into three wedge-shaped, jagged, blunt, very smooth and flat, lobes; the upper, or floral, ones much smaller and narrower, simply three-cleft. Flowers yellow. Segments of the calyx oblong-lanceolate, with one central rib and two marginal ones, acute, but not tipped with any awn or bristly point.

T. orientale. Great-flowered Germander. Linn. Sp. Pl. 786. Willd. n. 3. Ait. n. 2. Curt. Mag. t. 1279. (*T. orientale angustifolium laciniatum, flore magno subcæruleo*; Comm. Ran. 25. t. 25.)—Leaves deeply three-cleft, many-cleft, linear. Clusters terminal, compound. Flower-stalks horizontal, longer than the floral leaves.—Native of the Levant. Cultivated by Miller, and recently restored to our gardens by seeds obtained from Siberia, by Mr. Loddiges. The root is perennial. Several decumbent branches from the root bear leaves divided into many linear segments; but the foliage of the erect panicled flowering stem is doubly three-cleft below, simply above. Inflorescence terminal, racemose, compound, with small bracteaceous leaves. Flowers numerous, almost as large as those of *T. fruticosans* hereafter described, of a light purplish-blue. All the herbage, and even the corolla, is hairy or downy. We have already mentioned, under our first species, that the citation of Rivinus by Willdenow is an error.

T. Botrys. Cut-leaved Annual Germander. Linn. Sp. Pl. 786. Willd. n. 5. Ait. n. 3. Mill. Ic. t. 264. f. 1. (*Iva moschata, folio multifido*; Riv. Monop. t. 14. *Chamaepitys fœmina*; Ger. Em. 525.)—Leaves many-cleft. Flowers axillary, opposite, in pairs, turned one way. Calyx tubular, inflated and gibbous at the base.—Native of Germany, Switzerland, France and Italy, in dry fields. Root annual, fibrous. Herb hairy, branched from the bottom, erect. Leaves deeply pinnatifid, somewhat three-lobed. Flowers stalked, crimson, four together, making a sort of half whorl. The calyx becomes greatly enlarged after flowering, tubular, remarkably inflated below, and terminating in five triangular, awned, converging teeth.

T. trifidum. Trifid-leaved Germander. Retz. Obs. fasc. 1. 21. Willd. n. 7. Ait. n. 5. (*T. capense*; Thunb. Prodr. 95.)—Leaves hoary, in three deep linear segments. Stalks axillary, three-flowered. Calyx hoary, without awns.—Gathered at the Cape of Good Hope, by Thunberg and Masson. The latter sent seeds to Kew in 1791. The plant is shrubby, flowering most part of the summer, and kept in the greenhouse in winter. Its aspect is not unlike Winter Savory, but more hoary. The segments of the

TEUCRIUM.

leaves are an inch long, revolute, entire. *Flower-stalks* half the length of the leaves. Segments of the *calyx* elongated, lanceolate, revolute, single-ribbed, bluntly pointed, not awned. *Corolla* purplish. *Seeds* with a net-work of wrinkles over their surface.

T. Pseudo-chamæpitys. Racemose Slender-leaved Germander. Linn. Sp. Pl. 787. Willd. n. 8; excluding the synonym of Clusius. (*Chamæpitys alia*; Camer. Epit. 680. *Chamæpitys spuria* alterius altera icon; Dod. Pempt. 47.)—Leaves deeply once or twice three-cleft, linear, acute, revolute, hairy. Cluster terminal, simple. Bractæas three-cleft. Calyx hoary, awned.—Native of Spain, Barbary, and the south of France. The *stem* is shrubby, divided from the bottom into many ascending, leafy, square, mostly hairy branches. *Leaves* in very narrow, somewhat awned, segments, more or less hairy. *Flowers* much like those of *T. orientale*, but forming a simple terminal *cluster* at the top of each branch, with deeply three-cleft linear *bractæas*, usually as long as the *flower-stalks*. Lip of the *corolla* externally hairy. The *Pseudo-chamæpitys* of Clus. Hist. v. 2. 185. Lob. Ic. 385. f. 1. *Chamæpitys spuria altera*; Ger. Em. 526; the left-hand figure in Dod. Pempt. 47; all from the same wooden block; appears to us a different species from the above-described, with which we are unacquainted. There can be no doubt that the *T. mauritanum*, Linn. Sp. Pl. 787, entirely adopted from Shaw's rude figure, n. 575 of his Phyt. Afric. Specimen, is exactly the same with the real *Pseudo-chamæpitys* of Linnæus, which we have from Spain and Barbary, and which the cut of Camerarius, as well as the right-hand one of Dodonæus, clearly represents.

All the foregoing species, with a few more which may be found in Linnæus and Willdenow, apparently constitute a section of the genus before us, whose deeply-divided *foliage* gives them a peculiar and striking character. Their *inflorescence* nevertheless differs considerably, and on a more careful examination it will be found, that the racemose blue-flowered ones are most naturally akin to the *T. fruticans*, notwithstanding its undivided entire *leaves*; while the others are more related to some cut-leaved red-flowered species, with which we shall meet hereafter; inasmuch that no natural subdivision of this genus could be founded on the above character.

T. fruticans. Blue Tree Germander. Linn. Sp. Pl. 787. Willd. n. 9. Ait. n. 6. Sm. Fl. Græc. Sibth. t. 527, unpublished. (*T. latifolium*; Linn. Sp. Pl. 788. Curt. Mag. t. 245. *T. fruticans bæticum*; Clus. Hist. v. 1. 348. Dill. Elth. 379. t. 284. *T. bæticum*; Ger. Em. 659.)—Leaves ovate-lanceolate, entire; snow-white and cottony beneath. Flowers axillary, solitary. Segments of the *calyx* ovate, cottony at the back.—Native of the south of Europe and north of Africa. A hardy and common greenhouse plant in England, sometimes bearing our milder winters in the open air, especially near the sea. The *stem* is shrubby, bushy, three or four feet high, with straight, divaricated *branches*, clothed, like the backs of the *leaves* and *calyx*, as well as all the *stalks*, with peculiarly white, soft, dense down. The *leaves* vary in size and breadth, as may be seen in the plate of Dillenius, whose fig. 368. misled Linnæus to make a species, by the name of *latifolium*, which is but a trifling variety. The upper surface of the *leaves*, and inside of the *calyx*, are dark-green, usually quite smooth. *Flowers* large and handsome, of a fine blue, coming out at all times of the year: the middle segment of their lower lip sometimes deeply cloven.

T. brevifolium. Short Hyssop-leaved Germander. Schreb. Vertic. Unilab. 27. Willd. n. 10. Sm. Fl. Græc. Sibth. t. 528, unpublished. (*Rosmarinum stœchadis facie*; Alpin. Exot.

103. t. 102. *Polio retto di Candia*; Pon. Bald. 156.)—Leaves lanceolate, revolute, entire, obtuse, hoary. Flowers solitary. Calyx without awns.—Native of rocks in Crete, near the sea-shore. The *stem* is shrubby, with copious spreading, square, leafy branches. *Leaves* about an inch long, of a hoary green on both sides, veiny. *Flowers* on slender, solitary, simple stalks, from the bosoms of the upper leaves. *Corolla* bluish-coloured, with purple veins. Segments of the *calyx* revolute and blunt. Schreber and Willdenow cite, under this species, *T. frutescens*, *stœchadis arabicæ folio et facie*; Tourn. Cor. 14. Rivin. Monop. t. 20; which is correct as to Tournefort, but no such thing occurs in Rivinus. If we had not consulted, in Sir Joseph Banks's library, the most perfect copy of his work known to exist, we should not speak so decidedly on this head.

T. creticum. Rosemary-leaved Germander. Linn. Sp. Pl. 788. Willd. n. 11. Sm. Fl. Græc. Sibth. t. 529, unpublished. (*T. hyssopifolium*; Schreb. Vertic. Unilab. 28.)—Leaves linear-lanceolate, revolute, entire, obtuse; white and cottony beneath. Flowers often two or three together. Calyx cottony, spinous.—Native of Crete, Cyprus, and Egypt. A taller, larger *shrub* than the last, some of whose synonyms were confounded with it by Linnæus. Its habit and foliage much resemble Rosemary. The *flowers* are light purple, or pink, and form long leafy *clusters*, at the ends of the *branches*, being either solitary, or two or three together, on short downy *stalks*, from the bosoms of the upper *leaves*. The *calyx* is cottony without; green within; and has short spinous points.

T. Marum. Marum Germander, or Cat-thyme. Linn. Sp. Pl. 788. Willd. n. 12. Ait. n. 7. (*Pseudo-Marum*; Rivin. Monop. Irr. t. 13, not t. 40, which is *Thymus Maltichina*. Marum Cortusi; Bauh. Hist. v. 3. 242.)—Leaves ovate, acute, entire, stalked, cottony beneath. Flowers racemose, in pairs, turned one way. Calyx woolly.—Native of Spain, and the isles of Hyeres. Frequent in greenhouses, where it is very hardy, being cultivated for the sake of its peculiarly pungent scent, which powerfully induces sneezing, and which renders it not less grateful to cats than Valerian. The *stem* is bushy, of humble growth, with round hoary branches. *Leaves* a quarter of an inch long, of a hoary green on the upper side. *Flowers* crimson.

T. quadratum. Little Square-leaved Germander. Schreb. Vertic. Unilab. 36. Willd. n. 13. Sm. Fl. Græc. Sibth. t. 530, unpublished. (*T. ramosissimum*; Desfont. Atlant. v. 2. 4. t. 118.)—Leaves obovate-rhomboid, deeply toothed; cottony beneath. Flowers axillary, solitary, deflexed. Calyx woolly.—Native of fissures of rocks, in Spain, Barbary, and Crete. A small, decumbent, branching *shrub*, whose *leaves* are not half an inch long; green above; white beneath. *Flowers* pink, their *calyx* bent down, so as to make a right angle with its *footstalk*, and then recurved. Segments of the upper lip of the *corolla* advanced towards those of the lower in a remarkable degree. *Style* reflexed.

T. Laxmanni. Laxmann's Germander. Linn. Syst. Veg. ed. 13. 439. Willd. n. 16. Ait. n. 10. Marck. von Bieberst. Taur. v. 2. 35. "Waldst. and Kitaib. Hung. v. 1. 71. t. 69."—Leaves elliptic-oblong, villous, ribbed, nearly entire. Flowers axillary, solitary, opposite, turned one way.—Native of Siberia, Hungary, &c. We notice this species here merely to express our concurrence with the opinion of the able author of the Flora Taurico-Caucasica above cited, that it certainly belongs to *Ajuga*, as well as the *T. salicifolium*, Linn. Mant. 80, already referred thither by Schreber and Willdenow. The two species are very nearly akin, and answer in character and habit entirely to *Ajuga*, and not to *Teucrium*.

T. Arduini.

TEUCRIUM.

T. Arduini. Arduino's Germander. Linn. Mant. 81. Willd. n. 20. Sm. Fl. Græc. Sibth. t. 531, unpublished. (*T. foliis ovato-crenatis, subhirsutis, petiolatis, caulibus spicâ flavescente pilosâ terminatis*; Arduin. Spec. 1. 12. t. 3. *Scutellaria cretica*; Linn. Sp. Pl. 836. Willd. Sp. Pl. v. 3. 176. Ait. Hort. Kew. v. 3. 429. *Cassida cretica fruticosa, catarix folio, flore albo*; Tourn. Cor. 11.)—Leaves ovate, serrated, hairy. Clusters densely imbricated, cylindrical, with linear bractæas, longer than the flowers. Upper segment of the calyx dilated, heart-shaped; two lowest setaceous.—Native of Crete, and of the shady woods of the Bithynian Olympus. It appears to have been cultivated by Miller in 1729. Although Linnæus, in referring this plant, after Tournefort, to *Scutellaria*, perceived it to be a *Teucrium*, neither he nor any one else, till lately, suspected it to be described twice over in his works. This we discovered by a comparison of original specimens. The stem is herbaceous, not shrubby, square, cross-branched, leafy, rough with spreading hairs. Leaves stalked, not unlike those of Balm in size, form, and colour. Clusters from one to four inches long, near an inch in diameter, solitary at the ends of the branches, erect, of innumerable crowded white flowers. The calyx is hairy, suddenly bent downwards at its taper base, then horizontal, its border very unequally five-cleft; the upper segment broad, as in *Scutellaria*, reflexed at the sides, tipped with a bristle; two next short, triangular; two lowest long, narrow, with pungent points.

T. canadense. Nettle-leaved Hoary Germander. Linn. Sp. Pl. 789. Willd. n. 21. Ait. n. 13. Pursh n. 1. (*Chamædrys canadensis, urticæ folio, subtus incano*; Tourn. Inf. 205.)—Leaves ovate-lanceolate, stalked, sharply serrated, downy on both sides; hoary beneath. Cluster terminal, dense, somewhat whorled. Bractæas ovate, shorter than the flowers. Segments of the calyx nearly equal.—In low grounds, on the borders of ponds and lakes, from Canada to New York, perennial, flowering in July and August. The habit of the leaves and inflorescence is like that of some spiked *Veronica*. At the insertion of each pair of footstalks, the stem is surrounded with a ring of prominent hairs. The calyx is bell-shaped, with five broad, nearly equal, segments. Corolla purple.

T. virginicum. Virginian Germander. Linn. Sp. Pl. 789. Willd. n. 22. Ait. n. 14. Pursh n. 2. "Schkuhr Handb. t. 160." (*T. virginianum melissophyllum, floribus cæruleis*; Pluk. Almag. 363. Phyt. t. 318. f. 1; with a very faulty representation of the corolla.)—Leaves ovate-oblong, serrated, downy; the upper ones sessile. Spikes crowded, whorled. Bractæas the length of the calyx.—In low grounds and bogs, from New York to Carolina, perennial, flowering from June to August. It very much resembles the last. Pursh.—Miller is said to have cultivated both these North American species in 1768. We have seen only the former.

T. abutiloides. Mulberry-leaved Germander. L'Herit. Stirp. v. 1. 84. Willd. n. 27. Ait. n. 17. Jacq. Hort. Schoenbr. v. 3. 58. t. 358.—Leaves heart-shaped, acute, crenate, downy. Clusters axillary, not longer than the footstalks.—Discovered by Mr. Masson in Madeira, from whence it was brought to Kew, in 1777. It flowers in the greenhouse in April and May, and is conspicuous for the large size of its leaves, four or five inches long, on densely downy footstalks, half that length. The flowers are no less remarkable for their golden hue, and their situation in dense, solitary, lateral, stalked clusters, which rarely equal the footstalks in length.

T. Scorodonia. Wood Germander, or Wood Sage. Linn. Sp. Pl. 789. Willd. n. 28. Fl. Brit. n. 1. Engl. Bot. t. 1543. Curt. Lond. fasc. 5. t. 40. Fl. Dan. t. 485.

(*Scorodonia*; Rivin. Monop. Irr. t. 12. S. five *Salvia agrestis*; Ger. Em. 662.)—Leaves heart-shaped, serrated, stalked, hairy. Stem erect. Flowers leaning to one side, in lateral and terminal clusters.—Very common in dry heathy ground, and sandy woods, throughout Europe, from Norway to Greece, flowering in July and August. Linnæus seems to have recollected this plant with delight in the fields of Hartecamp, where the garden of his friend Clifford had been to him a real paradise. The root is creeping and perennial. Herb a foot or two in height, dark green, hairy, bitter, with a strong scent like hops, for which it is said to be not a bad substitute in brewing. We wish nothing worse had ever been used. The long aggregate clusters of flowers are rendered conspicuous by the contrast of the pale yellow corolla and purple stamens. The upper segment of the calyx approaches in form and breadth to what we have pointed out as so remarkable in *T. Arduini*.

T. betonicum. Hoary Germander. Ait. ed. 1. v. 2. 279. ed. 2. n. 19. Willd. n. 30. L'Herit. Stirp. v. 1. 83. t. 40. Curt. Mag. t. 1114. (*T. betonicæfolium*; Jacq. Coll. v. 1. 145. t. 17. f. 2.)—Leaves ovate-lanceolate, bluntly serrated, stalked, soft and downy; hoary beneath. Stem shrubby. Clusters aggregate, terminal. Bractæas lanceolate, entire. Native of Madeira. A very handsome greenhouse shrub, introduced by sir Joseph Banks, in 1775, flowering most part of the summer, and easily propagated by cuttings. The crimson flowers are elegantly contrasted with the hoariness of the herbage; the upper surface of the leaves being greener than the rest. The segments of the upper lip of the corolla being broader and blunter than usual, some doubts have been started whether this species belonged to *Teucrium* or to *Ajuga*, or whether these genera were really distinct. To this we would answer, that the habit of the latter is peculiar, and its essential character no less clear, consisting in a short notched upper lip, instead of the remotely-lobed one of *Teucrium*. We believe moreover that the central lobe of the lower lip is always divided and divaricated in *Ajuga*.

T. massiliense. Apple-scented Germander. Linn. Sp. Pl. 789. Willd. n. 32. Ait. n. 21. Jacq. Hort. Vind. v. 1. 41. t. 94. (*T. n. 6*; Gerard. Gallopr. 277. t. 11.)—Leaves ovate, rugged, hoary, strongly crenate. Stem erect. Flowers turned to one side, in lateral and terminal, upright clusters.—Native of the isles of Hyeres, but scarcely known in any other country, nor is it often to be seen in gardens. The stems are a foot high. Leaves stalked, bluntish, hardly an inch long. Flowers small, light crimson. Upper segment of the calyx broad-ovate. The whole herb is clothed with a hoary, soft, velvet-like pubescence, and when touched exhales a very powerful and peculiar scent, like mellow apples, and therefore, to many people, not agreeable, though combined with a spicy fragrance. Gerard's plate, like the others in his book, is very finely executed.

T. Scordium. Water Germander. Linn. Sp. Pl. 790. Willd. n. 34. Fl. Brit. n. 2. Engl. Bot. t. 828. Woodv. Med. Bot. t. 57. Fl. Dan. t. 593. (*Scordium*; Rivin. Monop. Irr. t. 11. Ger. Em. 661.)—Leaves oblong, sessile, with tooth-like serratures. Flowers axillary, stalked, in pairs. Stem procumbent.—Native of marshy places in various parts of Europe, but rare in England, except in the Isle of Ely. It appears to be the true *σχορδίου* of Dioscorides, retaining a similar appellation, among the modern Greeks, and occurring, as Dr. Sibthorp observed, in Crete, Zante, and Asia Minor. The root is perennial and creeping. Herb decumbent or prostrate, hairy, and somewhat hoary, very bitter, with a strong, unpleasent, garlic-like scent. Flowers pale purple, in opposite pairs, from the bosoms of most of the

the *leaves*. This herb has formerly been celebrated for its deobstruent and tonic qualities, but is now out of medical use, except perhaps in the recesses of the country.

T. scordoides of Schreber, Willd. n. 35, seems to us, without doubt, a variety of the last, as it is made in Prodr. Fl. Græc. v. 1. 393.

T. Chamædrys. Wall Germander. Linn. Sp. Pl. 790. Willd. n. 36. Fl. Brit. n. 3. Engl. Bot. t. 680. Woodv. Suppl. t. 243. (Chamædrys; Rivin. Monop. Irr. t. 10. f. 2. Tourn. Inst. t. 97; a much better figure. C. major latifolia; Ger. Em. 656.)—Leaves nearly ovate, stalked, deeply crenate. Flowers axillary, three together, stalked. Stem round, hairy.—Found on dry rocks and old walls in the more temperate or warm countries of Europe. It is abundant on the old city wall, on the north side of Norwich, as well as here and there in other parts of England, but not universally. Dr. Sibthorp observed the plant in dry stony places, throughout Greece and the isles of the Archipelago, where it still retains nearly the same appellation of *χαμαίδρυς*, recorded in Dioscorides. It flowers in July and August, and has a perennial creeping root. The stem is bushy, rather diffuse, and slightly shrubby, a span high. Leaves of a full shining green, slightly hairy, deeply crenate and cut. Flowers crimson, numerous, more handsome than those of *T. Scordium*, with which species the present has been supposed nearly to agree in virtues. It is equally bitter, but more agreeably, though less powerfully, scented.

T. lucidum. Shining Germander. Linn. Sp. Pl. 790. Willd. n. 39. Ait. n. 25. Sm. Fl. Græc. Sibth. t. 532, unpubl. (Chamædrys alpina frutescens, folio splendente; Tourn. Inst. 205. Magnol. Hort. 52. t. 9.)—Leaves ovate, stalked, deeply crenate, smooth and shining. Flowers axillary, three together, stalked. Stem square, erect, nearly smooth.—Native of alpine vallies in Savoy and Provence. Found by Dr. Sibthorp on Parnassus, and other Grecian mountains, as well as in the island of Cyprus. The tall, erect, square stems, often quite smooth; numerous whorls of large crimson flowers; and shining leaves, of which the upper or floral ones are more numerous quite entire; all render this plant, at first sight, decidedly different from the last, and yet they are very nearly related, so that an essential difference is difficult to seize, and perhaps none that has yet been indicated is invariably constant.

T. flavum. Yellow Shrubby Germander. Linn. Sp. Pl. 791. Willd. n. 41. Ait. n. 26. Sm. Fl. Græc. Sibth. t. 533, unpubl. (Teucrium; Rivin. Monop. Irr. t. 10. f. 1. Chamædrys frutescens major, floribus ochroleucis; Morif. sect. 11. t. 22. f. 1.)—Leaves ovate, crenate, downy. Whorls six-flowered, composing terminal clusters, with ovate, concave, entire bractæas. Stem shrubby, downy.—Native of rocks and old walls, in the south of Europe, and north of Africa; abundant in the Archipelago, and on the walls of Rome. The stem is woody, branched, erect, about two feet high; its branches leafy, bluntly quadrangular, clothed with very soft, velvet-like, curved pubescence, as is the whole of the herbage. Leaves stalked, hardly an inch long; tapering and entire at the base. Flowers pale yellow, composing long, whorled, erect clusters, with pale-green bractæas, about equal to the calyx. The teeth of the latter are nearly equal. Upper segments of the corolla edged with red.

T. bicolor. Two-coloured Chili Germander. (*T. heterophyllum*; Cavan. Ic. v. 6. 56. t. 577.)—Leaves wedge-shaped, obtuse; undivided or cut. Flowers axillary, solitary. Calyx nearly regular, with ten strong ribs.—Gathered by Louis Née, in the neighbourhood of Talcahuano, in Chili, flowering in November and December. We have

a wild specimen from the late abbé Cavanilles, whose specific name we are obliged to change, there being already a *T. heterophyllum*, Willd. n. 37. The stem is shrubby, almost six feet high, with square leafy branches, clothed, like the calyx, stalks, and under side of the foliage, with very short dense pubescence. The leaves are about an inch long, nearly smooth on the upper side, various in breadth; the broadest deeply and coarsely cut; the rest undivided and entire; the lower ones on short stalks; the upper sessile. Flowers from the bosoms of the upper leaves, on shortish, round, finely downy stalks. Calyx cut almost half way down into five, nearly equal, acute, ovato-lanceolate segments, each with a strong mid-rib; its tube having five intermediate ribs besides. Corolla externally hairy, white, the middle of its lower lip of a violet red.

T. montanum. Dwarf Mountain Germander. Linn. Sp. Pl. 791. Willd. n. 42. Ait. n. 27. Sm. Fl. Græc. Sibth. t. 534, unpublished. (*Ajuga folio integro*; Rivin. Monop. Irr. t. 15. Polium septimum; Clus. Hist. v. 1. 363. f. 1, 2. P. lavandulæ folio; Ger. Em. 655. f. 2, 3.)
β. *T. fupinum*. Linn. Sp. Pl. 791. Willd. n. 43. Ait. n. 28. Jacq. Auftr. t. 417. (*P. montanum octavum*; Clus. Hist. v. 1. 363. P. montanum minimum; Ger. Em. 655.)

Corymbs terminal. Leaves linear-lanceolate, somewhat revolute, almost entire; cottony beneath. Calyx reticulated, ten-ribbed, slightly downy, with spinous teeth.—Native of dry mountainous or alpine situations, in Germany, Switzerland, France, Spain, and Greece; sometimes, though rarely, preserved in pots, under a frame, in our more curious gardens. A dwarf bushy shrub, like Thyme, with a strong woody root, and many diffuse, downy, leafy stems. Leaves crowded, opposite, stalked, hardly an inch long, very rarely notched, various in breadth; green, convex, and nearly smooth, above; veiny, very white and cottony, beneath. Flowers in dense, sessile, solitary corymbs. Calyx tubular, pale, with equal, spreading, tapering, pungent teeth, from whose intermediate sinuses the veins spread star-wise. Corolla pale buff-coloured, the segments of its upper lip veined with red.

Schreber has long ago united *T. montanum* and *fupinum*; nor was Linnæus ignorant of their near affinity; though in this instance, as in every thing relative to alpine plants of the south of Europe, which he had rarely examined alive, he was disposed to give up his own opinion, to that of practical observers. Clusius having represented *T. fupinum* so different in size and habit from *montanum*, might help to mislead following botanists; but in truth they hardly deserve to be distinguished as varieties, *fupinum* being only rather less luxuriant, with narrower leaves, which indeed vary on the very same root. The species before us has lent a specific name to some other plants, as *Andromeda polifolia* of Linnæus, and *Menziesia polifolia* of Jussieu, which have no similitude to the true ancient *Polium* hereafter described, but greatly resemble this.

T. pyrenaicum. Pyrenean Germander. Linn. Sp. Pl. 791. Willd. n. 45. Ait. n. 29.—Corymbs terminal. Leaves orbicular, crenate, hairy; entire and slightly wedge-shaped at the base. Calyx-teeth tapering, fringed.—Native of the Pyrenées. Cultivated by Miller in 1731, at Chelsea garden, where we have seen it a few years since, yet there seems to be no certain figure of this beautiful plant extant. Its habit is somewhat like the last, but the leaves totally different, being almost orbicular, and from half an inch to an inch in diameter, flat, green, veiny and hairy. Flowers in dense convex tufts, variegated with pale yellow and purple; the ribs and teeth of the calyx fringed with long bristly hairs.

Whether

TEUCRIUM.

Whether Schreber's *T. rotundifolium*, Willd. n. 46, to which the figures of Boccone and Barrelier, cited for the former, are said to belong, be more than a variety, we have no means of determining.

T. Polium. White Poley Germander. Linn. Sp. Pl. 792. Willd. n. 52. Ait. n. 31, Sm. Fl. Græc. Sibth. t. 535, unpublished. (*T. Teuthrion*; Schreb. Unilab. 46. *Polium montanum*; Ger. Em. 653, 654. *P. montanum album ferratum*, &c.; Barrel. Ic. t. 1074.)—Heads roundish, leafy. Leaves sessile, oblong, obtuse, convex, bluntly crenate, densely woolly. Calyx very woolly, obtuse, pointless.—Native of mountains in Italy, Spain, and the south of France; very common in Greece, the Archipelago, and throughout the Levant; rarely seen in our gardens, being impatient of wet. The root is woody and very strong. Stems numerous, a span long, ascending, erect, or partly decumbent, round, clothed, like the rest of the herbage, with extremely soft, white, woolly down. Leaves numerous, opposite, half an inch or an inch long, thick and woolly, their edges remarkably deflexed, with strong, round, recurved teeth; the base slightly wedge-shaped, scarcely stalked. Flowers numerous, in dense, sessile, terminal, often aggregate, heads, or short spikes, intermixed with leaves; the lower heads usually stalked. Calyx very woolly and obtuse. Corolla white, with a yellow palate.

Schreber, who is followed by Willdenow, makes numerous species out of the reputed varieties of this plant, of which we are unable, for want of sufficient means of examination, to form an opinion. The characters given do not satisfy us, nor do the specimens we have seen afford better.

The most striking of the whole is *T. aureum*, Schreb. Unilab. 43. Willd. n. 48. Ait. n. 30. Cavan. Ic. v. 2. 16. t. 17, remarkable for the golden tint on its heads and upper leaves. This has usually a solitary head or spike, and perhaps the calyx-teeth are more slender and acute than in the common *T. Polium*, which merits inquiry. On the other hand, *T. capitatum*, which we shall next describe, approaches nearly to some of the above-mentioned varieties, so that perhaps they ought to be referred to it, rather than to *Polium*.

T. capitatum. Purple Poley Germander. Linn. Sp. Pl. 792. Willd. n. 56. Ait. n. 32. Cavan. Ic. v. 2. 17. t. 119. Sm. Fl. Græc. Sibth. t. 536, unpublished. (*Polium monspessulanum*; Bauh. Hist. v. 3. 299.)—Heads roundish, leafy, lateral and terminal, stalked. Stem cross-branched. Leaves sessile, linear-oblong, obtuse, convex, crenate, hoary. Calyx woolly, oblong, obtuse, pointless.—Native of hills in Siberia, Spain, the south of France, Zante, Cyprus, and Greece. This is of a more slender habit than the last, less woolly, and more hoary, with purple flowers, a more elongated tubular calyx, and narrower leaves. The tube of the corolla also is longer, and much less bell-shaped, or inflated in the throat. It is nearly related to *T. Polium*, but surely a distinct species.

T. cuneifolium. Wedge-leaved Poley Germander. Sm. Prodr. Fl. Græc. Sibth. n. 1311. Fl. Græc. t. 537, unpublished.—Heads terminal, dense. Leaves rounded, deeply crenate; wedge-shaped at the base; woolly all over. Calyx blunt, pointless.—Gathered by Dr. Sibthorp, on the Spachiote mountains of Crete. The general outline of the plant answers to *T. rotundifolium*, Willd. n. 46; but that is a far less woolly plant, with a pointed calyx, and not allied to the *Polium* tribe. The present has round, trailing, shrubby, cross-branched stems, a foot or more in length. Every part of the herbage is covered with thick, white, soft, woolly or velvety down. Leaves, with their stalks, an inch long. Flowers snow-white, in aggregate terminal

heads. Calyx tubular, with short rounded teeth. Segments of the upper lip of the corolla large, as long as the stamens, which they embrace, and partly conceal. Anthers red.

T. alpestris. Sharp-toothed Alpine Poley Germander. Sm. Prodr. Fl. Græc. Sibth. n. 1312. Fl. Græc. t. 538, unpublished.—Flowers axillary, solitary. Leaves wedge-shaped, rounded, deeply crenate, downy. Stem tufted, much branched.—Found by Dr. Sibthorp, upon the most lofty summits of the Spachiote mountains of Crete. The root is woody, dividing at the crown into innumerable strong, woody, depressed stems, which bear a dense tuft of ascending, leafy, downy branches, hardly a finger's length. Leaves stalked, greyish, about half an inch long, obtuse. Flowers opposite, on short stalks, from the bosoms of two or three of the uppermost pair of leaves. Calyx tubular, finely downy. Tube, throat, and upper lip of the corolla, pale yellow; lower lip white, its middle segment deeply concave.

T. pumilum. Rosemary-leaved Poley Germander. Linn. Sp. Pl. 792. Willd. n. 61. (*Polium montanum pumilum rubrum*; Barrel. Ic. t. 1092, 1093.)—Heads terminal, solitary, sessile, leafy. Leaves crowded, sessile, linear, revolute, smooth; downy beneath. Stems ascending, woolly. Calyx pointed.—Native of hills in Spain, flowering in July and August.—From the woody perennial root, spring several, more or less erect, simple or branched, leafy stems, three or four inches long, clothed with dense, soft, white wool. The leaves are hardly an inch long, crowded and somewhat imbricated, in four rows, narrow, strongly revolute, obtuse; convex, green and polished on the upper side; concave, with a downy rib, just visible beneath. Calyx ribbed, downy, with short, thick, spinous points. Tube of the corolla slender, downy, as well as the outside of the limb.

We are quite unable to imagine how *T. Libanitis* of Schreber, Willd. n. 60. Cavan. Ic. v. 2. 17. t. 118, came to be distinguished from *pumilum*, as there does not appear to be the least difference between them, except the stem of *Libanitis* being more erect; but that circumstance is evidently variable. *T. verticillatum*, Cavan. t. 198. Willd. n. 59, seems also but a variety; though we presume not to determine this without seeing a specimen.

T. spinosum. Thorny Germander. Linn. Sp. Pl. 793. Willd. n. 64. Ait. n. 33. Sm. Fl. Græc. Sibth. t. 539, unpublished. (*Chamædryas spinosa*; Bauh. Prodr. 117. *Scordium spinosum odoratum*; Cornut. Canad. 123. t. 124. Barrel. Ic. t. 202. *S. spinosum*; Cavan. Ic. v. 1. 19. t. 31.)—Stem and branches spinous, hairy. Flowers axillary, opposite. Upper segment of the calyx ovate; the rest awl-shaped, spinous.—Native of fields and hilly places in Spain and Portugal. Dr. Sibthorp met with it in fields between Smyrna and Bursa. The root is annual. Stem branched copiously from the very bottom, about a foot high, bushy, the branches opposite, crossing each other in pairs, spreading, square, clothed with very soft prominent hairs, tipped with strong spines, and furnished with smaller lateral ones, particularly at the insertion of the leaves and flowers. Leaves sessile, deflexed, small, oblong, obtuse, notched, green, hairy. Flowers numerous, solitary or in pairs, from the bosoms of the diminished or upper leaves, each on a short, round, hairy stalk. Calyx deflexed and bent at the base, then horizontal and somewhat bell-shaped; its upper segment very broad, ribbed, spinous-pointed, erect, or rather reflexed, the four others shorter, prominent, ascending, pungent. Corolla white, with red stripes on its upper lip; the middle segment of the lower very large, slightly concave; the base of the tube globular.—The flowers are by no means reversed, *resupinati*; in Sibthorp's figure of this species, though

Læfing so describes them, and led Linnæus to adopt that character. His *T. mucronatum*; Sp. Pl. 793, differs in no respect from the *spinofum*, to which therefore we have transferred its synonyms.

TEUCRIUM, in *Gardening*, furnishes plants of the under-shrubby and herbaceous kinds, among the great number of which, the species following are the most generally cultivated: the yellow-flowered shrubby germander (*T. flavum*); the sage-leaved germander, or wood-sage (*T. icorodonia*); the nettle-leaved germander (*T. canadense*); the dwarf mountain germander (*T. montanum*); the Pyrenean germander (*T. pyrenaicum*); the poley (*T. polium*); the round-headed germander (*T. capitatum*); the dwarf germander (*T. pumilum*); the narrow-leaved tree-germander (*T. fruticans*); the broad-leaved tree-germander (*T. latifolium*); the Cretan germander (*T. creticum*); and the common marum or cat-thyme (*T. marum*).

There is a variety in the first sort which is hairy, with yellow flowers, with pale white flowers, and with purple flowers.

In the fourth sort there is likewise a variety with much smaller leaves, which are hoary on their under side.

Also in the sixth sort there are several varieties; as the common yellow poley, which has the stalks rather herbaceous and trailing, about six inches long, and hoary: leaves woolly, about half an inch long, some wedge-shaped, others oblong, ending in obtuse points, and crenate towards their ends: the flowers collected in oblong thick spikes at the end of the branches, of a deep yellow colour, and appearing at the beginning of June. This grows naturally in Spain. The narrow-leaved yellow poley, which has woody stalks, erect, branching, and covered with a hoary down, rising six or eight inches high; the leaves linear, woolly, about half an inch long, having sometimes two or three slight indentures on their edges; the flowers collected in roundish spikes at the end of the branches; they are bright yellow, have woolly calyces, and appear in June and July. It grows naturally in Spain and Portugal. The white poley, which has the stems a foot long, and trailing: the leaves are a little cottony, entire on the sides, but toothed at the end: the flowers are pretty large, white, tinged a little with purple. It is a native of the south of France. There is also the purple poley.

And there is a variety in the seventh sort which has an erect branching stalk, that rises a foot high; the lower part becomes woody, but the upper is herbaceous: the leaves are linear-lanceolate, about an inch long, crenate, of a pretty thick consistence, and a little woolly: the flowers collected in a corymb at the end of the branches, white, appearing in July and August.

The ninth contains a variety which is a little more branched, and has smaller shorter leaves: the flowers are paler, the stamens somewhat longer, the anthers smaller and brown; whereas in the larger sort they are violet: and another with variegated leaves.

Method of Culture.—All the herbaceous and ligneous kinds may be readily increased by parting the roots, by slips of the young branches, and seeds: the roots may be divided in the autumn, or early spring, and the slips of the branches be taken off in the spring and summer, being planted out in moist shady situations, and well rooted, they may be removed to where they are to remain, though it is best to plant them at once where they are to grow: the seeds may be sown in a bed or border of common earth in the early spring season.

But in the polium kinds, the seeds should be sown in a bed of light earth, and the plants be either put out in nursery-

rows, or set where they are to remain, in the latter end of summer.

The shrubby sorts may likewise be increased by slips or cuttings of the young shoots of the branches, which should be planted in pots filled with light mould, in the spring and summer months, in order to be removed under the protection of the greenhouse in winter, being afterwards managed as other greenhouse exotics.

These plants are all of the perennial kind, and some of them are durable in the stems and branches for several years.

The first sorts afford variety in the borders, &c. and the latter in assemblage with greenhouse plants.

TEUDERIUM, in *Ancient Geography*, a town of Germany, in the vicinity of Bogadium and Mediolanium. Ptolemy.

TEVENDEZ, in *Geography*, a mountain in the S.E. part of Fez; being part of the Atlas.

TEVERONE, a river of Italy, which joins the Tiber near Rome.

TEVESAR, a town on the W. coast of the island of Celebes. S. lat. 2° 2'. E. long. 119° 21'.

TEUFFEL'S BRUCK, or *Devil's Bridge*, a bridge over the Reufs, formed of a single arch, about twenty-two feet radius, supported by two rocky peaks, nearly perpendicular, between which the river runs at the depth of some hundred feet; 3 miles from Urferen.

TEUFFEN, a town of Switzerland, in the canton of Appenzel; 6 miles N.W. of Appenzel.

TEUFING, or TAUZIM, a town of Bohemia, in the circle of Pilsen; 22 miles N.W. of Pilsen. N. lat. 50° 2'. E. long. 13° 5'.

TEUGA, in *Botany*, the name given in the Hortus Malabaricus to a genus of plants, called by Linnæus and others *coccus*.

TEUGLASSA, in *Ancient Geography*, an island which Thucydides seems to place on the coast of Asia Minor, in the neighbourhood of the Doride.

TEVIN, in *Geography*, a town of Persian Armenia, on a small river which runs into the Aras; 15 miles S.E. of Erivan.

TEUKE, a town of Persia, in the province of Kho-rassan; 32 miles E. of Tabas-kileki.

TEUMES, in *Ancient Geography*, a river of Greece, in Bœotia, which watered the town of Thebes, according to Hefychius.

TEUMESSUS, a borough of Bœotia, upon a mountain E. of Thebes, and near a small river called Thermodon. Here was a temple of Diana Telchinia. It was notorious for the superstitious credulity of its inhabitants.—Also, a mountain of Greece, in Bœotia.

TEVO, ZACCARIA, in *Biography*, author of an ample treatise on music, written in Italian, and published at Venice, in small quarto, 1706, entitled “*Il Musico Testore*,” (*testore* literally means a weaver; but metaphorically, a composer, an author;) the musician's *text*, or guide. The work is divided into four parts, twenty chapters in each, the titles of which are very promising; but his style is not very pleasant, nor are his definitions or instructions very satisfactory. The author had read much, but his digestion was not so good as his appetite. He swallowed, without due mastication, all the old stories about the invention and miraculous powers of music. He assigns to Orpheus, the son of Apollo, the invention of the violin, and to Sappho that of the bow; assuring us that she was the first who used it in the present manner! He not only finds the inventor of every

species of instrument, but the time when and place where it was first constructed. There is little science, and still less ingenuity, in the examples of composition given in illustration of the rules of counterpoint: so that if the young student, who peruses this work for instruction, is not a con-jurer before he begins the task, he will not be made one by the mysteries which it unfolds.

Yet with patient perseverance, a young student who has little leisure, and few books to read, may become superficially learned with little trouble by this book. Tevo quotes authority for all that he advances; but his authorities are not always good, nor does he distinguish good from bad. Several obscure and even contemptible authors are quoted in the same solemn manner as the best. But in citing so many writers indiscriminately, the chief part are now so scarce and difficult to be found, that in search of them all the great libraries of Europe may be visited in vain: To save the student's time, and form his taste in literature, as well as judgment in music, the author should have quoted none but writers of the first authority, or have told his young readers what stress was to be laid on the rest.

But since the time of Tevo, so many better authorities in composition and didactic works, both on the theory and practice of music, have appeared, that we can hardly recommend the "Musico Testore" to the perusal of any but those who have much time to spare, who read every thing, and are curious to know the history and state of the art at every period of time.

TEUOCHIS, in *Ancient Geography*, a lake and town of Egypt.

TEVOEN-SOUSON, in *Geography*, a town of Chinese Tartary; 12 miles N.W. of Teldom.

TEUPITZ, a town of Brandenburg, in the Middle Mark, on a lake; 20 miles S. of Berlin. N. lat. $52^{\circ} 5'$. E. long. $13^{\circ} 30'$.

TEURERT, or TEVRERT, a town of Fez, on the borders of Algiers; 40 miles E.N.E. of Teza. N. lat. $34^{\circ} 2'$. W. long. $3^{\circ} 30'$.

TEURISCI, in *Ancient Geography*, a people placed by Ptolemy in the northern part of Dacia, between the Anerti and the Cistoboci.

TEURISTÆ, a people of Germany, placed by Strabo in the vicinity of the Danube and the Alps.

TEURNIA, a town of Norica, S. of the Danube, between Virunum and Idunum. Ptol. and Plin.

TEURTEVILLE, in *Geography*, a town of France, in the department of the Channel; 6 miles N. of Valognes.

TEUSCHNITZ, a town of Bavaria, in the bishopric of Bamberg; 34 miles N.E. of Bamberg. N. lat. $50^{\circ} 23'$. E. long. $11^{\circ} 30'$.

TEUSHANUSHSOUGGOGHTA, an Indian town of Pennsylvania, on the Alleghany river.

TEUTATES, in *Mythology*, a name or attribute of the Supreme Being, which was worshipped by the Gauls and Britons as a particular divinity. It is evidently compounded of the two British words "Deu-tatt," which signify God the parent or creator, a name properly due only to the one true God, who was originally intended by that name. Thus Lucan, l. i. v. 445.

"Et quibus immitis placetur fanguine divo
Teutates; horranique feris altaribus Hesus."

When these ancient nations sunk into idolatry, they degraded Teutates into the sovereign of the infernal world, the same with the Dis and Pluto of the Greeks and Romans (or, as others think, with Mercury); and worshipped

him in such a manner as could be agreeable to none but an infernal power.

TEUTHEA, in *Ancient Geography*, a considerable town of the Peloponnesus, in Achaia, W. of Tritæa.

TEUTHIS, a town of the Peloponnesus, in Arcadia, in which were a temple of Venus, and another of Diana.

TEUTHIS, in the Linnæan system of *Ichthyology*, a genus of the abdominal fishes; the characters of which are, that the head is a little truncated on the fore-part; that the branchiostege membrane has five rays; and that the teeth are equal, rigid, and near each other, and forming a regular chain. Linnæus and Gmelin mention two species; viz. *hepatus*, and *javus* or *java*. This genus is now annulled, and the species are transferred to *Acanthurus* and *Chætodon*.

HEPATUS; *Acanthurus* Teuthis; Blue *Acanthurus*. With the middle of the body paler, and a spine on each side of the tail. This is a native of the Indian and American seas, ten or twelve inches long, or more; resembling in shape the chætodons, the head sloping in front from the origin of the dorsal fin; the colour, when recent, a deep or blackish-blue; on each side of the body is a very large, oblong-ovate whitish patch or spot, surrounded by a border of a deeper cast; the skin is roughened by very small scales; the tail is slightly lunated, dusky on the upper and lower part, and marked towards the base by a whitish ovate spot; the teeth are crenated; and on each side of the base of the tail is a very strong spine, capable of elevation at the animal's pleasure, to an horizontal direction, from the channel in which it lies. The fish figured by Catesby in his *Natural History of Carolina*, under the name of *Teng*, is supposed to be this species.

JAVA or JAVUS; *Chætodon* Guttatus. Whitish-grey, with oblong body, sprinkled with very numerous, round, rufous spots; length about ten or twelve inches; colour grey, with a dusky tinge on the upper parts, and every where sprinkled, except on the head, pectoral, ventral, dorsal and anal fins, with numerous, small, round, rufous spots; scales small, none at the bases of the fins; gill-covers smooth; dorsal and anal fin of moderate breadth; tail slightly inclining to a forked, or rather lunated shape, and speckled like the body. Native of Java. This species is supposed by Bloch and Cope to be the *teuthis javus* of Linnæus. But Dr. Shaw remarks, that Linnæus's description does not agree in the disposition of its colours with those of the *C. guttatus*, as it is expressly said to be marked with longitudinal streaks: so it is figured by Gronovius. See *CHÆTODON Guttatus*, changing Japan in the close of that article to Java.

TEUTHOPHACE, a word used by the ancients to express a sort of food made of beet-roots and lentils, often prescribed as a good diet for the sick.

TEUTHRANIA, in *Ancient Geography*, a town and small country of Mysia, situated towards the E., and near the source of the Caicus. Herodotus says that it was once a gulf, and it was gradually formed by the accumulation occasioned by the Caicus.

TEUTHRONA, a town of Laconia, in a small bay, on the Laconic gulf, N.E. of Pyrrhius.

TEUTLAN, in *Geography*, a town of Mexico, in the province of Guadaluja; 50 miles N.N.W. of Guadaluja.

TEUTLEBEN, a town of Germany, in the principality of Götha; 4 miles W. of Götha.

TEUTONES, in *Ancient Geography*, a people of Germany, who at the time when the Romans became acquainted with them, were politically connected with the Cimbri; they

they were not actually a tribe of the same people; and settled at no great distance from them. (See CIMBRI.) They are said to have worshipped a divinity called *Thaut*, who is supposed to have been one of their ancestors deified. The Teutones were known before the Cimbri, and uniting with them, overran the territories that were subject to the Romans; and it has been affirmed that they inhabited the banks of the *Codani Sinus*, and the island called *Codania Insula*, whence they assumed the appellation of "Codani." Pytheas of Marseilles, according to Pliny, is the first author who mentions the Teutones; and Pomponius Mela says, that their habitations were near the gulf *Codanus*. It is very probable that they extended themselves through the country that bordered on the Baltic sea; and that from thence they engaged in many warlike emigrations; transporting themselves with their arms and baggage, their wives and children, through other countries which they pillaged. It was in the year of Rome 640 that they first became known to the Romans; having advanced south of the Danube to the country called Noricum, where they were encountered by the consul C. Papirius Cursor, who obstructed their passage towards the borders of Italy. They then proceeded towards Gaul, and made their ingress among the Helvetians. Having arrived in Gallia Narbonensis, the Cimbri were there defeated by the consul Aurelius; but the Teutones made an attempt to invade Italy by the Western Alps. They were, however, resisted by Marius, and in a desperate engagement, in which the latter proved victorious, the Teutones left upon the field an almost incredible number of slain; which, including the Gauls who had fallen in a combat which took place some days before, amounted, according to historians that have not been chargeable with exaggeration, to 100,000 persons. Marius also defeated the Cimbri in Italy.

TEUTONIC, something belonging to the *Teutones*, an ancient people of Germany, inhabiting chiefly along the coast of the German ocean. See GOTHIC.

TEUTONIC *Language*, is the ancient language of Germany, which is ranked among the mother-tongues.

The Teutonic is now called the *German*, or *Dutch*, and is distinguished into *upper* and *lower*.

The *upper* has two notable dialects; *viz.* 1. The Scandinavian, Danish, or perhaps Gothic; to which belong the languages spoken in Denmark, Norway, Sweden, and Iceland. 2. The Saxon, to which belong the several languages of the English, Scots, Frisian, and those on the north of the Elbe.

To the *lower* belong the Low Dutch, Flemish, &c. spoken through the Netherlands, &c.

The learned Mr. Whitaker has lately, in his *History of Manchester*, controverted the opinion of those who affirm the English language to be genuine and unmixed Teutonic, and asserted it to be of Celtic origin. Mr. Drake, in his *Essay on the Origin of the English Language*, Archæol. vol. 5. has endeavoured to support the former opinion, by comparing part of Ulphila's Gothic version of the gospel of St. John, executed above 1400 years ago, with the same in our present translation, and evincing the striking affinity between the two languages; notwithstanding the different mediums through which they have descended, and the many ages that have elapsed since they have been separated. Every circumstance, he observes, that constitutes the true genius of a language, is visibly derived to the English from the Goths and Saxons. The articles, flexure of the genitive case, prepositions and auxiliary verbs, are all absolutely Teutonic. The English, he says, is clearly the natural descendant of the Gothic or Teutonic; and he challenges the deepest enquirer into the Celtic to produce so decisive a proof of

any affinity of that tongue with ours. The British, he adds, has little or no resemblance to the English. Many of their terms may have gained admission among us, as, from the vicinity and long intercourse we have had with that people, may necessarily be imagined, but their idioms and genius are as radically and essentially different as any two languages can possibly be.

TEUTONIC *Order*, a military religious order of knights, established towards the close of the twelfth century; and thus called, because it consisted principally of Germans, or Teutones.

The origin, &c. of this order were thus: the Christians, under Guy of Lusignan, laying siege to Acre, or Acon, a city of Syria, on the borders of the Holy Land; at which siege were present, Richard king of England, Philip Augustus of France, &c. some Germans of Bremen and Lubec, touched with compassion for the sick and wounded of the army, who wanted common necessaries, set on foot a kind of hospital under a tent, which they made of a ship's sail; and here betook themselves to a charitable attendance on them.

This started a thought (about the year 1190) of establishing a third military order, in imitation of the Templars, and the Hospitalers.

The design was approved by the patriarch of Jerusalem, the archbishops and bishops of the neighbouring places, the king of Jerusalem, the masters of the Temple and the Hospital, and the German lords and prelates then in the Holy Land; and, by common consent, Frederic duke of Suabia, who was then at their head, sent ambassadors to his brother Henry, king of the Romans, to solicit the pope to confirm the new order.

Calixtus III. who then governed the church, granted it by a bull of the 23d of February, 1192, and the new order was called "The Order of Teutonic Knights of the House of St. Mary of Jerusalem."

The habit of this order was a white mantle, with a black cross.

The pope granted them all the privileges of the Templars, and the Hospitalers of St. John; excepting that they were to be subject to the patriarchs, and other prelates; and that they should pay tithe of what they possessed.

The first master of the Teutonic order, Henry Walpot, elected during the time of the siege of Acre, after the taking of that city, purchased a garden, in which he built a church, and an hospital, which was the first house of the Teutonic order.

Such is the account given by Peter of Duisbourg, a priest of this order.

Jaques de Vitty differs a little from this account; and relates, that the Teutonic order was established at Jerusalem before the city of Acre was besieged.

The order made no great progress under the three first grand-masters; but under the fourth, Herman de Salza, it became very powerful; inasmuch that Conrad, duke of Mazovia and Cujavia, about the year 1230, sent an embassy to him, to solicit his friendship and assistance, offering him and his order the provinces of Culme and Livonia, with all the lands they could recover from the idolatrous Prussians, who harassed him exceedingly with their continual incursions, and against whom he intended this new militia; his own knights of the order of Christ, or of Dobrin, instituted for the like purpose, being found too weak.

De Salza accepted the donation, and Gregory IX. confirmed it; and, to aid the knights in reducing the Prussians,

fians, Innocent IV. published a croifade. With this help, in a year's time, they fubdued the provinces of Warmia, Natangia, and Barthia; the inhabitants of which renounced the worfhip of idols; and, in the courfe of fifty years more, they reduced all Pruffia, Livonia, Samogitia, and Pomerania, &c.

In 1204, duke Albert had founded the order of Sword-bearers, Port-glaives, which now became united to the Teutonic knights, and the union was approved by pope Gregory IX.

The order, thus mafters of all Pruffia, built the cities of Elbing, Marienburg, Thorn, Dantzick, Koningfberg, and fome others: the emperor Frederic II. permitted them to add to the arms of their order, the imperial eagle; and St. Louis, in 1250, allowed them to quarter the fleur-de-lis.

After the city of Acre had been recovered by the infidels, the grand-mafter of the Teutonic order removed his feat from that city to Marienburg. As the order grew in power, the knights took more ftate on them; and at length, inftead of friars, brothers, as at firft, would be called *lords*. And though the grand-mafter Conrade Zolnera, of Rotenfteine, oppofed this innovation, his fucceffor Conrade Wallerod not only approved it, but even procured himfelf to be treated with honours only rendered to the greateft princes.

Divifions being got into the order, the kings of Poland made their advantage of them: the Pruffians revolted to them: and after feveral wars between the knights and the Poles, the former yielded to king Cafimir the Upper Pruffia, and did homage to him for the Lower.

At the time of the Reformation, Albert, marquis of Brandenburg, then grand-mafter, becoming a Lutheran, renounced the dignity of grand-mafter, diffolved the commanderies, and drove the knights out of Pruffia.

Moft of the knights followed his example, and embraced the reformation: the reft transferred the feat of their order to Margentheim, or Mariendahl, in Franconia, which they ftill retain.

They there elected Walter of Cromberg their grand-mafter, formed a procefs againft Albert, and the emperor put him to the ban of the empire. The order, however, could never recover their domains; and are now little more than the fhadow of what they formerly were, having only three or four commanderies, fcarcely fufficient for the ordinary fubfiftence of the grand-mafter and his knights.

The officers of the Teutonic order, when in its fplendor, were the grand-mafter, who refided at Marienburg: under him were the grand-commander; the grand-marfhal, who had his refidence at Koningfberg; the grand-hofpitaler, who refided at Elbing; the draper, who took care to furnifh the habits; the treafurer, who lived at the court of the grand-mafter; and feveral commanders, as thofe of Thorne, Culme, Brandenburg, Koningfberg, Elbing, &c.

They had alfo their commanders of particular caftles and fortrefles; advocates, proveditors, intendants of mills, provifions, &c.

Waiffelius, in his Annals, fays they had twenty-eight commanders of cities, forty-fix of caftles, eighty-one hofpitalers, thirty-five mafters of convents, forty ftewards, thirty-feven proveditors, ninety-three mafters of mills, feven hundred brothers or knights to take the field, one hundred and fixty-two brothers of the choir, or priefts, and fix thoufand two hundred fervitors or domeftics.

TEUTSCH LEIPSH, in *Geography*, a town of Hungary 5 miles E. of Rozenberg.

TEUTSCH Pron, a town of Hungary; 10 miles N.W. of Krennitz.

TEUTSCHDORF, a town of Hungary; 5 miles N.W. of Cafchau.

TEUTSDORF, a town of Pruffia, in the province of Oberland; 10 miles E.N.E. of Holland.

TEUVRENT, a town of Africa; 145 miles E.N.E. of Fez.

TEUW, a fmall ifland in the Eaft Indian fea. S. lat. 7° 11'. E. long. 129° 20'.

TEUXUNTA, in *Ancient Geography*, a town of Sicily, which had been built by Micythus, king of Rhegium and Zancle, according to Diodorus Siculus.

TEWANTAPAGUE, in *Geography*, a town of Mexico, in the province of Guaxaca; 135 miles E.S.E. of Guaxaca.

TEWKESBURY, anciently *Teodecheberie*, a large and refpectable borough and market-town, in the lower divifion of the hundred of the fame name, in Gloucefterfhire, England, is fituated in the vale of Evesham, on the eaftern banks of the Avon, near its confluence with the Severn, at the diftance of 8 miles N.N.E. from Gloucefter, and 104 miles W.N.W. from London. This town was rendered famous in hiftory, from a battle fought near it, between the Yorkifts and Lancaftrians; wherein Edward IV. gave a total overthrow to Henry VI. Three thoufand of the Lancaftrians were reported to have been flain in the field, and queen Margaret, with many others, was taken prifoner. The feveral circumftances which occurred during the engagement, and the events fubfequent to the victory, are very fully related in the hiftories of England. Tewkesbury was again the fcene of another action in the civil wars of Charles I. It was at different periods in poffeffion of both parties; and the final capture of it by the parliamentary forces was of great confequence as a frontier town, fecuring that fide of the county, and commanding great part of Worcefterfhire.

Tewkesbury was firft incorporated by charter in the 17th of Elizabeth, under the title of "bailiffs, burgefles, and community of the borough of Tewkesbury." Other charters were granted by James I. and James II.; the latter, in the fecond year of his reign, re-incorporated them by the name of "mayor, aldermen, and common council;" but this charter was not acted upon: and the government of the town, as a corporation, was dormant till 13 William III. when the prefent charter was obtained, under which the town is governed by twenty-four principal burgefles, who, with twenty-four affiftants, act independent of the magiftrates of the county. From thefe are annually elected two bailiffs and four juftices, who, with the recorder, form the magiftracy of the corporation. The privilege of fending members to parliament was firft obtained 7 James I. The right of elecfion is in the freemen and freeholders within the borough: the latter of whom have a vote generally for the county. The number of voters amount to about 500, and the bailiffs are the returning officers. The principal manufacture for the employment of the inhabitants is ftocking-frame work knitting, particularly cotton. This fupplies work for the Houfe of Induftry, which is a modern building, well adapted for the purpofe of rendering the poor cleanly, moral, and induftrious. The markets, which were eftablifhed as early as the Conqueit, are held on Wednesday and Saturday: and here are feven annual fairs. The town-hall, which is a handfome edifice, was erected by fir William Codrington in 1788, at an expence of 1200*l.* The ground-floor is appropriated for holding

holding the quarter-fessions; the upper floor for a banquetting room, and for the meeting of the corporation. Among the charitable establishments are a free grammar-school, a charity-school, and several alms-houses. The Anabaptists, Quakers, Independents, and Methodists, have each a meeting-house in the town. The population, according to the returns of the year 1811, amounted to 4820; the number of houses being 1003: the latter are chiefly of brick, and principally ranged in three spacious streets. Since the year 1786, when an act was passed for paving and lighting the town, many improvements have been made; and the buildings have assumed an air of respectability.

The Abbey.—A monastery was first erected here, and endowed by two brothers, Oddo and Doddo, dukes of Mercia, A.D. 715, to the honour of the Blessed Virgin, which having undergone many calamities during the civil and Danish wars, about 980 became a priory, subject to Cranbourn in Dorsetshire: but Robert Fitzhamon, a noble Norman, who came to England with the Conqueror, enlarged the buildings and increased the possessions of Tewkesbury so much, that the monks of Cranbourn chose, about 1102, to remove to this place, leaving only a prior and two monks behind, and made Cranbourn in future subject to the abbey of Tewkesbury. From this time it became a great establishment of Benedictine monks; and at the suppression, the annual revenues amounted to 1598*l.* 1*s.* 3*d.*, exclusive of 136*l.* 8*s.* 1*d.* granted by the convent for fees and annuities: its plate also was very valuable, the sacristy alone containing 1421 ounces. After the dissolution, the destruction of the monastic buildings was rapid and complete, through the ineffectual opposition of the monks to the visitors appointed by the king, who, in revenge, destroyed the Lady chapel, cloisters, chapter-house, and other appendages by fire. The remains of the buildings were afterwards purchased by the inhabitants: and the Abbey Church was made parochial. This magnificent structure displays an interesting example of early Norman architecture, combined with specimens of later styles, and is in other respects well calculated to arrest the attention of the antiquary. It is built in the cathedral form, and consists of a nave, choir, transept, and central tower, with the addition of several chapels, ranged round the aisle of the choir. The nave and choir are separated from the aisles by eighteen massive columns, sustaining the roof, and four substantial piers which support the tower. At the west end is a large window with a pointed arch, which appears to have been introduced within a semicircular arch in 1656. There were cloisters on the south side of the nave, where some fragments yet remain; and appear to have been highly ornamented in a similar style to those at Gloucester. The tower, according to the Abbey chronicles, was once terminated by a wooden spire, which fell down on Easter-day, 1559. The most remarkable specimens of the architecture are three tiers of arcades in the upper part; the arches of the middle tier have interesting mouldings. The length of the church is 300 feet; of the transept 120; the breadth of the choir and side-aisles is 70 feet; of the west front 100; the height from the area to the roof is 120 feet; the height of the tower 152 feet. The monuments, which are numerous, have attracted the attention of various antiquaries, particularly Mr. Gough and Mr. Lysons; the latter of whom has taken great pains in aligning the different tombs to the real persons they were intended to commemorate: many mistakes, in this respect, having been committed on traditional authority

by former writers. Near the west end of the church is the Abbey Gate-house, which appears of the age of the fifteenth century: it is embattled and ornamented with grotesque figures, projecting from a cornice; beneath which is a canopied niche between two square windows.—Dyde's History, &c. of Tewkesbury, 8vo. 1798. Rudge's History of Gloucestershire, vol. i. 1803. Beauties of England and Wales, vol. v. Gloucestershire; by J. Britton and E. W. Brayley.

T EWKESBURY, called *Wamefit*, or *Parwtucket*, by the Indians, a township of Massachusetts, in the county of Middlesex, containing 943 inhabitants; 24 miles N. of Boston.

TEXALI, in *Ancient Geography*, the inhabitants of the sea-coasts of Aberdeenshire; who had a town, called Devana, at the mouth of the river Deva (Dee), where old Aberdeen now stands.

TEXAS, in *Geography*, a province of New Spain, which properly forms part of Louisiana. This province is claimed by Spain as part of the internal provinces, and included in the vast intendency of San Louis Potosi: it is bounded E. by the state of Louisiana, S. by the gulf of Mexico, W. by an imaginary limit, and N. by Red river, and contains an area exceeding 100,000 square miles. The capital of this province is the garrison of San Antonio de Bejar, ridiculously called the New Philippines. It was founded in 1731, consisting of a captain, a lieutenant, and one company of soldiers. The station of Ceniz in this province, is now a mere Indian village, with the ruins of a fort built by the French. That called Natchitoches, from an Indian tribe, friends of the French and enemies of the Spaniards, was a small fort, built on an island of the Red river by some French veterans. But the station of Adayes, or Adayes, is regarded by the Spanish writers as the extreme fortrefs in this quarter: it is seated in a fertile country, at the distance of two leagues from a lake of the same name, which abounds in fish, and which in some parts is five leagues in diameter, and probably ten in circumference, with a gulf which may be navigated by large vessels. In the middle of the lake is a hill, or rock, of a pyramidal form, more than 100 yards in circumference, the stone of which resembles crystal in its reflection of the solar rays, and it is the highest in the district. The vicinity abounds in wild cattle, bears and beavers; and the soil is fertile in maize and other grain. Pinkerton.

TEXEIRA, JOSEPH (PETER), in *Biography*, a Portuguese historian, was born in 1543, entered among the Dominicans, and became prior of the monastery at Santarem in 1578. When Philip II. of Spain took possession of Portugal, Texeira attached himself to Don Antonio, who had been proclaimed king by the Portuguese, and accompanied him into France. In 1582 he was taken prisoner by the Spaniards, but made his escape from Lisbon. He became confessor to Don Antonio, and, in process of time, preacher and almoner to the French king Henry III. He afterwards attached himself to Henry IV., and in 1596 assisted at the abjuration of Calvinism by the princefs of Condé. He was sent on one mission to England, and favourably received by king James. He died at Paris in 1604, as some say; but according to another account, in 1620.

In 1582, Texeira printed his "Compendium de Portugalliz ortu Regni initii, &c." This work was answered by order of the king of Spain; and Texeira replied, in 1592, by a "Confutatio, &c." which professed to refute the hereditary right of Philip to the crown of Portugal, and to vindicate that of Don Antonio;—probably the same work that is entitled "De Electionis Jure quod competit Viris Portugallensibus inaugurandis suis Regibus," Lyons, 1589.

As a genealogist, under which character he was distinguished, he published in 1590, "Exegetis Genealogica Arboris Gentilitiæ Henrici IV., Gallorum Regis," enlarged in 1598, with the addition of the prince's of Condé's abjuration. In token of the indignation he felt at the seizure of his country by Philip, he affirmed, as it is said, in one of his sermons, that "we were bound to love all men, of whatever religion, sect or nation, even if they were Castilians." Bayle. Moreri.

TEXEL, or TESSEL, in *Geography*, an island of Holland, about 11 miles in length, and six in its greatest breadth; situated at the mouth of the Zuyder See, with a capacious and good harbour, and a fort, which commands the entrance; besides a town of the same name, it contains six villages: the land is fertile in pasture, and the whole well secured with dikes of prodigious strength and height. Near this island was the celebrated sea-fight, between the fleet of Holland, under admiral Martin Harpertz Tromp, and that of England, under admiral Blake, in the year 1653, in which Tromp was killed. In the year 1673 a battle was fought between the fleet of Holland and the united fleets of England and France, in which the victory was doubtful. N. lat. 53° 5'. E. long. 4° 40'.

TEXEUIT, or TEYENT, a town of Morocco; 100 miles W.N.W. of Morocco.

TEXT, a relative term, contradistinguished to *gloss* or *commentary*; and signifying an original discourse, exclusive of any note or interpretation.

Infinite pains have been taken by the critics, to restore, reconcile, settle, explain, &c. the text of the bible, and that of the classics. See BIBLE.

Mr. Whiston accounts for all those misunderstandings between the Old and New Testament, particularly as to the prophecies in the Old, cited as fulfilled in the New, from the corruption of the text of the Old Testament; and to obviate objections made against Christianity on that head, has published an "Essay towards restoring the true Text of the Old Testament." See PROPHECY.

This restoration he attempts to effect from the Samaritan Pentateuch, the Roman Psalter, the Apostolical Constitutions, &c.

It sufficiently appears from the learned and acceptable labours of the late Dr. Kennicott, in collating the Hebrew manuscripts of the Old Testament, that the alterations introduced into the text, &c. are mostly of a trivial nature, and by no means affect the authority of the sacred writings.

TEXT is particularly used for a certain passage of scripture chosen by a preacher, to be the subject of his sermon.

A collection of texts appropriate to different subjects, and judiciously arranged, has been published by Dr. Enfield for the use of preachers in the composition of their discourses, and also of biblical readers and students.

Anciently, the lawyers began all their pleadings with like texts of scripture.

A text-book, in several universities, is a classic author written very wide, by the students, to give room for an interpretation dictated by the master or regent, to be inserted in the interlines.

In this sense, the French say, proverbially, *Glose d'Orléans plus obscure que le texte*.

The Spaniards gave the name text to a kind of little poem, or set of verses placed at the head of a gloss, and making the subject of it: each verse being explained, one after another, in the course of the gloss.

TEXT, in *Ancient Law Authors*, is appropriated to the

book of the Four Gospels, by way of eminence. These were written in gold letters, and carefully preserved in the churches.

"Codex aurato confectus grammate scriptus.
Auctus evangelicum conservat corpore textum."

TEXTUARIES, TEXTUARI, a name given to the sect of the Caraites, among the Jews.

Hillel shone among the traditionaries, and Schammai among the textuaries.

The civil and canon lawyers sometimes also call a book containing the bare text, without any gloss or commentary, a textuary, *textuarium*.

TEXTURE, TEXTURA, formed of *texo*, *I weave*, properly denotes the arrangement and cohesion of several slender bodies or threads, interwoven or entangled among each other: as in the webs of spiders, or in cloths, stuffs, &c.

TEXTURE is also used in speaking of any union or cohesion of the constituent particles of a concrete body; whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way.

In this sense, we say a close, compact texture; a lax, porous texture; a regular or irregular texture, &c.

A great deal depends on the texture of the component parts of a body: hence most of its particular properties, its specific gravity, colour, &c.

TEXTUS ROFFENSIS, is an ancient manuscript, containing the rights, customs, tenures, &c. of the church of Rochester, granted by the laws of Ethelbert, Hlothhere, Eadred, and Withred, kings of Kent, collected by Er-nulf, the venerable bishop of Rochester, about the year 1100.

TEYA, in *Geography*, a river of Austria, which rises about three miles N. from Germs, passes through a part of Moravia, and runs into the March, 11 miles N.E. of Zisterdorf.

TEYN, a town of Bohemia, in the circle of Boleflau; 12 miles W.N.W. of Jung Buntzel.

TE-YUEN, a town of Asia, in the kingdom of Corea; 93 miles N.E. of King-ki-tao.

TEZA, a town of Africa, in the kingdom of Fez, with a castle. It was once a populous city, but is now much decayed, yet is still the residence of a governor and a garrison; 20 leagues N.N.E. of Fez.

TEZCUCO, or TETZCUCO, a lake of Spanish America, in the province of Mexico. The conjunct lakes of Tezcuco and Chalco are found to be about 30 British miles in length, and the former is about 15 miles in breadth; but as the latter is partly drained, so as to be at the distance of a league from the city, it is probably about twelve miles in breadth. This lake is celebrated in history, as originally containing the city of Mexico, and also as remarkable for the qualities of the water, partly fresh, and partly saline. The Chalco, or fresh-water lake in the south, appears to flow by a narrow channel into the salt lake of Tezcuco. See MEXICO, substituting for Tezeuco, *Tezcuco*.

TEZELA, a town of Africa, in the kingdom of Algiers; 5 leagues S.W. of Oran.

TEZERGBE, a town of Africa, in the kingdom of Fez; 100 miles E.S.E. of Teza.

TEZOUT, or TESSOT, a town of Africa, in the kingdom of Fez; 35 miles S. of Melilla.

TFENI, a town of Egypt, on the Nile; 10 miles S.E. of Rosetta.

TFUOI, in the *Chinese Manufactory of Porcelain*, a word used to express a particular sort of varnish for that ware,

with violet-colour and gold. The usual method of doing this at first, was by mixing gold with the common varnish, breaking the leaves very small, and then adding the common blue and the powder of calcined agate of a coarse kind, found in great plenty on the shores of their rivers. But they have since found that the brown varnish called *tschin* succeeds much better, for when the blue is mixed with this, its brown colour is lost, and the gold lies on much better than it would any other way.

They had once a method of a varied varnish, which was very beautiful, but is much neglected now; this was the giving a vessel the brown varnish on the outside with a large portion of gold, and the common white varnish within. They also varied the degree of colour on the outside, by laying on more or less of the varnish; and gave this way a variety, even in the same colour. *Observ. sur les Cōtumes de l'Asie*, p. 308.

TGIDT, in *Geography*, a town of Arabia, in the province of Oman; 48 miles N. of Fartach.

THABBA, in *Ancient Geography*, a town of Arabia Felix, situated between Menambis and Seba, now *Ebba*. Ptol.—Also, an ancient town of Africa, in the vicinity of Tichafa.

THABET EBN KORRA, in *Biography*. See THEBIT BEN CORAH.

THABILIACA, in *Ancient Geography*, a town of Albania, between the rivers Gerrus and Soanes. Ptol.

THABIR, in *Geography*, a mountain of Arabia; 20 miles S. of Medina.

THABOR, in *Ancient Geography*. See TABOR.

THABORITES. See TABORITES.

THABRACA COLONIA, *Tabarka*, in *Ancient Geography*, a town and Roman colony of Africa, in Numidia, according to Ptolemy. It was situated on the western bank, and near the mouth of the river Tufca. Some vestiges remain of walls and cisterns.

THABUCA, a town of Spain, in the interior of the Tarragonensis, belonging to the Varduli. Ptol.

THACAS, *ῥακας*, in *Antiquity*, a general name given to the place or feat where the augurs made their observations.

THACCONA, in *Ancient Geography*, a town of Asia, in Babylonia, upon an arm of the Euphrates. Ptol.

THACES, a people of Scythia, on this side of the Imaus, and near it. Ptol.

THACK TYLES. See TYLE.

THÆMA, in *Ancient Geography*, a town in the interior of Arabia Deserta. Ptol.

THÆNA, or THËNÆ, a town placed by Strabo, Pliny, and Ptolemy, on the coast of Africa, towards the commencement of the Lesser Syrtes.—Also, a town of Asia, in Syria, situated, according to Ptolemy, in Cyrrhestica.

THAGIA, in *Geography*, a town of Africa; 100 miles S.S.W. of Fez.

THAGORA, TINGORAN, in *Ancient Geography*, a post of India, at the bottom of a small gulf, in the eastern part of the peninsula, beyond the Ganges.

THAGULIS, a town of Africa, situated between the Two Syrtes. Ptol.

THAHAR KIAMEN, in *Geography*, a post of Chinese Tartary; 15 miles N.E. of Teiticar.

THAHATH, in *Ancient Geography*, the place of the 23d station of the Israelites, where they encamped, after having left Mauloth; situated in the desert of Arabia, S. of Mauloth.

THAINEE, in *Geography*, a town of Africa, in the kingdom of Tunis, near the east coast, but without a harbour, at a small distance from the mouth of a river of the same name; 120 miles S. of Tunis.

THAIS, a town of France, in the department of Paris; 2 leagues S.S.E. of Paris.

THAIS, a name given by Ægineta to a cosmetic cerate, intended to give a beautiful red to the face. Galen uses the same word to express a sort of bandage.

THALA, *Ferre Anach*, in *Ancient Geography*, a town of Africa, in Numidia, according to Sallust and Tacitus.—Also, a mountain of Africa, in Interior Libya, and the people inhabiting its vicinity were called Thalæ.

THALACH, in *Geography*, a river of Bavaria, which runs into the Schwarzach; 5 miles W. of Greding.

THALAMEGUS, among the *Ancients*, a ship of pleasure, or yacht used by princes. It was always provided with a good cabin, or bed-chamber. See SHIP.

THALAMI *Nervorum Opticorum*, in *Anatomy*, two eminences in the brain. See BRAIN.

THALAMIA, in *Botany*, see LICHENES, one of whose kinds of *Apothecium*, or receptacle, is so denominated by Acharius.

THALAMII, among the *Ancients*, those rowers who sat in the lowest part of the ship. See the next article.

THALAMITÆ, in the *Naval Architecture of the Ancients*, a term used to express those rowers in the polycrote galleys, or those who contained several series of rowers, who sat on the thalamus of the vessel, and made the lowest row. These moved their oars and hands under the seats of the row that sat next above them. See POLYCROTA.

THALAMIUM, among the *Ancients*, a port-hole, through which the oars of the rowers in the bottom of the ship went.

THALAMUS, in *Botany*, a term used to express that part of the flower in the capitated or flosculous-flowered plants, where the embryo fruits of every separate floscule are lodged, and where afterwards the seeds are contained. This is the bottom of the cup, in the central part of which it adheres to the stalk.

THALASSAR, in *Ancient Geography*, a province of Asia, between Mesopotamia and Armenia.

THALASSOMELI, the name of a medicine used as a purge among the ancients. It was composed of equal parts of honey, sea-water, and rain-water, exposed to the sun in the dog-days, in a vessel pitched on the inside. It purged in the same manner that sea-water alone would do, but only in a milder way.

THALASSUS, in *Ancient Geography*, a town or port in the southern part of the isle of Crete.

THALATHA, a town of Asia, in Babylonia, on the banks of the Tigris, and S. of Apamea.

THALATTA, a lake or marsh, at the foot of mount Caucasus, in the environs of the people called "Coraxi." It discharged its waters into the Euxine sea, near a place called Beithæa-Ponti.

THALBIS, a river of Albania, between the Gerrus and the Soanes. Ptol.

THALEA, a town of Palestine, in the tribe of Simeon, according to the book of Joshua.

THALER. in *Commerce*. See RIXDOLLAR.

THALES, in *Biography*, the founder of the Ionic school, and of the scientific method of philosophising among the Greeks, was born of Phœnician parents, at Miletus, in the first year of the 35th Olympiad, or about the year 580 B.C. He acquired wealth and distinction among his countrymen, and was employed at an early age in public affairs. He declined involving himself by marriage, in the cares of a family, that he might devote his whole time and attention to the study of philosophy; alleging, as it is said, to his mother, who urged him to marry, at an early age

"it is too soon," and at a more advanced period "it is too late." In order more entirely to disengage himself from every avocation that would divert his mind from his favourite pursuits, he committed the care of his estate to his sister's son, whom he adopted. In search of wisdom, he travelled to Crete, and afterwards to Egypt. From the priests at Memphis in the latter country, he is said by several writers to have gained his knowledge of philosophy and mathematics. But it is more probable that he was more indebted to his own talents and assiduity in the exercise of them, than to any communication from them; and accordingly it has been affirmed, that he taught them how to measure the height of their pyramids. Upon his return to Miletus, he was universally respected for his extraordinary wisdom and learning; and his acquaintance was eagerly courted by all who wished to improve in knowledge or to be ranked among philosophers. He was not prevented, however, by these engagements from prosecuting his mathematical, philosophical, and metaphysical studies. In this course of improvement and usefulness, and of imparting, as well as of acquiring knowledge, he protracted his life to the great age of ninety years, and died, through mere infirmity, whilst he was attending the Olympic games. Thales was ranked among the seven wise men of Greece, and might justly be reckoned one of this number, whether we consider his scientific attainments, or the moral maxims and aphorisms which are ascribed to him. Of these maxims, we shall select the following: "Neither the crimes, nor the thoughts, of bad men are concealed from the gods. Health of body, competent fortune, and a cultivated mind, are the chief sources of happiness. What is the most difficult thing? To know one's self. What the easiest? To give advice to others. How shall we best attain to virtue? By abstaining from all that we blame in others. Parents may expect from their children that obedience which they paid to their own parents. Take more pains to correct the blemishes of the mind, than those of the face. Stop the mouth of slander by prudence. Be careful not to do that yourself, which you blame in another. Friends should be remembered when absent, as well as when present." Laertius. Brucker by Enfield, vol. i. For an account of his philosophical doctrines and other particulars, we refer to the article *IONIC Sect.*

THALETAS of Crete, a famous lyric poet, celebrated by all antiquity as a medical musician, is said to have delivered the Lacedæmonians from the pestilence by the sweetness of his lyre; but credulity in the powers of music must be very strong indeed, in those who could believe it possible for music to drive away the pestilence. Thaletas, however, was universally believed to have possessed this power; but it is impossible to render the fact credible, without qualifying it by several circumstances omitted in the relation. In the first place, it is certain that this poet was received among the Lacedæmonians during the plague, by command of an oracle; that by virtue of this mission, all the poetry of the hymns which he sung, must have consisted of prayers and supplications, in order to avert the anger of the gods against the people, whom he exhorted to sacrifices, expiations, purifications, and many other acts of devotion; which, however superstitious, could not fail to agitate the minds of the multitude, and to produce nearly the same effects as public fasts, and, in Catholic countries, processions, at present, in times of danger, by exalting the courage, and by animating hope.

The disease having, probably, reached its highest pitch of malignity when the musician arrived, must afterwards have become less contagious by degrees; till, at length, ceasing of itself, by the air wafting away the seeds of infec-

tion, and recovering its former purity, the extirpation of the disease was attributed by the people to the music of Thaletas, who had been thought the sole mediator, to whom they owed their happy deliverance.

This is probably what Plutarch means, who tells the story; and what Homer meant, in attributing the cessation of the plague among the Greeks, at the siege of Troy, to music.

"With hymns divine the joyous banquet ends,
The Pæans lengthen'd till the sun descends:
The Greeks restor'd, the grateful notes prolong;
Apollo listens, and approves the song."

Pope's Homer's Iliad, book i.

For the poet, in this passage, seems only to say, that Apollo was rendered favourable, and had delivered the Greeks from the scourge with which they were attacked, in consequence of Chryseis having been restored to her father, and of sacrifices and offerings.

This poet-musician has been confounded by some writers with Thales the celebrated Milesian philosopher; but according to Plutarch (in Lycurg.) he was cotemporary with Lycurgus the Spartan legislator, and lived about three hundred years after the Trojan war. Plutarch also informs us, that though Thaletas was only styled a lyric poet and musician, he was likewise a great philosopher and politician; inasmuch that Lycurgus brought him from Crete, when he returned from his travels, to Sparta, in order to have assistance from him, in establishing his new form of government. His odes, continues Plutarch, were so many exhortations to obedience and concord, which he enforced by the sweetness of his voice and melody. Plato, likewise, describes his captivating manner of singing; and Plutarch, in his Dialogue on Music, ascribes to Thaletas many musical compositions and inventions: such as Pæans, and new measures in verse, as well as rhythms in music, which he had acquired from the flute-playing of Olympus, whom he at first had imitated. Porphyry, in his Life of Pythagoras, says that this philosopher used to amuse himself with singing the old Pæans of Thaletas; and Athenæus likewise tells us, that the Spartans long continued to sing his airs; and, according to the scholiast on Pindar, this poet-musician was the first who composed the Hyporchemes for the armed, or military dance.

There was another poet and musician of the name of Thaletas, who was likewise a Cretan, but who flourished much later than the cotemporary and friend of Lycurgus.

THALFANG, in *Geography*, a town of France, in the department of the Sarre; 11 miles S.S.W. of Traarbach.

THALHEIM, a citadel of Bavaria, in the territory of Nuremberg; 6 miles S.E. of Hersbruck.

THALIA, in *Botany*, was so named by Linnæus, in memory of John Thalius, a physician at Nordhausen, in Germany, who wrote *Sylva Hercynia*, a catalogue of the plants of the Hercynian forest towards Saxony, which accompanies the *Hortus Medicus* of Joachim Camerarius, both having been printed together at Francfort on the Maine in 1588; and they are both illustrated by excellent wooden cuts. Thalius died in 1587, of a fractured thigh, in consequence of a fall from his carriage. His work abounds with original descriptions and remarks; but as Haller observes, it is not easy to ascertain all the numerous species or varieties of which he treats. The genus before us was originally called *CORTUSA* by Plumier; but that name remains with a very different plant, as the reader will find in its proper place.—Linn. Gen. 4. Schreb. 6. Willd. Sp. Pl. v. 1. 15. Ait. Hort. Kew. v. 1. 3. Roscoe Tr. of Linn. Soc.

Soc. v. 8. 340. t. 20. f. 3. Brown Prodr. Nov. Holl. v. 1. 307. Pursh 584. Juss. 63. (Cortufa; Plum. Gen. 26. t. 8. Peronia; Redout. Liliac. v. 6. 342.)—Class and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juss. *Cannæ*, Brown.

Gen. Ch. *Cal.* Perianth superior, of three equal, ovato-lanceolate, permanent leaves. *Cor.* of one petal, irregular. Tube none. Limb double: the outer divided to the base into three equal, oblong, concave segments, much longer than the calyx: inner two-lipped; its upper lip convolute, abrupt, slightly three-lobed, hardly so long as the outer limb; lower twice as long, deeply three-lobed, with two awl-shaped appendages, the central lobe contracted in the middle. *Stam.* Filament one, declining, linear, depressed, the length of the upper lip, and attached to one of its edges; anther simple, ovate, of one cell, opening inwards. *Pist.* Germen inferior, roundish; style cylindrical, longer than the stamen, revolute; stigma irregular, ringent, perforated, beardless. *Peric.* Berry oval, of one cell, with a thin pulp. *Seed* solitary, large, oval, with a large horny albumen, and a solitary, central, curved embryo, accompanied by an empty cell.

Ess. Ch. Calyx of three leaves. Corolla of one petal, in five deep unequal segments, without a tube. Anther simple, ovate. Style recurved. Stigma ringent, perforated. Berry with one seed.

Obs. The characters and structure of the flower have in few genera been involved in so much uncertainty as in *Thalia*. We have endeavoured to draw up as correct a description as we could, from Mr. Sowerby's excellent plate of *Thalia dealbata*, published in 1794, by the late Mr. Frazer, and delineated under our inspection. Mr. Brown's learned remarks have assisted us as to the seed. The above description will be found to agree with Plumier's account of the original species, as far as any thing can be understood from thence; leaving little doubt that the two plants in question form one genus. Linnæus has left many manuscript corrections of his generic characters of *Thalia*, we know not from whence derived, which, though they accord as far as they go with our observations, do not supersede them. The present genus, no doubt, is next akin to *MARANTA*, but their differences will appear evident from a comparison of their descriptions. They both belong to the new order of *Cannæ*, or *Cannææ*, recently separated by Mr. Roscoe and Mr. Brown from the Linnæan *SCITAMINEÆ*. See that article.

1. *T. geniculata*. Distant-flowered *Thalia*. Linn. Sp. Pl. 3. Willd. n. 1. Swartz Obs. 9. (Cortufa arundinacea, amplis cannacori foliis; Plum. Gen. 26. Ic. 98. t. 108. f. 1.)—Leaves ovate. Flowers remote, alternate. Bractæas oblong.—Native of the West Indies, but hitherto seen by Plumier only. His figures are our only certain authority for this species; for Dr. Swartz has well observed, that the synonyms which authors have accumulated, do not belong to it; and that what Rottboll has described and figured, seems more akin to *T. cannaformis*, hereafter mentioned. We have indeed specimens, gathered by Mr. Frazer in 1810, in Cuba, near the Havannah, which greatly resemble Plumier's figure, and may be his plant, though from the impossibility of examining their fructification, we dare not assert them to be so. Nevertheless we shall describe them, that botanists may form their own opinion. The stem is several feet in height, erect, round, smooth, leafy, alternately branched. Leaves alternate, ovate, pointed, smooth, above a foot long, with one rib, and many fine transverse curved veins. Foot-stalk sheathing, compressed, half as long as the leaf, with an oblong, cylindrical knot at the summit. Panicle subdivided, with long, linear, obtuse, flat, erect scales, or general bractæas,

Vol. XXXV.

at each subdivision. Flower-stalks zigzag, knotty, round, two or three inches long. Partial bractæas two at each knot, the outermost much the largest, embracing and concealing the other, an inch in length, elliptic-oblong, green, finely ribbed, clothed with scattered shining hairs. Between these bractæas is situated a pair of flowers, whose dried corolla is partly purple, and whose pale, much convoluted and wrinkled lip bears some resemblance to Plumier's figure.

2. *T. dealbata*. Mealy *Thalia*. Roscoe. Tr. of Linn. Soc. v. 8. 340. Dryand. in Ait. n. 1. Pursh n. 1. Frazer's single plate. Curt. Mag. t. 1690. (Peronia stricta; Redout. Liliac. t. 342.)—Leaves ovate. Flowers crowded. Bractæas ovate, mealy.—Native of impenetrable swamps in South Carolina, flowering in August and September. Mr. Pursh says it was first discovered there by T. Millington, esq. Living plants were brought to England by the late Mr. Frazer in 1791, by which this handsome and curious species first became known to botanists. Its root is of course perennial. Stem four or five feet high, erect, round, smooth; leafy at the bottom; panicled at the top, covered with a silvery mealiness, which clothes also the general as well as partial bractæas, and is easily rubbed off by a touch. Leaves light green, smooth, above a foot long, on round sheathing stalks, with a knot at the top. General bractæas lanceolate, concave, convolute, a span long. Flower-stalks aggregate or compound. Partial bractæas crowded, in pairs, much more tumid, ovate, and shorter than in the foregoing, each pair containing two purple flowers, whose structure is detailed in our generic character. Fruit purple, the size of a hazel-nut, slightly pulpy.

3. *T. cannaformis*. Elliptical *Thalia*. Forst. Prodr. 1. Willd. n. 3. Buchanan in Symes's Embassy to Ava, ed. 2. v. 3. 305. t. 21.—Leaves elliptical. Partial bractæas linear-lanceolate, shorter than the divided partial flower-stalk.—Native of moist woods in the remote islands of the East Indies, and the New Hebrides, flowering in March and April. The stem is solid, branched, round, smooth, leafy, divaricated at the joints. Leaves alternate, broadly elliptical, pointed, smooth, on round sheathing stalks. Panicle terminal, with long, slender, pendulous branches, upon which the flowers are arranged pretty closely. Every pair of long narrow partial bractæas contains a divided stalk, bearing two large white flowers, each with the rudiment of another at its base. The corolla is somewhat tubular, and the lower lip of its inner limb has two large equal lobes, but in other respects the parts of fructification seem to answer well enough to the generic character. The fruit, however, which must settle that point, is unknown.

Our learned and highly valued friend Mr. Roscoe has suggested, that the *Marantia Cachibou*, Jacq. Fragm. Bot. 52. t. 69 and 70, of which we have a specimen gathered by Mr. Masson at St. Kitt's, may probably be a *Thalia*. Its seed certainly confirms this opinion, but the parts of the flower are not yet sufficiently described to authorize any conclusion, nor can we unravel their structure from the dried plant. Whatever becomes of this species, the *Marantia Casupo*, t. 63. f. 4, of the same work, and *M. Casupito*, t. 64. f. 2, must assuredly be referred to the same genus.

THALIA, in *Mythology*, one of the nine Muses, who presided over comedy and pastorals. She is distinguished from the other Muses by her mask, and from the tragic Muse by her shepherd's crook; her aspect is likewise meaner than that of Melpomene, and her dress shorter and less noble than that of the other Muses.

THALIA was also the name of one of the Graces.

THALICTRUM, in *Botany*, may possibly be, as generally

THALICTRUM.

rally supposed, the *θαλικτρον* of Dioscorides, from whom the name is adopted. That point, however, was not determined by Dr. Sibthorp, though he noticed five species of this genus in Greece or its neighbourhood. The above name is, by Ambrosini and others, derived from *θαλλω*, to be green and flourishing. Some old authors occasionally write it *Thalietrum*.—Linn. Gen. 280. Schreb. 277. Willd. Sp. Pl. v. 2. 1295. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 583. Prodr. Fl. Græc. Sibth. v. 1. 378. Ait. Hort. Kew. v. 3. 346. Pursh 388. Juss. 232. Tourn. t. 143. Lamarck Illustr. t. 497. Gärtn. t. 74.—Class and order, *Polyandria Polygynia*. Nat. Ord. *Mulifloriquæ*, Linn. *Ranunculaceæ*, Juss.

Gen. Ch. *Cal.* none, except the corolla be taken for such. *Cor.* Petals four or five, roundish, obtuse, concave, deciduous. *Stam.* Filaments numerous, dilated upwards, compressed, longer than the corolla; anthers terminal, oblong, erect. *Pist.* Germens superior, numerous, mostly stalked, roundish; styles none; stigmas thickish. There are also several very short imperfect pistils. *Peric.* none. *Seeds* several, ovate, furrowed, without any appendage.

Ess. Ch. Calyx none. Petals four or five. Seeds naked, without appendages.

Obs. Linnæus remarks, that his *T. tuberosum* and *cornutum* have five petals; *dioicum* has the stamens and pistils on separate plants; *aquilegifolium* and *contortum* have stalked pendulous seeds, furnished with three dilated or winged angles; moreover, that the number of stamens and pistils differs in the different species, being sometimes less than the characters of the class and order require.

This is a very distinct well-marked genus of perennial herbaceous plants, all natives of the cold or temperate climates of Europe and North America. The leaves are compound, with roundish, rarely oblong, lobed or notched leaflets; paler, or glaucous, underneath; usually smooth. *Inflorescence* panicled. *Flowers* white or yellowish, with some slight tinge of purple, generally of an elegant feathery appearance. Fourteen species are described in Linn. Sp. Pl.; twenty-one in Syst. Veg. ed. 14. Willdenow has twenty-three. Four are British. Nineteen are enumerated in Mr. Aiton's *Hortus Kewensis*. Their qualities in general are believed to be of an acrid nature, like those of *Ranunculus* and *Clematis*; but milder.

We have some additions and corrections to make, which require a compendious review of the whole genus.

1. *T. alpinum*. Alpine Meadow-Rue. Linn. Sp. Pl. 767. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 262. Lightf. 286. t. 13. f. 1. Fl. Dan. t. 11. (*T. minimum montanum atro-rubens, foliis splendentibus*; Raii Syn. 204. Boerh. Ind. Alt. v. 1. 44. t. 1.)—Stem perfectly simple, and almost naked. Cluster simple, terminal.—Native of moist black bogs, or the turfy margins of alpine rills, on the loftiest mountains of Lapland, Scotland, and Wales, flowering in June. The root is perennial, creeping, with a few simple fibres. Stem erect, about six inches high, round, glaucous or purplish, with one leaf, more or less compound, about the middle. Radical leaves several, stalked, erect, half as tall as the stem; first ternate; then either again ternate, or pinnate; the leaflets roundish, or wedge-shaped, veiny; glaucous beneath. Cluster at first drooping, then erect, of eight or ten alternate flowers, whose petals, and eight or ten filaments, are either white or purple; their anthers orange. Germens two or four only, roundish, green, each with a whitish, broadly-lanceolate, divaricated, downy stigma, about its own length. Linnæus describes twelve stamens, and eight pistils.

2. *T. fatidum*. Fetid Meadow-rue. Linn. Sp. Pl.

768. Willd. n. 2. Ait. n. 2. "Waldit. et Kitaib. Hung. v. 2. 190. t. 174." (*T. minimum fetidissimum*; Bauh. Prodr. 147. Pluk. Phyt. t. 65. f. 4. Morif. sect. 9. t. 20. f. 13. T. n. 1140; Hall. Hist. v. 2. 58.)—Stem panicled, round, leafy. Leaves triply compound, minutely downy on both sides. Flowers drooping. Petals slightly hairy. Stigmas auricled at the base.—Native of France, Switzerland, and Siberia, flowering in May. A species of a delicate aspect, and glaucous hue, about a foot high, with innumerable, small, rounded, lobed, tender leaflets. The petals are externally reddish, especially in the young plant, and finely downy or hairy. Stamens long and capillary. Seeds ovate, strongly furrowed, crowned with the permanent shrivelled stigmas, whose dilated or auricled base is distinguishable in our Swiss specimens. This last character is, in the *Supplementum*, p. 271, made the peculiar mark of *T. styloideum*, there described from a Siberian specimen, which Linnæus did not recognize as his own *T. fatidum*. The *styloideum*, Willd. n. 22, is therefore to be struck out. Several Swiss botanists have confounded the species before us with *T. minus*, hereafter described, which is Haller's n. 1139. That eminent writer had some doubts respecting the difference between the two, which we shall attempt to remove when we come to the other, Linnæus having placed them far asunder. The *fatidum* is said to exhale a very bad and powerful odour, like *Geranium robertianum*, or, as Haller says, the urine of cats.

3. *T. tuberosum*. Tuberos-rooted Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 3. Ait. n. 3. Mill. Ic. v. 2. 177. t. 265. f. 2. (*Oenanthe Myconi*; Dalech. Hist. 785. *Ranunculus thalictri folio minor, aphodeli radice*; Morif. sect. 4. t. 28. f. 13.)—Leaflets rounded, glaucous, smooth. Petals five. Root tuberous.—Native of Spain and the Pyrenees. A hardy perennial in our gardens, flowering in June, but confined to the more curious collections. The root consists of ovate knobs. Herb smooth, a foot or more in height, of a light glaucous green. Flowers panicled, not numerous, distinguished by their five large, ovate, white petals, and small stigmas. Morison's figure is badly copied from that of Dalechamp.

4. *T. Cornuti*. Canadian Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 4. Ait. n. 4. Pursh n. 1. (*T. canadense*; Cornut. Canad. 186. t. 187. *T. femine triquetro, foliis aquilegiæ*; Morif. sect. 9. t. 20. f. 15.)—Leaflets rounded, three-lobed, glaucous, smooth. Panicles terminal. Flowers dioecious. Petals five. Root fibrous.—On the banks of rivers, and in wet meadows, from Canada to New England, flowering in June and July. Root perennial. Stem from two to three feet high. Flowers small, greenish-yellow. Pursh. Cornuti says the unexpanded petals are pale purple; the stamens white, numerous, with yellow anthers. Seeds triangular. The dioecious nature of the flowers, which we have had no opportunity of observing, was first noticed in Hort. Kew.

5. *T. dioicum*. Dioecious Early Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 5. Ait. n. 5. Pursh n. 2. Muhlenb. Cat. 54.—Leaflets heart-shaped, many-lobed, very smooth. Panicles axillary. Flowers dioecious. Petals not longer than the filaments or germens. Stigmas almost capillary.—Native of shady woods and the banks of rivers, from Canada to Virginia, flowering from May to July, according to Pursh, who says the flowers are white. He conceives his plant to be the same with *T. levigatum* of Michaux, Fl. Boreali-Amer. v. 1. 322, who confesses his inability to determine the North American *Thalictro*, they being almost all dioecious. Specimens from the late Dr. Muhlenberg, new before us, and agreeing exactly with those sent by Kalm to Linnæus,

THALICTRUM.

Linnæus, as recorded in Sp. Pl., are certainly dioecious, about a foot high, very smooth, with thrice-ternate leaves, whose lobes are usually from five to seven, blunt, and rather shallow; both their surfaces reticulated with slightly prominent veins. Panicles solitary or in pairs from the bosoms of the leaves, somewhat umbellate, on long stalks, and often accompanied by a long-stalked solitary flower. Petals of the male flowers white or reddish, ovate, ribbed, the length of the very slender numerous filaments, whose anthers are yellow, very narrow, pointed; those of the female flowers much smaller and rounder, white or greenish, hardly so long as the little, oval, ribbed germens. The stigmas are very slender, and remain in a prominent, almost capillary, form, on the ovate-oblong, striated seeds.

6. *T. elatum*. Tall Meadow-rue. Jacq. Hort. Vind. v. 3. 49. t. 95. Willd. n. 6. Ait. n. 6.—Leaflets ovate, three-lobed, smooth, somewhat notched. Panicle much branched, terminal. Flowers erect. Filaments capillary. Stigmas ovate, short.—Native of Hungary. Introduced into England by Mr. Hunnemann in 1794. A hardy perennial, flowering from June to August. Aiton. An unnamed specimen in the Linnæan herbarium manifestly agrees with Jacquin's plant, which is four feet or more in height. The stem is more furrowed in our specimen than he represents. The leaves are ternate from their very base, then twice or thrice pinnate, glaucous, incorrectly three-lobed, and somewhat cut besides. Flowers white, erect, in an upright compound panicle. Petals ovate, rather small, sometimes purplish. Filaments of equal thickness throughout, about thrice the length of their oblong, linear, pointed anthers, which Jacquin represents rather shorter and rounder than we find them. Germens angular. Seeds elliptic-oblong, glaucous, furrowed, crowned with the short shrivelled stigmas.

7. *T. majus*. Greater Meadow-rue. Jacq. Austr. v. 5. 9. t. 420. Willd. n. 7. Fl. Brit. n. 3. Engl. Bot. t. 611.—Leaflets roundish, somewhat heart-shaped, three-cleft; glaucous beneath. Panicle leafy, with aggregate branches. Flowers drooping.—Native of woods and bushy places in Austria, Hungary, Mount Athos, and the north of England, perennial, flowering in June and July. The late Mr. Robson of Darlington found it at Baydales, near that town, as well as on the margin of Ulls-water, Cumberland. This is about the size of the last, but the leaves are of a darker green on the upper side, very glaucous beneath. The branches of the panicle grow several together, from the bosoms of the upper leaves, and the flowers, at least their stamens, are pendulous, with longer anthers than the preceding. The petals moreover are green. In the germens and stigmas we perceive no particular distinction.

8. *T. medium*. Intermediate Meadow-rue. Jacq. Hort. Vind. v. 3. 50. t. 96. Willd. n. 8. Ait. n. 8.—Leaflets oblong-wedge-shaped, three-cleft, notched; the uppermost lanceolate. Panicle much branched, slightly leafy. Stamens spreading.—Native of hilly situations in Hungary. A hardy perennial, flowering in June and July, introduced at Kew, by Mr. Hunneman, in 1789. Specimens in the herbarium of Linnæus, from the Upsal garden, which he suspected might be *T. tuberosum*, n. 3, appear rather to belong to the present species, which differs from the two last in the narrowness of its leaflets, agreeing with them in the germens and stigmas. The panicle is more like *elatum* than *majus*. The stamens are not pendulous, but divaricated. Petals elliptical, greenish. Leaves light green, somewhat glaucous.

9. *T. minus*. Lesser Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 9. Fl. Brit. n. 2. Engl. Bot. t. 11. Fl. Dan.

t. 732. Jacq. Austr. v. 5. 9. t. 419. Segu. Veron. 476. Vill. Dauph. v. 3. 713. Ger. Em. 1251. (*T. alpinum minus saxatile, rutæ folio, staminibus luteis*; Segu. Veron. 476. t. 11.)—Leaflets roundish, three-cleft, notched, somewhat glaucous on both sides. Panicle slightly leafy. Flowers pendulous.—Native of various parts of Europe, from Sweden to Greece, generally on a limestone or chalky soil, flowering in June and July. Our British plant precisely agrees with what was found in Gothland by Linnæus, though he subsequently confounded "things innumerable, both small and great," under *T. minus*. The true one is a bushy spreading herbaceous perennial, of humble growth, generally but a foot high, smooth, of a glaucous hue, with tints of violet. Leaflets rather small, various in breadth. Panicle moderately branched. Flowers pendulous, though the stalks become more erect when in seed. Petals elliptical, concave, light purple, sometimes jagged or fringed. Stamens capillary. Anthers long, linear, pointed, as in the last. Germens and seeds small. Linnæus's specific definition, *foliis sexpartitis*, has puzzled every body, and is inapplicable to any thing ever taken for the present species. He perhaps meant that each leaf consisted of six primary divisions, which is mostly the case.

10. *T. rugosum*. Rugged Meadow-rue. Ait. ed. 1. v. 2. 262. ed. 2. n. 10. Willd. n. 10. Pursh n. 3. Muhlenb. Cat. 54.—Leaflets ovate or lanceolate, rugged, veiny, bluntly lobed. Stem round, striated. Panicle corymbose. Flowers erect.—On the banks of rivers, and in swamps, from Pennsylvania to Carolina, flowering from June to August. Perennial, very tall, sometimes above five feet high. Flowers white. Pursh. The habit of this plant is more like some of the large species hereafter described, with a large terminal dense, almost leafless, tufted panicle. Stamens capillary. Anthers linear.

11. *T. sibiricum*. Siberian Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 11. Ait. n. 11. (*T. orientale minimum, fumariz folio*; Tourn. Cor. 20. Willd.)—"Leaves in three divisions; leaflets somewhat reflexed, sharply cut. Flowers drooping."—Found by Gmelin in Siberia; and by Tournefort, if we are right in his synonym, in Armenia. Linnæus doubtingly cites a synonym of Seguir, which, after Haller, we have referred to *T. minus*. His account of the present species, of which we know nothing, is, that its habit accords with *T. minus*, or *purpurascens*, but the leaflets are small, but one-sixth as large as those species, glaucous like Rue or Fumitory. Stem green, copiously panicled. Panicle brown at its divarications. It flowers later, at the same time as *flavum* and *dioicum*.

12. *T. squarrosum*. Squarrose Meadow-rue. Willd. n. 12.—"Leaflets three-cleft or undivided. Footstalks membranous, winged, clasping the stem. Flowers drooping."—Native of Siberia. Differs from all the foregoing species which have drooping flowers, in the structure of its footstalk. The leaves are repeatedly compound, as in the rest; their lateral leaflets mostly ovate, acute, and entire, but the terminal, and even the uppermost lateral ones, are divided or three-cleft. Footstalk greatly dilated at the base, with orbicular membranous wings, toothed at the margin. There are also lesser orbicular toothed auricles, upon the partial footstalks, by which mark the species is easily known. Willdenow. We have met with nothing answering to this description.

13. *T. purpurascens*. Purplish Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 13. Ait. n. 12. Pursh n. 5.—(*T. virginianum elatius glaucum, florum staminibus purpurascens*; Morif. v. 3. 324.)—"Stem twice as tall as the leaves. Leaflets roundish, three-cleft, cut. Panicles

nearly naked. Flowers drooping. Stamens coloured."— On dry sunny hills, in Pennsylvania and Virginia. Perennial, flowering in May and June. A small plant. *Stem* and *filaments* purple. *Pursh*. Linnæus contrasts this with *T. minus*, a species concerning which his ideas were too vague, for us to learn any thing from such a comparison, nor does his herbarium lend us any certain aid. There is, however, an unmarked specimen, which he associated with *T. dioicum*, but which may possibly be the *purpurascens*. It has broad ivy-like leaflets, but is more particularly distinguished by short elliptical *anthers*, whose *filaments* are gradually dilated upwards, approaching to those of *T. flamineum* hereafter described.

14. *T. pubescens*. Downy Polygamous Meadow-rue. *Pursh*. n. 4. *Muhlenb. Cat.* 54.—Leaflets ovate, somewhat heart-shaped, or wedge-shaped; three-lobed at the end; slightly downy beneath. Panicles terminal. Flowers polygamous. Anthers linear. Styles awl-shaped, twice as long as the germens.—On the banks of ditches and rivulets, in Pennsylvania and Virginia, flowering from June to August. A tall species, with white flowers. *Pursh*. We have this from our late venerable correspondent, the Rev. Dr. Muhlenberg. The leaflets are rather large; dark green, and somewhat rugged, above; paler, reticulated with prominent veins, and minutely downy, at the back. Flowers nearest to those of *T. dioicum*, and like them distinguished by long tapering stigmas. The anthers are linear-oblong; their filaments almost equally slender throughout.

15. *T. angustifolium*. Narrow-leaved Meadow-rue. *Linn. Sp. Pl.* 769. *Willd. n.* 14. *Ait. n.* 13. *Jacq. Hort. Vind. v. 3. 25. t. 43.*—Leaflets linear-lanceolate, or linear, mostly undivided, entire. Panicle much branched, dense. Flowers erect. Stigmas heart-shaped, half the length of the germens. Native of Switzerland and Germany, but not frequent any where. Dr. Sibthorp, however, gathered it on the Bithynian Olympus. Miller seems to have cultivated it, in his time, at Chelsea, but we have scarcely ever seen a living specimen, and we are much inclined to concur in opinion with those who judge it a variety of the following, their habit, inflorescence, and flowers, being exactly the same, however different the breadth of their leaflets. Bauhin's synonym, uniformly referred to this, certainly belongs to *T. simplex*, n. 17.

16. *T. flavum*. Common Meadow-rue. *Linn. Sp. Pl.* 770. *Willd. n.* 15. *Fl. Brit. n.* 4. *Engl. Bot. t.* 367. *Fl. Dan. t.* 939. (*T. nigricans*; *Jacq. Austr. v. 5. 10. t. 421.* *Willd. n.* 16. *T. nigrius*, caule et femine striato; *Bauh. Hist. v. 3. 486.* *T. majus*, foliis rugosis trifidis; *Morif. sect. 9. t. 20. f. 3.*)—Leaflets rounded or oblong, three-cleft. Panicle much branched, dense. Flowers erect. Stigmas heart-shaped, half the length of the germens.—Found in moist meadows, and the reedy margins of rivers, throughout Europe, from Sweden to Greece, flowering in July. The root is yellow, perennial. Stem three feet high, erect, smooth, leafy, furrowed or angular, simple below. Leaves nearly sessile, twice ternate, with a short sheathing base, or footstalk; leaflets slightly glaucous, most so beneath; either undivided or three-cleft, entire, veiny, varying extremely in breadth, length, and sharpness. Panicle terminal, erect, dense, corymbose, much branched, somewhat leafy. Flowers and stamens erect, yellowish-white, with oblong, slightly pointed, yellow anthers. Stigmas oblique, heart-shaped, downy. Seeds deeply furrowed. The vague resemblance of this plant to the garden rue, and its place of growth, seem to have given the English name of the whole genus. Jacquin's *nigricans*, found frequently in England, differs merely in the elongation and comparative narrowness

of its leaflets, which approach in those respects to the *angustifolium*, last described.

17. *T. simplex*. Simple-stalked Meadow-rue. *Linn. Mant. 78*, excluding the synonym. *Willd. n.* 17. *Ait. n.* 15. *Fl. Dan. t.* 244. *Ehrh. Phytoph. 15.* (*T. angustifolium*; *Villars Dauph. v. 3. 712.* *T. angustissimo folio*; *Bauh. Prodr. 146.* *Morif. sect. 9. t. 20. f. 8.*)—Leaflets linear. Stem angular, simple. Panicle branched, compound, lax, somewhat racemose. Flowers pendulous. Stigmas roundish-heart-shaped.—Native of Sweden, Denmark, Switzerland, and France. Introduced at Kew by the very eminent cultivator and botanist M. Thouin, in 1778. It is a hardy perennial, flowering in May and June. This is unquestionably akin to the last, but essentially distinct. The whole plant is but half as large, with a much more angular stem. The leaflets are extremely narrow, and revolute, unaccompanied by any of the partial stipular scales, seen on the leaves of *T. flavum*. The panicle is more oblong and lax, not corymbose. Flowers smaller, drooping, or rather quite pendulous, not erect. Petals green, not white or yellowish. Stigmas remarkably round and convex. We have specimens from Villars, which prove the correctness of Willdenow respecting his synonym. We have also from professor Lachenal a specimen gathered at Michelfeld, which shews this to be the plant of Bauhin, cited by Linnæus and others for *T. angustifolium*. Indeed Bauhin's wooden cut, copied by Morison, sufficiently evinces this, though, being delineated perhaps from a dried specimen, it is not exact in the position of the flowers. *T. gallioides*, *Willd. Enum. Hort. Berol. 585.* we believe is a very narrow-leaved variety of *simplex*.

18. *T. lucidum*. Shining-leaved Meadow-rue. *Linn. Sp. Pl.* 770. *Willd. n.* 18. *Ait. n.* 16. (*T. minus lucidum*, *libanotis coronariae foliis*; *Pluk. Phyt. t. 65. f. 5.*)—"Stem leafy, furrowed. Leaflets linear, fleshy."—Said to be a native of France and Spain. Miller had something in his garden which passed for this plant, and hence it is enumerated in *Hort. Kew*. We have never seen a specimen, nor did Linnæus know any more of the matter than what Dalibard, whose specific character we more exactly copy, has given in his *Fl. Paris. 162*. The late Mr. Davall sent us a Swiss *Thalictrum* for *lucidum*, which answers to the character, but is indubitably the *simplex* in a luxuriant state. Linnæus thought the *lucidum* was probably a variety of *flavum*. We presume various things have been taken for this plant, but in reality that it has no existence as a species.

19. *T. aquilegifolium*. Columbine-leaved Meadow-rue, or Feathery Columbine. *Linn. Sp. Pl.* 770. *Willd. n.* 19. *Ait. n.* 17. *Jacq. Austr. v. 4. 10. t. 318.* *Curt. Mag. t. 1818.* (*T. atropurpureum*; *Jacq. Hort. Vind. v. 3. 34. t. 61.* *T. majus*, *florum staminibus purpurascens*; *Bauh. Pin. 337.* *Morif. sect. 9. t. 20. f. 16.*)—Leaflets rounded, lobed, and cut. Stem round. Panicle corymbose. Flowers erect. Stamens dilated upwards. Germens stalked. Fruit pendulous, with three dilated wings.—Native of Sweden, Germany, Switzerland, Thrace, and Greece, common and hardy in our gardens, flowering from May to July. The stem is three or four feet high, round, somewhat striated, leafy, smooth, either glaucous or purple. Leaves large and spreading, much resembling those of *Aquilegia vulgaris*, though often more acute. Flowers large and elegant, white or pale violet; their petals reflexed; their very numerous stamens moderately dilated upwards, flattened, of the hue of the petals, with short yellow anthers. Germens triangular, on long stalks, at length deflexed or pendulous, and becoming somewhat obovate, obtuse, straightish seeds, with three unequal, much dilated, smooth wings.

wings. Retzius, in his *Obs. Bot. fasc. 6. 30. sect. 52*, justly indicates the identity of Jacquin's *T. atropurpureum* and the Linnæan *aquilegifolium*, confessing he could not decide concerning the *aquilegifolium* of Jacquin. We have a wild Swiss specimen of the latter, Haller's n. 1141, precisely answering to the plate in *Fl. Austria*, and certainly not differing in any essential character from the true plant of Linnæus, so frequently cultivated for ornament, and preserved in his herbarium.

20. *T. contortum*. Twisted-seeded Meadow-rue. Linn. Sp. Pl. 770. Am. Acad. v. 4. 47. Willd. n. 20. Ait. n. 18.—“Fruit pendulous, triangular, contorted. Stem rather two-edged.”—Native of Siberia. Linnæus thought it a hybrid offspring of *aquilegifolium* impregnated by the *minus*. His specimen is not to be distinguished from the former, and we cannot but agree with Willdenow's remark, that the contortion of the *seeds* is merely a sign of imperfection. Neither can any more solid dependance be had on the comparative number of the parts of fructification, on the white colour of the *flowers*, or the humbler stature of the herbage. We conclude this supposed species therefore to be scarcely even a variety of the last.

21. *T. petaloideum*. Daurian Meadow-rue. Linn. Sp. Pl. 771. Willd. n. 21. Ait. n. 19. (*T. flamineum*; Linn. Suppl. 271.)—Leaflets rounded, obtuse; partly three-lobed. Stem nearly leafless. Panicle somewhat umbellate. Stamens much dilated, linear-obovate. Germens sessile.—Native of Siberia. Mr. Loddiges is said to have introduced this curious and very distinct species to the knowledge of our cultivators, in 1799. It has a perennial root, with long, simple, rather fleshy fibres. Stem simple, about a foot high, striated, purple at the bottom, leafless, except an occasional leaf, accompanying a small lateral branch. Radical leaves two, spreading, thrice compound, on purplish stalks; leaflets very much like Common Rue, but smaller. Flowers white, large but not numerous, in a sort of corymb, or imperfect umbel, accompanied by a few small leaflets. Petals roundish, deciduous. Stamens very numerous, white, flat, and singularly dilated, with a mid-rib; their anthers yellow, narrow and short. Germens ovate, ribbed, with awl-shaped recurved stigmas. Willdenow makes *T. flamineum* a variety, little supposing that the very identical specimens, so minutely and accurately described in the *Species Plantarum*, could be again described, without a reference, in the *Supplementum*.

We have to exclude *T. japonicum*, Thunb. Tr. of Linn. Soc. v. 2. 337. Willd. n. 22, a specimen from Thunberg himself proving it to be no other than *Coptis asplenifolia* of Mr. Salisbury, Tr. of Linn. Soc. v. 8. 306, a circumstance as wonderful as that its discoverer should ever have thought this plant similar to a *Salvia*. See *Fl. Jap.* 364.

T. ranunculinum, Willd. Enum. Hort. Berol. 585. Pursh n. 6, having simple leaves, and being not noticed as a *Thalictrium* by Muhlenberg himself, who is quoted for it, is, we presume, best omitted here; as well as *T. concinnum*, Willd. Enum. 584, which is probably comprehended under some of the foregoing species.

THALICTRUM, in Gardening, contains plants of the hardy, herbaceous, fibrous-rooted, perennial kinds, among the number of which the species mostly cultivated are; the tuberous-rooted meadow-rue (*T. tuberosum*); the Canadian meadow-rue (*T. cornuti*); the fetid meadow-rue (*T. fetidum*); the narrow-leaved meadow-rue (*T. angustifolium*); the shining-leaved meadow-rue (*T. lucidum*); and the columbine-leaved meadow-rue, or feathered columbine (*T. aquilegifolium*).

In the second sort there is a variety, which is smaller, with pale purple filaments, than the common kind.

Also in the sixth sort there are varieties with a green stalk and white stamens, and with a purple stalk and stamens. Besides, there are other sorts that may be cultivated for variety.

Method of Culture.—All the sorts are readily increased by parting the roots, and planting them out in the autumn when the stems decay, or in the spring before the new ones are set forth, the strongest where they are to remain, and the weaker ones in nursery-rows for further growth: they may also be raised from seeds, which should be sown in a bed or border in the spring: when the plants rise, they should be kept clean, and be planted out where they are to remain, in the following autumn. They are all hardy durable plants that succeed and grow well in any common soil and exposure in the open ground, but which flourish most in moist shady situations. They afford variety in the borders, and other parts of ornamented grounds, when set out in a properly varied manner, requiring but little trouble or attention in such situations.

THALINA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, upon the banks of the Euphrates. Ptol.

THALLABA, TALABAN, a town of Asia, in Mesopotamia, upon the banks of the river Chaboras, situated E.S.E. of Resæina.

THALLAND, in *Geography*. See DALIA.

THALLITE, in *Mineralogy*; *Epidote*, Haüy; *Delphinite*, Saussure; *Shorl vert du Dauphiny*, Romé de Lisle; *Acaticene*, Dendrada; *Pistacit*, Werner. Few minerals have received so many names as this: it is at present better known by the name of epidote or thallite. It has frequently been confounded with actinolite or strahlstein, and with green hornblende and green asbestos. Some account of this mineral is given under PISTACITE. We shall here add its distinctive characters and constituent parts. From actinolite it may be distinguished by the colour, the latter being generally a lighter green. The structure of the massive varieties of actinolite is generally radiated, that of epidote compact or foliated. Both the joints of actinolite are distinctly seen; but in epidote, frequently one joint only is seen. Epidote melts into a blackish scoria before the blowpipe, and is harder than actinolite or hornblende; the latter has generally a different shade of green: the fracture of hornblende is also less vitreous than that of epidote. Green asbestos is soft when pounded; the powder of epidote is harsh and rough. Thallite or epidote occurs both massive and crystallized. The joints are in two directions, one of which is more obvious than the other. The alternate angles are about $114\frac{1}{2}^{\circ}$ and $65\frac{1}{2}^{\circ}$; the cross fracture is splintery. The primitive form of the crystal is a prism with rhomboidal bases. The most common forms are six or eight-sided prisms, of which four are larger than the others. These prisms are terminated by several oblique planes, and are often flatly acuminate: the terminating planes of the crystals are smooth, and have a high natural polish; they are sometimes convex. The lateral planes, or sides of the crystals, are striated. This mineral is found in beds and veins, and sometimes as a constituent part of rocks. It is associated with augite, garnet, hornblende, quartz, calcareous spar, and magnetic iron-stone. The varieties that occur in veins are of a lighter colour, and the crystals are more acicular than those which are found in beds. The veins contain feldspar, axinite, rock-crystal, chlorite, and other minerals; the epidote forming only a small part of the substance of the vein. It is found in several parts of the Scotch Hebrides, and in various alpine districts, in sienite, porphyry, and granitic rocks. The finest crystals have been procured at Arundel in Norway. The constituent

fituent parts of this mineral, from different situations, agree more nearly than is frequently the case with other minerals.

	From the Valais.	From Oisans.	From Arundel.

It differs in chemical composition from hornblende and actinolite, by the absence of magnesia, and by the large proportion of alumine which it contains.

THALLOPHORI, *Θαλλοφοροι*, in *Antiquity*, the old men and women, who, in the procession of the festival *panathenæa*, carried olive-boughs in their hands.

THALLUS, in *Botany and Vegetable Physiology*, *Θαλλος*, an olive bud, or a green bough; from *θαλλω*, to be verdant, to shoot forth, or spread abroad; a term aptly enough chosen by the distinguished professor Acharius, for the froed, or foliage, of a *Lichen*, whether that part be of a leafy, fibrous, scaly, or crustaceous nature. But this term, however apt, is superfluous, *frons*, used by Linnæus, being synonymous with it, and sufficient for every requisite purpose. See **LICHEN** and **LICHENES**; also **FROND**.

THALMANSFELD, in *Geography*, a town of Germany, in the margravate of Anspach; 4 miles W. of Thalmessing.

THALMESSING, or **THALMESSINGEN**, a town of Germany, in the principality of Anspach; 31 miles S.E. of Anspach. N. lat. 49° 1'. E. long. 11° 10'.

THALMIS, or **TALMIS**, in *Ancient Geography*, a town of Egypt, between Taphis and Tutzis. Anton. Itin.

THALPUSA, a town of the Peloponnesus, in Arcadia; which belonged to the Orchomenians.

THALSEA, or **THELSEA**, a town of Phœnicia, marked on the route from Remmaris to Neapolis, between Geroda and Damascus.

THALUDA, a river of Africa, in Mauritania Tingitana, the mouth of which is placed by Ptolemy on the coast of the Iberian sea, between Jagath and the promontory Oleastrum.

THALYSIA; *Θαλυσια*, in *Antiquity*, a sacrifice offered by the husbandmen after harvest. For the origin and ceremonies of which, see Potter, *Archæol. Græc.* tom. i. p. 400.

THAMALAPATHRA. See **FOLIUM Indicum**.

THAMAR, a word used by the Arabian physicians to express a date. Hence a pectoral decoction, made with dates and other ingredients, was called *diathamyron*; and the word was afterwards corruptly written *dicameron*.

THAMAR, in *Ancient Geography*, a town of Judea, near Malis or Malath, which, according to Eusebius, had a Roman garrison.

THAMARITA, a town of Africa, in Mauritania Cæsariensis.

THAMARO, a town of Palestine, on the western side of Jordan. Ptolemy.

THAMASCHALTIS, a town of Africa Propria, on the route from the Greater Leptis to Tacapæ, between Thramusdis and Thentei. Anton. Itin.

THAMBES, in *Geography*, a mountain of Algiers; 30 miles S. of Bona.

THAME. See **TEAM**.

THAME, or *Tame*, in *Geography*, a market-town in a hundred of the same name, and county of Oxford, England, is situated on the banks of the river Thames (whence it derives its name), at the north-eastern extremity of the county adjoining to Buckinghamshire, 13 miles E. from Oxford, and 46 miles

N.W. by W. from London. Dr. Stukeley calls this place *Tamefe*, and it is unquestionable that a Roman military road went through the town, though it was by degrees neglected in the latter times of the empire. Thame was a place of some consequence in the tenth century; for we find that Wulfere, king of Mercia, granted a charter "in the vill called Thama;" and in the year 970, Osketyl, archbishop of York, is known to have died here. In 1010, when the Danes over-run these parts of the kingdom, this town, among others, suffered severely. The Domesday record describes the manor of Thame as a part of the bishop of Lincoln's extensive possessions in Oxfordshire. Leland says, "about Alexander, bishop of Lincoln's time, the town of Tame, being the king's, was given for rent, in fee-farm to the bishop of Lincoln and his successors." To the patronage of the bishops the town was indebted for numerous advantages. By them the church was erected, the vicarage and a prebend endowed, and a neighbouring abbey reared: Through their interest the fairs and market were granted; and Henry Lexington, bishop in Henry the Third's reign, rendered an important service, by turning the high road through the middle of the town. Thame continued dependant on the bishops till the reign of Edward VI., when the fee was dismembered of many of its valuable possessions. Sir John Williams obtained a grant of the estate, which descending by marriages to the family of Bertie, it became vested in the earls of Abingdon, the present possessors. During the civil wars of the seventeenth century, Thame was surrounded by garrisons of the contending parties, and consequently experienced its full share of the miseries of that period. The town consists principally of one long and spacious street, gently rising from the river. The church is a large, well-built structure, of the cruciform description, and comprises a nave, two aisles, a north and south transept, and a chancel; with an embattled tower supported by four massy pillars. The interior exhibits numerous tombs and memorials of families once important in this neighbourhood. Near the church are the remains of the prebendal house, which evince considerable former grandeur, and consist of nearly three sides of a quadrangle. A school, once of great celebrity, was founded here by John, lord Williams: the house is a spacious building, and the school of noble dimensions. Through the whole of the seventeenth century, this establishment maintained a high character: but has now fallen into disuse; though the building is in excellent preservation. There is likewise a charity-school of an humble description for the education of twenty-five boys. Thame has a good weekly market on Tuesdays, and two annual fairs: the market is of ancient date, for we find that the prior of Rufford was restrained from holding a market at Haddenham, to the prejudice of that of Thame. In the year 1811, the number of houses was returned as 460; the population as 2328, of which more than half were paupers receiving alms from the parish. By the return of the expences attending the maintenance of the poor in 1811, those of this parish amounted to 3686*l.*, a sum exceeding the expenditure of any other parish in the county. The parish contains about 4600 acres of land, and is divided into six hamlets or liberties, Old Thame, New Thame, Priest End, Thame Park, Moreton, and North Weston: the town comprises the three first. In Thame park, about a mile from the town, stood an abbey of some importance, established by bishop Alexander in 1138. At the dissolution, the society consisted of an abbot and sixteen monks; and the annual revenue was 256*l.* 1*4s.* 7*d.* The abbey, with all its possessions, was surrendered to the crown by Robert Kyng, the last abbot, who, for his ready compliance, was on the erection of the see of Oxford appointed its first bishop. On the site of

a part of the abbey the present mansion was built by Philip, the father of the late lord Wenman. Considerable fragments of the abbey still remain, which are protected by the modern elevation. The park contains about 220 acres, and is skirted with woodland.

Sir John Holt, the celebrated chief justice of the court of king's bench, was born at Thame in 1642, and died in 1709. (See *HOLT, Sir JOHN.*)—*Beauties of England and Wales*, vol. xii. Oxfordshire; by J. N. Brewer.

THAMES, the name of the most important river of Great Britain, is pre-eminently distinguished for its commercial consequence, the scenery, edifices, and towns on its banks; for the bridges which are raised across its channel; for the vast docks, quays, and warehouses which are annexed to it; and for the variety and interest of the historic occurrences which are connected or associated with its name. Yet, though so eminent at the present time, it was neglected in former ages; and it is singular to remark, that its source and early progress have occasioned much doubt and dispute. Some topographers have assigned its origin to a spot in Oxfordshire, near the town of Thame; while others, with more regard to probability and record, have traced its source to a spring near Cricklade, in Wiltshire. In that district three or four streams emerge from the earth, and each of these has been honoured with the appellation of Thames-head: but at present it is very generally admitted, that this name strictly belongs to a fine spring, which rises in the parish of Kemble, in Wiltshire, about five miles N.W. of Cricklade, and two and a half miles S.W. of the town of Cirencester. Some writers state that the spring-head is in the parish of Cotes, and county of Gloucester. As a proof that this stream was designated as the Thames, or Tems, at an early period, we may refer to a Saxon charter of Malmesbury Abbey, wherein it is named "Temis," as the boundary of certain lands. Again, some of the old Monkish historians state that the Danes crossed the Thames at Cricklade in the early part of the tenth century.

It has been erroneously said, that the name of this river is the *Isis* till it arrives at Dorchester, and receives the waters of the Thame, where it attained the compound name of *Thamesis*. Some old Oxford poets have given currency and celebrity to this story. Pope, in his "Windfor Forest," speaking of the union of various streams with this river, thus sings:

"First the famed authors of its ancient name,
The winding Isis, and the fruitful Thame;
The Kennet swift, for silver eels renowned;
The Loddon slow, for verdant alders crowned;
Cole, whose dark streams his flowery islands lave,
And chalky Wey, that rolls a milky wave."

Denham, the poetical encomiast of "Cooper's Hill," thus characterises the Thames.

"My eye descending from the hill, surveys
Where Thames among the wanton vallies strays.
Thames the most loved of all the Ocean's sons
By his old sire to his embraces runs;
Hasting to pay his tribute to the sea,
Like mortal life to meet eternity."

The nature of the present work will not allow of a particular description of the course of this river, with brief accounts of all the prominent objects on its banks. It must suffice to specify the names of the towns, chief seats, and prominent features; and refer to the former, under their respective names in the Cyclopaedia, for further information, and to such books wherein the best accounts are to be obtained. One characteristic of this river is entitled to notice; and which

shews, that at the original formation of shires, and subdivision of lands in England, the Thames was at that time a noted and considerable stream. From the town of Cricklade, to its junction with the sea at Sheerness, this river is a boundary, or natural line of separation, to counties. Soon after its source, it divides the counties of Wilts and Gloucester; next, those of Oxford and Berks, and Buckingham and Berks; afterwards Middlesex and Surrey; and, lastly, Kent and Essex. The Thames is also a navigable river nearly the whole of its course, and thus affords an easy and cheap passage for heavy goods from the ocean, and the port of London, to the interior parts of the island. By means of a canal, extending from the town of Lechlade, in a north-westerly direction, to the river Severn, the latter great western river and the Bristol Channel are joined by a navigable course to the English Channel. See *CANAL, THAME, and SEVERN.*

As nearly the whole course of the Thames is through a plain or level country, we find its current is consequently flow and irraguous: for fifteen or twenty miles it is only a narrow and small stream, but after receiving the waters of several rivulets, it assumes a river-like appearance at Lechlade, and is capable of sustaining barges of 100 tons burthen. From that town (about 138 miles by water from London) to Sheerness, it is strictly a navigable river. In its course to the sea, the following rivers, besides several smaller streams, pour their waters into the Thames: the Wainrush, Evenlode, Cherwell at Oxford, Thame, Kennet, Loddon, Coln, Wey, Mole, Brent, Lea, Roding, Dart, and Medway.

The following cities, towns, and large villages are seated on the banks of this river: *viz.* the cities of Oxford, London, and Westminster; the towns of Cricklade, Lechlade, Abingdon, Wallingford, Henley, Great Marlow, Maidenhead, Windsor, Staines, Kingston, Richmond, Brentford, Greenwich, Woolwich, and Gravesend; the villages of Pangbourn, Wargrave, Eton, Datchet, Old Windsor, Shepperton, Walton, Sunbury, Moulsey, Hampton and Hampton-Court, Twickenham, Isleworth, Barnes, Chiswick, Fulham, Putney, Hammer-smith, Chelsea, Blackwall, &c. The banks of this river are also ornamented with the palaces of Windsor, Hampton-Court, Kew, Fulham, and Lambeth: likewise the following distinguished seats of English nobility and gentry, besides several smaller villas, &c.; Nuneham-Courtney, Basildon House, Combe Lodge, Purley, Park Place, Fawley Court, Cullham Court, Temple House, Harleyford House, Bisham Abbey, Taplow, Cliefden, Cookham, The Willows, Beaumont Lodge, Oatlands, Garrick's Villa and Pope's Villa at Twickenham, Strawberry Hill, Thames-Ditton, Marble-Hill Cottage, the duke of Buccleugh's, lord viscount Sidmouth's, and Mr. Keen's at Richmond, Keppel House, Sion House, Brandenburgh House, and Ingreffs. Among the numerous bridges which cross this national river, the following are justly noted either for their beauty or extent. The first stone bridge on its course is at Ensham, and the next at Lechlade; Oxford, Abingdon, Shillingford, Wallingford, Caversham, Henley, Maidenhead, Eton, Staines, Walton, Kingston, Richmond, Kew, Fulham, Battersea, Vauxhall, (finished 1816,) Westminster, the Waterloo and Southwark (now erecting from designs by that scientific engineer, John Rennie, esq.), Blackfriars, and London. The last six may be said to belong to the metropolis. The jurisdiction of the lord mayor of London over the river Thames, extends from Coln-Ditch, near Stains, to Yendal or Yenlech, near Sheerness, and also includes parts of the rivers Lea and Medway. A very interesting account of the scenery and various objects on this river, with numerous beautiful etchings by

W. B. Cooke, and George Cooke, is published in a work in 2 vols. entitled "The Thames, or Graphic Illustrations of Seats, Villas, &c. on the Banks of that noble River." See also an account of the "Police of the River Thames," by P. Colquhoun, esq. a magistrate of London; 8vo. 1800; and Skrine's "Account of Rivers of Note in Great Britain," 8vo. 1801. S. Ireland published "Picturesque Views on the River Thames," 2 vols. imp. 8vo. Boydell also published a work in 2 vols. folio, consisting of history and description by Dr. Combe, and views from drawings by Farringdon.

Under the word CANAL will be found an ample account of the commerce and navigation of this river, divided under the heads of THAMES RIVER (*lower part*); THAMES RIVER (*middle part*); THAMES and ISIS NAVIGATION; THAMES and MEDWAY CANAL; and THAMES and SEVERN CANAL.

THAMES, a river of New Zealand. Capt. Cook, Mr. (now Sir Joseph) Banks, and Dr. Solander, sailed up this river in a pinnace; at about fourteen miles from the entrance, it is as wide as the Thames at Greenwich, and the tide at flood is as strong; it is not quite so deep, but has water enough for vessels of more than a middle size, and a bottom of mud so soft, that nothing could take damage by running ashore. The course is from south to north, and the entrance between Cape Colville and Point Rodney.—Also, a river of Upper Canada, which runs into lake St. Clair, N. lat. 42° 45'. W. long. 82° 10'.—Also, a river of Connecticut, which runs into the sea, 4 miles below New London.

THAMESIS, called *Jamissa* by Ptolemy, in *Ancient Geography*, a river of the isle of Albion. See THAMES.

THAMETHIS, a town of Egypt. See DAMIETTA.

THAMMUZ, in *Mythology*, is a name under which the Phœnicians worshipped Adonis or Osiris.

THAMMUZ, in *Chronology*, a name given by the Jews to the tenth month of the civil year, containing twenty-nine days, and answering to our June.

THAMNA, in *Ancient Geography*, a celebrated town of Palestine, on the road from Diospolis to Jerusalem. It was the capital of the Thamnitic toparchy.

THAMNATH-SAAR, a town of Palestine, in Samaria, in the tribe and upon the mount of Ephraim, N. of mount Gaas. This town was built by Joshua, and his tomb was there in the time of Jerome.

THAMNERIA, a town of Asia, in Media, in the neighbourhood of the country belonging to the Cadusii. Xenophon.

THAMNIUM, in *Botany*, *εαπνον*, a little shrubby, from *θαμνος*, a shrub, a name chosen by Ventenat, in his *Tableau du Regne Végétal*, v. 2. 35, for the shrubby kinds of Lichen, of which he makes a genus. Its character is

Stems branched in the form of a shrub. Tubercles fungous, coloured.

Lichen rangiferinus, and *L. Roccella*, are mentioned as species of this genus, which is now, like the rest of the author's labours in this department, disregarded, the whole tribe having been so much better studied and arranged by Acharius. See LICHENES.

THAMNOCHORTUS, so called by Bergius, from *θαμνος*, a shrub, and *χορτη*, a grass, alluding to the hard shrubby habit, and natural affinity, of the plant. Berg. Cap. 353. t. 5. f. 8. This genus is now sunk in RESTIO (see that article); and the particular species is *R. scariosus* of Thunb. Prodr. 15, and Willd. Sp. Pl. v. 4. 723, though those authors have used *Thamnochortus* as the specific name of another plant, immediately preceding this in Willdenow, who enumerates thirty species of *Restio*.

THAMSBRUCK, or THOMASBRUCK, in *Geography*, a town of Saxony, in Thuringia; 8 miles S. E. of Mulhausen. N. lat. 51° 5'. E. long. 16° 42'.

THAMUNDACANA, in *Ancient Geography*, a town of Asia, in Interior Libya, S. of the river Niger. Ptol.

THAMYRIS, a town of Mœsia, near the Danube. It was built, according to Jornandes, by Thamyris, queen of the Getæ.

THAMYRIS, in *Mythology*, called by Homer *Κηρυμνη*, one who plays on the cithara, was the son of Philammon. (See his article.) Plutarch, in his Dialogue on Music, tells us that Thamyris was born in Thrace, the country of Orpheus, and had the sweetest and most sonorous voice of any bard of his time. Homer, in his catalogue of ships, where he speaks of the cities under the dominion of Nestor, mentions Dorion as the place where Thamyris contended with the Muses, whom he had the arrogance to challenge to a trial of skill in poetry and music. The conditions and consequences of this contention are fully described by the poet.

“ And Dorion, fam'd for Thamyris' disgrace,
Superior once of all the tuneful race,
Till, vain of mortals empty praise, he strove
To match the seed of cloud-compelling Jove!
Too daring bard! whose unsuccessful pride
Th' immortal Muses in their art defy'd:
Th' avenging Muses of the light of day
Depriv'd his eyes, and snatch'd his voice away;
No more his heav'nly voice was heard to sing,
His hand no more awak'd the silver string.”

Iliad, book ii.

Homer availed himself of the popular story concerning the blindness of Thamyris, and embellished it by his versification. Probably the whole allegory of this blindness had its rise from his having injured the organ of sight by too intense an application to the study of music and poetry. And it is the opinion of Pausanias, that there was no other difference between his misfortune and that of Homer, than that Thamyris was wholly silenced by it, and Homer, without being discouraged, continued his poetical and musical occupation long after his blindness.

THAN, in *Geography*, a town of Hindoostan, in Guzerat; 55 miles N. N. E. of Junagur.

THANÆ, in *Ancient Geography*, a town of Palestine, in the half-tribe of Manasseh, on this side of Jordan.

THANE, or THAIN, *Thanus*, the name of an ancient dignity among the English, or Anglo-Saxons.

Skene makes thane to have been a dignity equal with that of the son of an earl: Camden will have it, that thanes were only dignified by the offices which they bore.

There were two kinds or orders of thanes; the *king's* thanes, and the *ordinary* thanes. The first were those who attended our English-Saxon kings in their courts, and who held lands immediately of the king: whence, in *Domesday-book*, they are promiscuously called *thani*, and *servientes regis*.

Soon after the Conquest this name was disused; and instead of it, they were called the *king's barons*, *barones regis*.

Their origin is referred to king Canutus, who, taking the chief of the Danish nobility, to the number of three thousand, for his guard, and arming them with battle-axes and sabres with gilt handles, called them *thing lith*, from the two Danish words *thing* or *thein*, *body of nobility*, and *lith*, *order of battle*.

The *ordinary* thanes, or *thani minores*, were the lords of manors, who had particular jurisdiction within their limits, and over their own tenants.

These changed their name for that of barons; and hence their courts are called *courts baron* to this day.

In old authors, charters, &c. we also meet with thane as signifying

signifying a nobleman; though sometimes only a freeman, and sometimes a magistrate.

THANE *Lands*, were lands granted by charter of the Saxon kings to their thanes.

THANET, *Isle of*, in *Geography*, is a tract of land on the southern coast of the county of Kent, England, consisting of about 27,000 acres, and is separated from the remaining part of the county by the narrow channel of the river Stour, and the smaller stream called the Nethergong. The marshes which border these streams are extensive, and afford rich pasturage for cattle, but the higher grounds are principally appropriated to the growth of corn. The isle is in shape a long oval, being about nine miles in length from east to west, and nearly five miles broad from north to south. Solinus, who is quoted by Camden, calls it Athanatos, and in some copies Thanatos, which probably gave origin to the Saxon appellation Tenet, or Tanetland; though Lewis derives this from Tene, a fire or beacon; and he supposes the isle to have been so named on account of the beacons or fires which were kept here to give notice of Danish or other pirates, to whose ravages it was greatly exposed. Thanet is bounded on the north and east sides by the ocean; a circumstance which, connected with the salubrity of its air, and its convenient distance from the metropolis, has led to the establishment of several watering-places; and these, in the summer and autumnal seasons, occasion a continual influx of visitants, whose expenditure adds greatly to the wealth of the fixed inhabitants. The chalk cliffs which surround the coast abound in fossils; and among them, the cornua ammonis has been found, measuring upwards of three feet in diameter. The whole of Thanet is divided into the two capital manors of Minster and Monkton, by St. Mildred's Lynch, a narrow strip of land, left unploughed, and extending quite across the isle, from Westgate by Woodchurch, to Sheriff's Hope near Monkton. The isle anciently contained eleven parishes; but those of Sarre and All Saints have been united to St. Nicholas, and that of Woodchurch to Birchington. The parishes of Minster, Monkton, and Stonar, with parts of those of St. Nicholas and St. Lawrence, are under the jurisdiction of two constables; the other parishes, namely St. John's, including the town of Margate; Birchington, with Gore's End, St. Peter's, and Wood or Woodchurch, the ville of Ramsgate, and the ville of Sarre, with the remainder of St. Nicholas and St. Lawrence, are all members of, and subject to the controul of the ports of Dover and Sandwich. The population return of the year 1811 stated the inhabitants of the isle to be 16,156; the number of houses 3209. (See MARGATE, RAMSGATE, and RECVLVER.)—*Beauties of England and Wales*, vol. xiii. Kent; by E. W. Brayley.

THANN, or **DANN**, a town of France, in the department of the Upper Rhine; 13 miles N.N.E. of Befort.

THANN. See **TANNA**.

THANNHAUSEN, or **TANNHAUSEN**, a town of Germany, in the circle of Swabia, and principal place of a lordship of the same name, on the river Mindel; 14 miles N. of Mindelheim.

THANNURIS, in *Ancient Geography*, a town of Asia, in Osrhoene; and another in Mesopotamia.

THANTIA, a town of Palestine, in Batanæa, eastward towards the mountains, S.E. of Adraa.

THANWALD, in *Geography*, a town of Silesia, in the principality of Breslau; 13 miles N.W. of Breslau.

THAOUAOUIS. See **TAVAVIS**.

THAPUA, in *Ancient Geography*, a town situated in the interior of Arabia Felix. Ptol.

VOL. XXXV.

THAPSA, a town of Palestine, in the tribe of Ephraim.

THAPSACUS, or **AMPHIPOLIS**, a large and flourishing town of Asia, in Syria, on the banks of the Euphrates. When Alexander, after leaving Egypt, came to Thapsacus, he found here two bridges over the Euphrates. Xenophon tells us that Cyrus sojourned here five days; and that it was here that he informed the Greeks of his intention to march to Babylon. The soldiers mutinied, but were afterwards appeased by his promises. Thapsacus is now a village, called "El-Der." The channel of the river is here about half a mile in breadth, and would appear to have been fordable from the earliest times to the present day. It was passed on foot by Cyrus and his whole army, and, as some say, by that of Alexander the Great.

THAPSIA, in *Botany*, a name adopted from the ancient Greeks, whose $\theta\alpha\psi\iota\alpha$, if not precisely a species of our present genus, was certainly, like it, a large umbelliferous plant, yielding a gummy exudation, and bearing yellow flowers, succeeded by broad seeds. Such is the description given by Dioscorides, who moreover adds, that his $\theta\alpha\psi\iota\alpha$, so named from the island of Thapsos, where it grew, was in every respect like *Ferula*, but with a more slender stem, and leaves nearly akin to fennel. The root was large; white within, black on the outside, with a thick acrid bark. He attributes various virtues to its gum or juice, either taken as a purge, in oppressions of the chest; or applied externally, along with honey, wax, or frankincense, for cutaneous complaints, tumours, &c.—Linn. Gen. 144. Schreb. 193. Willd. Sp. Pl. v. 1. 1464. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 156. Sm. Prodr. Fl. Græc. Sibth. v. 1. 201. Juss. 220. Tourn. t. 171. Lamarck Illust. t. 206. Gært. t. 21.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbellifera*, Juss.

Gen. Ch. *General Umbel* large, with about twenty rays, of nearly equal length; *partial* of as many, nearly equal, rays. *Involucrum* none, neither *general* nor *partial*. *Pericanth* scarcely discernible. *Cor.* *Universal* uniform; all the flowers fertile; *partial* of five lanceolate incurved petals. *Stam.* Filaments five, capillary, the length of the corolla; anthers simple. *Pistl.* Germen inferior, oblong; styles two, short; stigmas obtuse. *Peric.* Fruit oblong, encompassed longitudinally with a membranous border, separable into two parts. *Seeds* two, very large, oblong, convex, pointed at each end, encompassed at each side with a large, flat, entire-edged border, which is emarginate at each extremity.

Ess. Ch. *Involucrum* neither general nor partial. Fruit oblong, encompassed with a membranous border. Petals uniform, lanceolate, inflexed. Flowers all fertile.

1. *Th. villosa*. Villous Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 1. Ait. n. 1. (Th. prima; Clus. Hist. v. 2. 192. Th. latifolia Clusii; Ger. Em. 1030.)—Leaflets toothed, villous; confluent at the base.—Native of stony ground, in Spain, Portugal, and the south of France. Dr. Sibthorp found it in the fields of Patmos and Cyprus, and Dr. Broussonet at Algiers. The root is perennial, tap-shaped, said to be of an extremely fetid, acrid, and nauseous quality, which has given rise to the English name. Gerard applies to this species what Dioscorides says of *T. garganica*, that exhalations from the root or plant exulcerate the skin. The stem is three or four feet high, erect, round, smooth, leafy, branched at the top. Leaves large and spreading, twice or thrice pinnate; their leaflets sessile, obtuse, pinnatifid, notched, confluent at the base, in the manner of a fern; hairy on both sides; whitish and downy at the back. Umbels several, stalked, terminal, large, smooth, naked. Flowers yellow, rather small. Fruit about half an inch long, and a quarter broad, with four ribs at

each side, and a thin, brown, membranous double wing at each margin.

2. *Th. fetida*. Stinking, Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 2. Ait. n. 2. (*Th. vulgaris*; Ger. Em. 1031. *Th. vulgaris*, carotæ effigie; Lob. Ic. 780. Morif. sect. 9. t. 18. f. 7.)—Leaflets many-cleft, acute; contracted at the base.—Native of Spain, as well as of Zante and Cyprus. Gerarde had this plant in his garden, and it is still, like the foregoing, to be seen in curious botanical collections, though not very commonly. It differs from the *villosa* in having more finely, acutely, and deeply divided leaflets, which are wedge-shaped, not dilated at the base. The size of the whole plant is smaller, and the stem more branched.

3. *Th. Asclepium*. Fine-leaved Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 3. Sm. Fl. Græc. Sibth. t. 286, unpubl. (*Th. apula, foliis millefolii*; Morif. sect. 9. t. 18. f. 9. *Panax Asclepium* Dioscoridis et aliorum, gummiferum; Column. Ecphr. p. 1. 87. t. 86.)—Leaves digitate; leaflets doubly pinnate, in many bristle-shaped segments.—Native of the south of Italy, and of the Levant; unknown in our gardens. Dr. Sibthorp met with this plant in Greece, Rhodes, and near Constantinople. The root is tapering, perennial, brown, gummy, crowned with bristly fibres. Stem solitary, erect, a yard high, slightly branched, round, smooth, the thickness of a goose-quill, almost destitute of foliage, except about the bottom. Leaves on long stalks, of five principal unequal leaflets, radiating from the base, which are doubly, or almost triply, pinnate, their small leaflets being divided very deeply into fine acute segments, one-eighth of an inch long, smooth, and of a bright green. Flowers yellow, in spreading long-stalked umbels. Petals dilated at the base, so as to be, from the inflexion of the point, almost heart-shaped. Seeds with broad, linear, obtuse wings.

4. *T. garganica*. Garganian, or rather Greek, Deadly Carrot. Linn. Mant. 57. Willd. n. 4. Ait. n. 3. Gouan. Illustr. 18. t. 10. Sm. Fl. Græc. Sibth. t. 287, unpubl. (*Th. thaliæri folio*; Magn. Monsp. 287. t. 286. *Th. five Turbith garganicum, semine latissimo*; Bauh. Hist. v. 3. p. 2. 50.)—Leaves radiato-pinnate; leaflets deeply pinnatifid, with linear decurrent segments. Native of Barbary, the south of Italy, and the Levant. Dr. Sibthorp finding it very common throughout Greece, and the neighbouring islands, justly concluded this species to be the true *θαλασσί* of Dioscorides, with whose description it agrees better than any of the rest. It is a stately perennial plant, whose seeds were probably obtained from the garden of Montpellier, by our British cultivators, towards the year 1680. The firm round leafy stem, as well as the sheathing bases of the footstalks, and the ripening seeds, are tinged with a fine glaucous purple. Leaves large, deep green; smooth above; glaucous, and sometimes hairy, below; their segments near an inch long, linear, entire. Common footstalks long, round, sometimes very hairy. Umbels very large, yellow. Petals lanceolate, involute. Fruit an inch long, with broad, shining, brown wings; its sides finely ribbed.

For *Th. trifoliata*, Linn. Sp. Pl. 376, see SMYRNIUM n. 6, cordatum.

Th. polygama, Desfont. Atlant. v. 1. 261. t. 75. Mart. Mill. Dict. n. 6, found on the sea-coast of Barbary, cannot belong to this genus, having a general, as well as partial, involucre, and abortive central flowers. It should seem to be a LASERPITIUM. See that article.

THAPSIS, in *Ancient Geography*, a river of Scythia, in the environs of the Palus Mæotides, according to Dioscorus Siculus.

THAPSOS, in the *Materia Medica of the Ancients*, a name given to a kind of wood of a pale yellow colour, used of old in dyeing of linen and woollen cloths. The Greek *Thapsos* signifies a pale dead yellow colour, and is applicable either to the substance, or the juice or tincture of all these.

The people of Crete at this time use the lycium-wood in dyeing a yellow colour, and it is probable that the *thapsos* was this very tree. Dioscorides tells us, that the wood of this tree was also used in his time to tinge the hair yellow, which was a favourite colour with the Greeks. The lycium is of a colour somewhat deeper than our box-wood, and parts with its stain so easily, that it seems very proper for such a purpose.

THAPSUM, among the old *Roman Writers*, a common name for the verbascum, or mullein; but as there were many other plants, very different in their nature, yet whose names resembled this; such as the *thapsia*, or deadly carrot, and the *thapsum* or *genistella tinctoria*; it was soon found necessary to add some other name, and it was then called *thapsum barbatum*, or *barbassum*.

The reason of the *genistella* being called *thapsum*, was, that its flowers were yellow, and were used to colour the ladies' hair; that being the favourite colour of those days. The flowers of mullein are yellow, and seem more fit for the colouring of the hair than those of the *genistella*; their colour being more easily separated, and continuing on so well, that the glovers of many parts of England use them in the season for colouring their yellow gloves.

It is probable, that the ladies of old used this, as well as the *genistella*, for this purpose: and it might hence obtain the common name *thapsum*. The other part of its distinction, *barbatum*, seems owing to the leaves being so coloured with a woolly down that they look bearded. And when this word is written *barbassum*, it may probably be given as the name of some of those species of mullein which are not hairy, as our black or sage-leaved mullein, and be a corruption of the word *verbascum*. This black mullein has no less title than the white or bearded kind to the name *thapsum*; its flowers being of a yet finer yellow than those of that kind, and being as fit for the use of staining. The glovers in some places use this species for their leather-gloves.

THAPSUS, DEMASS, in *Ancient Geography*, a maritime town of Africa, upon a tongue of low land, S. of the Lesser Leptis. The place abounds with ruins.

THAPSUS, or *Tapsus*, in *Botany*, see VERBASCUM. This name seems to have originated with Gerarde, who gives no explanation, nor do we find any authority for the opinion of De Theis, that it alludes to the isle of Thapsos, as the native country of the plant. Such indeed is the acknowledged derivation of THAPSIA, see that article; with which this *Verbascum*, a *θαλασσί* of the Greeks, has no relationship whatever.

THAR, in *Ancient Geography*, a town of Arabia Felix, belonging to the people called Themi.

THARAND, in *Geography*, a town of Germany, in the circle of Upper Saxony, and circle of Erzgebürg; 10 miles E.N.E. of Freyburg.

THARE, in *Ancient Geography*, a place of the encampment of the Israelites, whence they went to Methea. (Numb. xxxiii. 27.) Thare, situated in Arabia Deserta, was the 24th station of the Israelites.

THARELA, a town of Palestine, in the tribe of Benjamin.

THARGELIA, *Θαργηλια*, in *Antiquity*, an Athenian festival in honour of the sun, and his attendants, the

Hours:

Hours: or, as others think, of the Delian Apollo and Diana. For an account of the ceremonies of this solemnity, see Potter Archæol. Græc. lib. ii. cap. 20. tom. i. p. 400. seq.

THARGELION, *Θαργηλιών*, in *Chronology*, the eleventh month of the Athenian year. It contained thirty days, and answered to the latter part of our April, and the beginning of May.

It took its name from the festival Thargelia, kept in it.

THARNAU, in *Geography*, a town of Silesia, in the principality of Neisse; 1 mile N. of Grotkau.

THARO, in *Ancient Geography*, an island, situated, according to Ptolemy, in the Persian gulf.

THARPA, a town of India, beyond the Ganges, in the Golden Chersonesus. Ptolemy.

THARRANA, a town of India, beyond the Ganges, on the coast of the Great gulf. Ptol.

THARSIA, a town of Africa propria, or one of those which Ptolemy points out between Bagradas and the town of Thabraca.

THARSIS, *Θιαρσισ*, or *Tarshish*. See **OPHIR**.

THASO, in *Geography*, an island of the Grecian Archipelago, situated in the gulf of Contesa, anciently called *Æria*, or *Æthria*, being famous, even to a proverb, for its rich gold-mines. It has a town or village of the same name. N. lat. 40° 34'. E. long. 42° 30'.

THASSUS, *Θηασσος*, or *Thasus*, in *Ancient Geography*, an island situated on the coast of Thrace, opposite to the mouth of the river Nestus. Thasus, son of Agenor, king of the Phœnicians, is said to have remained many years in this island, to have peopled it, and to have given it his name. It was afterwards increased by a Greek colony. The Athenians made themselves masters of this island, and treated the inhabitants with great rigour; but they were expelled by the Macedonians, and these again by the Romans.

THATCH, in *Rural Economy*, prepared straw which is intended to be laid on the top of a building, rick, &c. to keep out the wet. There are many different sorts of materials that may be made use of as thatch, but those which are most commonly employed are the straw of different sorts of grain, as wheat, rye, &c. reed, stubble, heather, &c. The straw of wheat and rye, when well prepared and laid, probably forms the neatest and most secure covering for general purposes. It has indeed been stated, that the most suitable material for the purpose is that of good wheat-straw that has been much bruised in threshing out the grain. But when this cannot be had in sufficient quantity, rye-straw may be substituted in its place; however, from its rough and stubborn quality, it is neither so neat in its appearance, so durable, nor affords so secure a covering. And that barley and oat straw are sometimes made use of for the purpose, but they form very indifferent coverings, and such as are not by any means lasting. The former, when strong, is however preferable to the latter.

The reed is a highly valuable article for the purpose of thatch, where a lasting roof is required; but is much too expensive and stubborn for common purposes. It has been remarked by Mr. Marshall, in the *Rural Economy of Norfolk*, that there, the favourite material for roofs, and that which is the most eligible after good slate for farm purposes, is reed. And that a reed roof properly laid, will lie fifty years without touching; and thirty or forty more, with only adjusting (driving) it, and levelling the hollows with a little fresh reed. At an hundred years old it may be relaid; and will then, if laid upon the upper parts of the roof, last through a considerable part of another century. The reed is, he says, principally cut from the margins of

the *broads*, (large pieces of water,) and is carried, perhaps, forty or fifty miles into the central and northern parts of the county. And it is added, that though a covering of reed is, in the first instance, costly; when its durability, and the high degree of preservation in which it keeps the roof, are taken into the account, it is of all other the cheapest covering; besides its being, whether in the extreme of heat or cold, the most comfortable.

And it is stated, that the price of reed, in the place of its growth, is from three pounds to three guineas a hundred, containing six score fathoms; each fathom (composed of five or six sheaves) measuring six feet in circumference. A hundred of reed will cover five squares of roof: the laying is a halfpenny a yard, or four shillings and twopence a square; and the tar rope and rods for fastening it on cost eighteen pence a square: so that a covering of new reed costs about eighteen shillings a square, containing 100 square feet; besides carriage, and what is called *roofing*; namely, a cap of wheat-straw placed upon the ridge, in a somewhat similar manner, and for the same purpose, as ridge-tiles are put on. This capping, which is done in a most effectual, but in a tedious and expensive manner, costs, in materials and workmanship, about sixteen pence each foot in length: which, upon a roof of sixteen feet and a half spar, is an additional expence of four shillings each square of reeding.

With regard to the carriage, it is in proportion to the distance. Taking twenty miles as a medium distance, and one shilling a mile as a medium price; the expence is, he says, twenty shillings a 'load' of sixty fathoms, or forty shillings a hundred; which laying five squares is a further addition of eight shillings a square: therefore, the whole expence of a covering of reed fetched twenty miles, may, he supposes, be laid at thirty shillings a square. The writer has been thus minute, he says, in his account of this material, as it has been much overlooked in other districts, where it may be found useful.

This material is a great deal more expensive in every respect which has any relation to this object, at the present time, than it was then.

And with respect to the stubble, it is said to be a material that may be made use of with propriety and advantage in some situations. This is the stubble of such wheat or other crops as have been cut at a great height; which, after being mown close to the ground and raked up, serves this purpose, especially for the more common purposes of the farm, such as covering hay and straw stacks, &c. the thatching potatoes when hogged in the ground, and many other such cases.

The last material, heather, is also found a highly valuable article for the purpose of thatch in districts where it grows in abundance, as it is extremely durable. See **HEATHER**.

The thatch which is removed from the stacks or buildings may be used as a litter for various purposes.

The modes of preparing and applying these different matters to the roofs of stacks and buildings will be pointed out in speaking of the operation of securing such roofs by means of such substances. See **THATCHING**.

Where straw of the rye or wheat kind is very strong, it is often termed *reed* or *straw reed* by the thatcher, and used for covering large hay-stacks very commonly in many districts.

THATCHAM, in *Geography*, a village and parish in the hundred of Reading and county of Berks, England, is situated 3 miles E. from Newbury, and 53 miles W. from London. It appears to have been formerly a town of some consequence, from the Domesday Survey, and other re-

cords, in which it is described as an ancient borough; but it does not appear ever to have sent representatives to parliament. From a very early period it had a market on Sundays, which was confirmed to the abbot and convent of Reading by a charter of Henry II. The market-day was changed by Henry III. in 1218 to Thursday; but the market has long been discontinued. Two annual fairs are still held. The manor of Thatcham was given to the abbot and convent of Reading by Henry I. At the dissolution it was granted, in 1539, to John Winchcombe, son of the celebrated Jack of Newbury: it is now the property of William Mount, esq. of Wasing. A charity-school was founded here, in 1707, by lady Frances Winchcombe, who endowed it with 53*l.* per annum. The school had been long discontinued, and its revenue lost to the parish; when Mr. Thompson, a late vicar, instituted a suit for their recovery, and after a long contest succeeded in the re-establishment of the school, with an income for the master increased to 200*l.* per annum; forty boys are now clothed and educated, and six of them annually apprenticed with premiums of 10*l.* each. The parish of Thatcham is the most extensive of any in the county, excepting Lamborn, and includes six townships. The population, according to the parliamentary report of the year 1811, was estimated at 2104; the number of houses at 424.—Lysons's "Magna Britannia," vol. i. Berkshire.

THATCHER, a rock in the English Channel, on the north side of Torbay.

THATCHER, in *Rural Economy*, a person who performs the business of thatching.

THATCHING, the operation of covering the roofs of buildings, stacks, and other things, with some sort of thatch. For this purpose, articles of the straw kind are prepared in the following manner: After being well moistened with water, they are drawn out in handfuls perfectly straight and even into regular lengths, and the short straw separated from them, leaving them placed in convenient ranges for forming bundles to be carried to the thatcher by the person who has the serving of him.

In regard to the application of the thatch to stacks of hay or corn, there are different methods pursued, according to the nature of the materials employed. Where long straw is made use of, the operator or workman usually begins at the eaves or bottom part of the roof, depositing it in handfuls in regular breadths till he reaches the top, the different handfuls being so placed endways as to overlap each other, the upper ends being constantly pushed a little into the bottom parts of the sheaves or other matters. In this manner he gradually proceeds, breadth after breadth, till the whole of the roof is covered, which is usually done to the thickness of about four or five inches. And in order to retain the thatch in its place, short sharp-pointed sticks, termed *prods* in some places, are occasionally thrust in, in a slanting direction upwards; and sometimes small sticks, often called *spelks*, sharpened at the ends, are bent and thrust in along the top parts and sides. But as the water is apt to follow the course of the sticks, it is perhaps a better practice to make use of ropes of twisted straw for this purpose. In some cases, these are applied only round the bottom parts of the roof and the sides; while in others, which is a much better and more secure method, they are applied in such a manner over the whole stacks, as to form a sort of coarse net-work of nine or twelve inches in width in the niches, the ends being well fastened either to belt-ropes passed in suitable directions for the purpose, or to different parts of the straw of the stack.

In the application of stubble as a thatch, it is mostly,

after being prepared, put on by sticking one of its ends into the roof of the stack in a regular and exact manner, so as that it may stand out very close and thick; when the other, with such loose straws as may occur, is to be cut over or pared off, with a very sharp tool for the purpose, so as to form a neat and impenetrable thatch, having the appearance of a newly thatched house roof; the whole being well secured in its place by short pegs made for the purpose, somewhat in the same way as in the thatch of other stacks.

In the thatching of the roofs of houses or other buildings with any of the different sorts of straw, the materials are to be laid on to a considerable thickness, and firmly secured. They are applied in regular narrow slips, or what in some districts are termed *gangs*, from the eaves of the building to the ridges, the ladder being moved forward as the work proceeds. The thatch is secured by short sharpened sticks, as above, thrust in where necessary. And bended sticks, sharpened at each end, are likewise sometimes made use of near the ridges, being thrust in at each end. In finishing the work, the thatcher mostly employs an iron-toothed rake, with which the whole is raked and trimmed over from top to bottom, so as to render it completely smooth and even, and take away all the short straws, and other irregular matters.

The method of thatching with reed, according to Mr. Marshall, in his account of the Rural Economy of Norfolk, is this: no laths being made use of; in laying it, a little of the longest and stoutest of the reed is scattered irregularly across the naked spars, as a foundation to lay the main coat upon: this partial gauze-like covering is called the "fleaking." On this fleaking the main covering is laid, and fastened down to the spars by means of long rods, provincially "sways," laid across the middle of the reed, and tied to the spars with rope-yarn, or with "bramble bonds," formerly much used, but now pretty nearly laid aside. In laying on the reed, the workman begins at the lower corner of the roof, on his right hand, for instance, and keeps an irregular diagonal line, or face, until he reaches the upper corner to his left, a narrow eaves-board being nailed across the feet of the spars, and some fleaking scattered on; the thatcher begins to "set his eaves," by laying a coat of reed, eight or ten inches thick, with the heads resting upon the fleaking, and the butts upon the eaves-board. He then lays on his *sway* (a rod about the size of a small edder) about six or eight inches from the lower point of the reed; whilst his assistant, on the inside, runs a needle, threaded with rope-yarn, close to the spar; and, in this case, close to the upper edge of the eaves-board. The thatcher draws it through on one side of the sway, and enters it again on the contrary side, both of the sway and of the spar: the assistant draws it through, unthreads it, and with the two ends of the yarn makes a knot round the spar; thereby drawing the sway, and consequently the reed, tight down to the roof: whilst the thatcher above, beating the sway and pressing it down, assists in making the work the firmer. The assistant having made good the knot below, he proceeds with another length of thread to the next spar, and so on, till the sway be bound down the whole length; namely, eight or ten feet. This being done, another stratum of reed is laid on upon the first, so as to make the entire coat eighteen or twenty inches thick at the butts; and another sway laid along, and bound down, about twelve inches above the first.

The eaves being thus completely set, they are adjusted and formed, not square with the spars, but nearly horizontal: nor are they formed by cutting, but by "driving" them with a "legget," a tool made of a board eight or nine inches square, with a handle two feet long, fixed upon the back of it,

it, obliquely, in the manner of the tool used by gardeners in beating turf. The face of the legget is set with large-headed nails, to render it rough, and make it lay hold of the butts of the reeds. Then another layer of reed is laid on, and bound down by another sway, somewhat shorter than the last, and placed eighteen or twenty inches above it; and above this another, and another, continuing to shorten the sways, until they be brought off to nothing, and a triangular corner of thatching formed. After this the sways are used their whole length, whatever it happens to be, until the workman arrives at the finishing corner.

In order to give a finish to the ridge, a *cap* (provincially a "roof") of straw is set on in a masterly, but in an expensive manner. In this operation, the workman begins, it is observed, by bringing the roof to an angle, with straw laid the long way upon the ridge, in the manner in which a rick is topt up; and to render it firm, to keep it in its place, and to prevent the wind from blowing it off, or ruffling it, he pegs it down slightly with "double broaches;" namely, cleft twigs, two feet long, and as thick as the finger, sharpened at both ends, bent double, and perhaps with the twisting of the crown, and perhaps barbed, by partial chops on the sides, to make them hold in the better. This done, the workman lays a coat of straight straw, six or eight inches thick, across the ridge; beginning, on either side, at the uppermost butts of the reed, and finishing with straight handfuls evenly across the top of the ridge. Having laid a length of about four feet in this manner, he proceeds to fasten it firmly down, so as to render it proof against wind and rain. This is done by laying a "broachen ligger" (a quarter-cleft rod as thick as the finger, and four feet in length) along the middle of the ridge, pegging it down at every four inches with a double broach, which is first thrust down with the hands, and afterwards driven with the legget, or with a mallet used for this purpose. The middle ligger being firmly laid, the thatcher smooths down the straw with a rake and his hands, about eight or nine inches on one side, and at six inches from the first lays another ligger, and pegs it down with a similar number of double broaches, thus proceeding to smooth the straw, and to fasten on liggers at every six inches, until he reach the bottom of the cap. One side finished, the other is treated in the same manner; and the first length being completed, another and another length is laid, and finished as the first, until the other end of the ridge be reached. He then cuts off the tails of the straw square and neatly with a pair of shears, level with the uppermost butts of the reed; above which the cap (or more properly the *rooflet*) shews an eaves of about six inches thick. And lastly, he sweeps the sides of the main roof with a bow of holly, when the work is completed. This, when well performed, must be a durable and useful mode of thatching, and at the same time one which has a neat appearance.

In thatching with heather, that material mostly undergoes some sort of preparation, so as to render it as equal as possible in size and strength, being laid and fastened upon the roofs then in somewhat the same manner as that of straw. It is afterwards swept, cleaned, and finished off in a neat and exact manner, so as to look extremely well.

In some of the more exposed situations in the northern parts of the island, they have other modes and practices of thatching buildings with straw in use, such as performing it with clay, or thin turf and that material.

If the roof be covered with thin turf or divots, the workman is to twist the upper part of the straw into a sort of knot; then, with a stick prepared for the purpose, to force the knot thus formed either under or through the turves or divots, so that it may have a firm hold of the roof; after

which, to spread the lower part of the bundle of straw nicely on the roof, continuing to do the same to the very top of the roof; and then to clay it all over, and begin another tier, gang, or row of the thatch. In this way, the thatch should not be laid thinner than six inches, and when it is laid eight inches thick, it is the more durable. Thin turf, or divots, were originally thought the best foundation; but it has been since found by experience, that they rot the straw, and that straw alone, when stitched on with rope-yarn, lasts much longer. If straw alone be used in this manner, it will last twenty years; but the straw must be laid on two inches thicker than when clay is added. A roof that is thatched with divots, straw, and clay, in the common way, will last from seventeen to twenty years; and is also capable of being mended without raising any part of the roof that is entire. The above kind of roof is much less liable to catch fire than straw roofs without clay. The clay that answers the purpose best is that which has a due proportion of sand in it. If stiff clay should be used, it will be necessary to add one cart-load of sand to every two of the clay.

This sort of claying may, of course, be useful and advantageous in thatching the roofs of buildings in many situations and places.

THAU, in *Geography*, a lake of France, in the department of the Herault, near the Mediterranean, between Frontignan and Agde.

THAUANA, in *Ancient Geography*, a town situated in the interior of Arabia Felix.

THAUBA, a town in the interior of Arabia Felix. Ptol.

THAUGHTS, or **THOUGHTS**, in a *Boat*, are the benches on which the rowers sit to row.

THAUMASIVS MONS, in *Ancient Geography*, a mountain of Arcadia, N.W. of Mantinea, above the river Moloessus.

THAUMATURGUS, formed from *θαυμαζω*, *wonderful thing*, and *εργον*, *work, worker of miracles*; an appellation which the Romanists gave to several of their saints, eminent for the number and greatness of their miracles.

St. Gregory, called *Thaumaturgus*, or Gregory of Neocæsarea, was a disciple of Origen about the year 223, and afterwards bishop of Cæsarea, in Pontus; and in that capacity he assisted at the first council of Antioch, and at that of Ephesus, against Paulus Samosatenus. St. Leo of Catania is also called *Leo Thaumaturgus*. He lived in the eighth century; and his body is still honoured at Rome, in the church of St. Martin de Tours. St. Francis Paul, and St. Francis Xavier, are the great Thaumaturgi of these last ages.

THAWING, the resolution of ice into its former fluid state, by the warmth of the air.

THAXTED, in *Geography*, an ancient market-town in the hundred of Dunmow, and county of Essex, England, is situated 19 miles N.N.W. from Chelmsford, and 43 miles N.N.E. from London. The town was known in the Saxon times, as the church is recorded to have belonged, in the reign of Edward the Confessor, to the college of St. John Baptist, at Clare, in Suffolk. Thaxted was incorporated by charter of Philip and Mary, which was confirmed by queen Elizabeth; under this the civil government is vested in a mayor, recorder, two bailiffs, and twenty principal burgessees. In the reign of James II. the corporation experienced a temporary suspension; for being served with a writ of quo warranto, the corporate officers, either through fear or poverty, thought fit to retire from their offices. The market was granted by Edward II., but was discontinued for a long period: it has been recently revived, and

is now held on Fridays. Here are also two annual fairs. In the population return of the year 1811, Thaxted was stated to contain 390 houses, occupied by 1733 persons. The church is a very large and beautiful structure, and appears, from the various arms and cognizances on several parts, to have been built at different times in the fourteenth and fifteenth centuries. The whole fabric is embattled, and supported by strong buttresses, terminated by canopied niches, and curiously purfled pinnacles. At the west end is an embattled tower, sustained by buttresses, and surmounted by a neat octagonal spire, rising to the height of 181 feet. The interior consists of a nave, transept, chancel, and side aisles: the arches of the nave are pointed, and supported by eight clustered columns on each side. The expence of the erection of this church was principally defrayed by the noble families of Clare and Mortimer, who then possessed the manor, with some assistance from king Edward IV. A chantry, besides various chapels and altars, were used here before the reformation. The charitable benefactions for the use of the poor inhabitants of Thaxted are considerable. An estate, called Yendleys, deriving its name from Thomas Yendale (who resided on it temp. Henry VI.) was, on his death, vested in trust for his four sons and their issue; and in default of such issue, to be sold for the benefit of the church and poor. The sons all dying childless, the estate was sold 5 Henry VII. and the produce is applied to the support of a school, repairing the church, improving the highways, &c. In 1698, William, lord Maynard, bequeathed 4000*l.* in trust, the produce to be applied for increasing the minister's salary, repairing the church, marrying poor young women, binding out apprentices, and relieving poor people overburthened with children. Among other benefactions are endowments for alms-houses in several parts of the town: one of the buildings appropriated for that purpose is the old chantry-house. The ancient guildhall is now the parish workhouse: the mote-hall is used for a public school.—*Beauties of England and Wales, vol. v. Essex; by J. Britton and E. W. Brayley. Morant's History, &c. of Essex, 2 vols. folio.*

THEA, in *Ancient Geography*, a town of the Peloponnesus, in Laconia.

THEA, in *Botany*, the Tea-tree, a name of barbarous derivation, originating in the Chinese *Tcha*, or Japanese *Tsja*, of which the various nations of Europe have made, according to their fancy, Chaa, Tea, Thé, &c. and which Kæmpfer has formed in Latin into *Thea*. This last has been admitted by Linnæus, for the sake of its Greek orthography, exactly that of *thea*, a goddess, a coincidence highly welcome to those who honour the cordial beverage of tea as it deserves.—*Linn. Gen. 269. Schreb. 361. Willd. Sp. Pl. v. 2. 1180. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 303. Juss. 262. Lamarck Illustr. t. 474. Gært. t. 95.*—Class and order, *Polyandria Monogynia*, Linn. Rather *Monadelphia Polyandria*; see Sm. *Introductio ad Bot. ed. 3. 335. Nat. Ord. Columnifera*, Linn. *Aurantii et Melii affinis*, Juss.

Gen. Ch. *Cal.* Perianth inferior, small, of one leaf, in five deep, rounded, obtuse, permanent segments. *Cor.* of one petal; tube none; limb in six, or more, deep, unequal, rounded, concave, imbricated segments, much longer than the calyx; the outer ones smallest. *Stam.* Filaments numerous, about two hundred, thread-shaped, shorter than the corolla, united at the base into a shallow cup-like tube, inserted into the receptacle, and connected with the bottom of the petal; anthers peltate, simple, nearly globose. *Pist.* Germen superior, globose, with three obtuse angles; style triangular, with three furrows, the length of the stamens, splitting into three parts; stigmas three, linear-oblong, de-

flexed. *Peris.* Capsule three-lobed, three-celled, bursting along the upper side of each lobe. *Seeds* solitary, globose, somewhat angular.

Ess. Ch. Calyx in five deep rounded segments. Corolla in six, or more, deep imbricated segments. Capsule superior, three-lobed. Seeds solitary.

Obf. Gærtner remarks that there are rudiments of four or six seeds in each cell of the germen. The genus is, doubtless, nearly related to *CAMELLIA*, (see that article,) and should stand next to it in the artificial, as well as natural system. Whether the connection of the stamens varies, or whether we have sometimes in our gardens Thunberg's *C. Sasanqua* for the true Tea-plant, is extremely difficult to determine. The flowers in England are certainly never so large as in his plate of *Sasanqua*, which latter may possibly be a species of *Thea*, though very distinct from the Linnæan specimens marked *T. Bohea*, and from all we have ever examined in gardens. Plukenet's Fruticis Theæ species altera Sinarum, Amalth. t. 405. f. 3, may belong to this *Sasanqua*. The species of *Thea* are involved in much obscurity. Linnæus was led to describe two, under the popular names of *Bohea* and *viridis*, which he distinguished by the former having six petals, or rather segments of the corolla, and the latter nine. But for these characters he is indebted to Hill, whose authority is little to be relied on. We have never seen perfect specimens of more than one species, which answers to the definition of the *Bohea*, with scarcely any variation; nor do the leaves of common green or black tea, when expanded by hot water, betray any difference in their ferratures, veins, or other respects, from that or from each other. The *Pekoe*, whose silky young branches are conspicuous in the tea-chest for their whiteness, agrees in that particular with our garden specimens of *Thea*, and not with *Camellia Sasanqua* sent by Thunberg, for this last is hairy in a very different manner. Such being the state of the case, we can undertake to describe only one species of *Thea*.

1. *T. viridis*. Green Tea. Gært. v. 2. 83. t. 95. f. 1. Linn. Sp. Pl. 735. Willd. n. 2. (*T. bohea*; Linn. Sp. Pl. 734. Amœn. Acad. v. 7. 253. t. 4. Willd. n. 1. Ait. n. 1. *Thea*; Kæmpf. Am. Exot. 605. t. 606. Woodv. Med. Bot. suppl. 116. t. 256. *T. chinensis*; Curt. Mag. t. 998. *T. cantoniensis*; Lour. Cochinch. 339. *Thée*; Barth. Act. v. 4. t. 1. Tea-tree; Letson Monogr. t. 1.)—Native of China and Japan. The late Mr. John Ellis is said to have first raised it from seed in England, about the year 1768. The shrub is propagated by cuttings, and will bear our winters with a slight degree of shelter, though it rarely flowers, except in a greenhouse or stove. The stem is from three to six feet high, bushy, with numerous, alternate, round, leafy branches, smooth, except at the very extremity, where the youngest shoots are finely silky, with close-pressed hairs. Leaves alternate, on short, thick, channelled, smooth foot-stalks, evergreen, elliptic-oblong, with a blunt emarginate point, copiously serrated, except at the base, with inflexed pointed ferratures, smooth on both sides, with one rib and many transverse veins, interbranching towards the margin; paler beneath; their length two or three inches; their breadth about one inch: the young ones finely silky before expansion, with a deciduous point. Stipules none. Flowers axillary, or, on the lateral shoots, nearly terminal, white, not unlike those of a Myrtle, but rather larger, and on short, thick, recurved, round, smooth stalks, usually two together, accompanied by a few alternate, short, ovate, deciduous bractæas. The two outer segments of the corolla, smaller than the rest, are green, or purplish, at the back. Anthers and stigmas yellow.

For the economical history of this plant, see TEA. We have

THEA.

have been greatly at a loss for a specific name, and have adopted *viridis* to avoid any needless change, thinking it rather preferable to *Bohea*, which is a partial name, and of corrupt orthography. Dr. Sims, in *Curt. Mag.*, has used *chinensis*, but this is liable to objection, as the name of a country to which the plant is not quite peculiar; and Loureiro's *cantonensis* is therefore still more exceptionable. This last author concurs in the opinion that all the common Chinese teas belong to one species. He describes indeed two others, *T. cochinchinensis*, which seems a trifling variety of the above; and *T. oleosa*, growing wild near Canton, said to bear a yellow berry, whose seeds supply the Chinese with lamp-oil.

THEA, in *Gardening*, furnishes plants of the exotic shrubby kind, the species of which chiefly in use is the tea-tree (thea).

This tree, as it is commonly described, differs in height, in its native climate, from five or six feet to thirty, and even one hundred and fifty, or more, when let grow to its full size and dimensions.

And in respect to the varieties of it, Martyn has considered them all as forming one species, in which he is, he asserts, supported by the best authorities. Kämpfer, he contends, attributes their difference to soil, culture, age of the leaves, and method of curing them. Mr. Ellis also directly asserts, that the green and bohea tea are one and the same species; and that it is the nature of the soil, the culture, and manner of gathering and drying the leaves, that make the difference. So also Sir George Staunton maintains, that every information received concerning the tea plant concurred in affirming, that its qualities depended upon the soil in which it grew, and the age at which the leaves were plucked off the tree, as well as upon the management of them afterwards. See TEA and THEA.

The bohea tea-trees now introduced into many botanic gardens near London, exhibit very obvious varieties: the leaves are of a deeper green colour, and not so deeply serrated; and the stalk is usually of a darker colour: but the botanical characters are the same. Thunberg also distinguishes two varieties from the leaves, which in one are smaller, flat, darker green, with straight serratures, and in the other larger, waved, brighter green, with sinuate serratures: but they can scarcely be considered as distinct species. Loureiro observed little difference in the sou-chong which he examined: both these have a brown colour, but are more odorous and precious than the common bohea of the province Fo-kien, which he had not an opportunity of seeing in a living state, though it is the most common and cheapest of all. He examined the dry flowers of the green-tea from the province of Kiang-si, and observed the same inconsistency as to the number of parts in the calyx and corolla, as in the bohea. Upon the whole, he concludes that all the differences of Chinese tea form only one botanical species, owing their variation to soil, culture, and method of preparation; all retaining the same inconsistency in the parts of the flower, which gave occasion to Linnæus to consider them as two species. Besides, it is evident that many varieties of tea are known in China, which arise from mixture and management.

The distinctions chiefly regarded in Europe are the following.

Green Teas.—1. Bing, imperial or bloom tea, with a large loose leaf, of a light green colour, and a faint delicate smell.

2. Hy-tiann, hikiong, hayfluen or heechun, known to us by the name of hyson tea: the leaves are closely curled

and small, of a green colour verging towards blue. Another hyson tea, with narrow short leaves, is called hyson-utchin. There is also a green tea named globe, with long narrow leaves.

3. Song-lo or singlo, which name it receives, like several others, from the place where it is cultivated.

Bohea Teas.—1. Soo-chuen, fut-chong, fou-chong, or fu-chong, called by the Chinese faa-tyang, and fact-chaon or fy-tyann, is a superior kind of cong-fou tea. It imparts a yellowish-green colour by infusion, and has its name from a place or province in China. Padre futchong has a finer taste and smell: the leaves are large and yellowish, not rolled up, and packed in papers of half a pound each. It is generally conveyed by caravans into Russia: without much care it will be injured at sea. It is rarely to be met with in England.

2. Cam-ho or foun-lo, called after the name of the place where it is gathered: a fragrant tea with a violet smell; its infusion is pale.

3. Cong-fou, congo, or bong-fo: this has a larger leaf than the following, and the infusion is a little deeper coloured. It resembles the common bohea in the colour of the leaf.

There is also a sort called lin-kifam, with narrow rough leaves. It is seldom used alone, but mixed with other kinds. By adding it to congo, the Chinese sometimes make a kind of pekoe tea.

4. Pekao, pekko, or pekoe, by the Chinese called back-ho or pack-ho: it is known by having the appearance of small white flowers intermixed with it.

5. Common bohea or black tea, called moji or mo-ee by the Chinese, consists of leaves of one colour. The best is named Tao-kyonn. An inferior kind is called An-kai, from a place of that name. In the district of Honam, near Canton, the tea is very coarse, the leaves yellow or brownish, and the taste the least agreeable of any. By the Chinese it is named honam-te, or kuli-te.

But besides these, tea, both bohea and green, is sometimes imported in balls, from two ounces to the size of a nutmeg and of peas. The Chinese call it poncul-tcha. The smallest in this form is well known under the name of gunpowder tea.

And sometimes the succulent leaves are twisted like pack-thread, an inch and a half, or two inches long; three of these are usually tied together at the ends by different coloured silk threads. Both green and bohea teas are prepared in this manner.

The manner of gathering and preparing the leaves, as practised in Japan, according to Kämpfer, as far as our information reaches, is in a great measure conformable to the method used by the Chinese. See TEA.

Whether the Chinese collect the tea precisely at the same seasons as in Japan, we are not well informed; but most probably the tea harvest is nearly at the same periods, the natives having frequent intercourse, and their commercial concerns with each other being very extensive.

For an account of the preparation of the tea-leaves, &c. see TEA.

The country people cure their tea-leaves in earthen kettles, which answer every necessary purpose, at less trouble and expence than by the process described under the article TEA, and they are thus enabled to sell them cheaper. After the tea has been kept for some months, it is taken out of the vessels in which it was stored, and dried again over a very gentle fire, that it may be deprived of any humidity which remained, or it might have since contracted.

The common tea is kept in earthen pots with narrow mouths; but the best sorts, used by the emperor and nobility, is put into porcelain or china vessels. The coarsest tea is kept by the country people in straw baskets, made in the shape of barrels, which they place under the roofs of their houses, near the hole that lets out the smoke.

Method of Culture.—These plants may be raised in this country by seeds, layers, and cuttings of the young branches. The editor of Miller's Dictionary advises that the seeds should be procured from China, and that care should be taken that they be fresh, sound, ripe, white, plump, and moist internally. After being well dried in the sun, they may be inclosed in bees-wax, or, left in their capsules, they may be put into very close canisters of tin or tutenague. Thouin, in his directions to Perouse, it is said, recommends these and other seeds to be placed in alternate layers of earth or sand, in tin boxes, closed up exactly, and placed in solid cases, covered with waxed cloth; the boxes to be placed in a part of the ship the least accessible to moisture, and the most sheltered from extreme heat or cold. And Mr. Sneyd, it is added, was very successful in having seeds packed up in absorbent paper, and surrounded by raisins or moist sugar, which kept them in a state fit for vegetation. American seeds are frequently brought over, by putting them into a box, not made too close, upon alternate layers of moss, in such a manner as to admit the seeds to vegetate. This might be tried with the seeds of the tea-tree; and to succeed more certainly, some of the seeds might be sown in pots or boxes, when the vessel arrives at St. Helena, and after passing the tropic of Cancer, near the latitude of thirty degrees north. But the best method seems to be, to sow ripe seeds in good light earth in boxes, at leaving Canton, covering them with wire, to prevent rats and other vermin from getting to them; and taking care that the boxes be not exposed to too much air, nor to the spray of the sea. A little fresh or rain-water should be sprinkled over them now and then; and when the seedling plants appear, they should be kept moist and out of the burning sun. If young plants can be procured in China, they may be sent over in a growing state in boxes, forty inches long by twenty broad, and as much in depth, having a few holes bored through the bottom. When the trees arrive here, they must be kept in a greenhouse during the winter, and in the open air during the summer; and if they come in bad condition, it may not be amiss to plunge the pots into which they are transplanted in a gentle hot-bed, or to set them in a tan-pit, to make them strike and shoot more freely. It is further remarked, that though the tea-tree will not at present bear the rigour of our winters in the open air, yet it is not impossible but it may gradually become naturalized to our climate, like the magnolia, among several other trees and shrubs; especially if it were to be brought from the coldest provinces of China, where it grows, or from the parts of Europe a little to the southward of us, when it has been naturalized there. It is increased freely from cuttings, when managed in the same manner as gardenias: and it also sometimes grows from layers laid down in the autumn or spring.

Some of these plants should be always kept in pots, to be removed under the shelter either of a greenhouse, glass case, or deep garden frame, in winter; and others be planted in a dry, well-sheltered, warm, conspicuous part of the shrubbery, to be afforded occasional covering from rigorous frosts.

They afford variety in greenhouse collections, as well as in the shrubberies.

Although in this country, plants of this kind are only cultivated for the purpose of curiosity, variety, and diversity among greenhouse and other collections, in small quantities; in China, where they are natives, they are raised in vast abundance in plantations of very great extent for their leaves, which form a great and valuable article of merchandize to that country for the supply of England and most other parts of Europe, they being employed, in their different prepared states, for the making of an infusion with boiling water, which is called tea, and which is very generally in use, especially in this and some other countries. For other particulars, see TEA.

THEAK, in *Rural Economy*, a word provincially used to signify thatch.

THEAKIKI, in *Geography*, a river of North America, which runs into lake Illinois, N. lat. 40° 52'. W. long. 89° 15'.

THEAME, in *Ancient Geography*, a town of Asia, in Babylonia, on the confines of Arabia Deserta. Ptol.

THEANDRIC, Θεανδρικός, *dei-virile*; a term signifying divine and human, formed from Θεός, *God*, and ανθρωπος, *man*.

St. Dionysius, bishop of Athens, first used the word *theandric*, to express a double operation, or two operations united in Jesus Christ; the one divine, the other human. The Monophysites afterwards abused it, to signify the one only operation which they admitted in Jesus Christ; in whom they believed there was a mixture of the divine and human nature, whence resulted a third nature, which was a compound of the one and the other, whose operations followed the essence and qualities of the mixture, and were neither divine nor human, both at once, or, in one word, *theandric*.

Θεανδρική ενεργεια, *theandric*, or *dei-virile* operation, in the sense of Dionysius and Damascenus, is thus exemplified by Athanasius. When Christ healed the person who was born blind, the spittle he voided was human, but the opening of the eyes was done by his divine power. And thus, in raising Lazarus, he called as man, but awaked him from the dead as God.

The term *theandric*, and the dogma of *theandric* operations, were examined with great care and attention, at the council of Lateran, held in 649, where pope Martin solidly refuted the notion of *theandric* operations, and shewed, that the sense in which St. Dionysius first used the word was Catholic, and quite remote from that of the Monophysites and Monothelites.

THEANGELA, in *Ancient Geography*, a town of Asia Minor, in Caria.

THEANO, or TEANO, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Lavora; the see of a bishop, suffragan of Capua; 15 miles N. of Capua.

THEANTHROPOS, Θεανθρωπος, formed from Θεός, *God*, and ανθρωπος, *man*, denominated *God-man*; a term sometimes used in the schools to signify Jesus Christ, who was regarded as *God-man*; or represented by some scholastic theological writers, as comprehending two natures in one person.

THEANUM, in *Ancient Geography*, a town of Italy, in Campania, upon the Latin way, S.E. of Casinum. See THEANO.—Also, a river of Italy.

THEATER, or THEATRE, *Theatrum*, formed from θεατρον, *spectacle*, of θεαομαι, *I see*, among the *Ancients*, a public edifice, for the exhibition of scenic spectacles or shows to the people.

Under the word *theater* was comprehended, not only the eminence on which the actors appeared, and the action passed,

passed, but also the whole area or extent of the place, common to the actors and spectators.

In this sense, the theater was a building encompassed with porticoes, and furnished with seats of stone, disposed in semicircles, ascending gradually over one another; which encompassed a space called the *orchestra*, in the front of which was the proscenium, or pulpitum, on which the actors performed, and which is what we distinctly call the theater, or stage. The proscenium was divided into two parts; the one higher, on which the actors declaimed, and the other lower, on which the chorus was commonly placed. This latter was raised ten or twelve feet above the pit, from which there was an ascent to it; and thus situated, the chorus might easily turn either towards the actors or towards the spectators.

On the proscenium stood the *scena*, a large front, adorned with orders of architecture, behind which was the post-scenium, or places where the actors made themselves ready, retired, &c. So that the *scena*, in its full extent, comprehended all the part belonging to the actors. In the first ages of the Roman commonwealth, theaters were only temporary, and formed of wood: the most celebrated of these was that of M. Scavrus, mentioned by Pliny. The first fixed theater was erected by Pompey the Great, who built it very magnificently with square stone.

In the Greek theaters, the *orchestra* made a part of the *scena*, but in the Roman theaters, none of the actors ever descended into the *orchestra*; which was taken up by the seats of the senators.

The most celebrated theaters remaining of antiquity, are the theater of Marcellus, and that of Pompey; which are also called *amphitheaters*.

At Athens are still seen the remains of the temple of Bacchus, which was the first theater in the world, and was a master-piece in architecture. All theaters were consecrated to Venus and Bacchus.

THEATER, among the *Moderns*, more peculiarly denotes the stage, or place on which the drama, or play, is exhibited; answering to the proscenium of the ancients.

In its full latitude, however, the theater includes the whole play-house: in which sense it is a spacious room, or hall, part of which is taken up by the *scena*, which comprehends the stage, the decorations, and the machines; and the rest is distributed into a space, called the *pit*, or *parterre*, which is covered with seats, boxes, &c. and terminated with an elevation of one or two galleries, disposed into benches ascending over one another. See *DRAMATIC Scenery*, *PLAY-HOUSE*, and *SCENOGRAPHY*.

THEATER is also used in *Architecture*, chiefly among the Italians, for an assemblage of several buildings, which, by a happy disposition and elevation, represents an agreeable scene to the eye.

Such are most of the vineyards at Rome; but particularly that of Monte Dragone, at Fiescati; and in France, the new castle of St. Germain en Laye.

THEATER, *Anatomical*, in a school of *Medicine* and *Surgery*, is a hall, with several rows of seats, disposed in the circumference of an amphitheater, having a table, bearing on a pivot, in the middle, for the dissection of bodies.

Such is the anatomical theater of the royal garden at Paris.

The *Theater* at Oxford is a beautiful building, erected by archbishop Sheldon, for the use of scholastic exercises. See *OXFORD*.

THEATINES, an order of nuns, under the direction of the Theatines.

There are two kinds of Theatines, under the title of
VOL. XXXV.

"Sisters of the Immaculate Conception," who form two different congregations, the one engaged by solemn vows, and the other only by simple vows. Their common foundress was Ursula Benincasa. Those who make the simple vows are the most ancient, and are called absolutely "Theatines of the Congregation:" they had their rise at Naples in 1583.

The others are called "Theatines of the Hermitage:" the whole business of these is praying in retirement, and an austere solitude, to which they engage themselves by solemn vows.

The Theatines of the first congregation take care of the temporal concerns of these last. Their houses stand together, and communicate by a large hall. Their foundress drew up their constitutions, and laid the foundation of their house at Naples; but died before it was finished.

Gregory XV. who confirmed the new institute under the rule of St. Augustine, appointed that they should be under the direction of the Theatines. Urban VIII. revoked this article by a brief in 1624, and subjected them to the nuncio of Naples: but Clement IX. annulled this brief, and submitted them anew to the Theatines by a brief in 1668.

THEATINS; a religious order of regular priests: thus called from their first superior Don John Pietro Caraffa, archbishop of Chieti, in the kingdom of Naples, which was anciently called *Theate*.

The same archbishop became afterwards pope, by the name of Paul IV. after having been a companion of Gaetan, or Cajetan, a Venetian gentleman, the first founder of this order, at Rome, in 1524.

The Theatins were the first who assumed the title of *regular clerks*. They have not only no lands, or fixed revenues, either in common, or in propriety; but they do not even ask or beg any thing; but wait for what Providence shall send them for their subsistence.

They employ themselves much in foreign missions; and in 1627, they entered upon Mingrelia, where they have an establishment: they have had the like in Tartary, Circassia, and Georgia; but this they have since abandoned.

Their first congregation appeared at Rome in 1524, and was confirmed in the same year by Clement VII. Their constitutions were drawn up at a general chapter in 1604, and approved by Clement VIII. They wear the priest's habit.

THEATRE. See THEATER and AMPHITHEATER.

THEATRIC BANDAGES, a term used by Hippocrates, to express the parade of surgery in applying bandages for show, when there was no real use in them. All such bandages he called *theatric*, only proper to be looked at.

THEAUA, in *Ancient Geography*, a town of Spain, in the interior of the Tarragonensis.

THEAVE, a term applied in some districts to an ewe of the first year. It is sometimes written *thave*, and also *thief* in different districts.

THEBÆ, or THEBES, in *Ancient Geography*, a considerable, and in some respects the principal, town of Bœotia, situated towards the middle of the country, near the river Ismené, S.E. of the lake Copais. This town owed its origin to Cadmus; but being considerably augmented, the part of the town which was seated upon an eminence, and which was called Cadmæa from the name of its founder, was regarded as a citadel in reference to the lower town. Here was a spring, which conveyed water to the city by subterraneous channels. Amphion and Zethus, having taken possession of the country, joined the upper and lower towns, and called the place Thebes. According to Homer it had seven gates, the intervals being occupied by walls. It is

said to have been 43 stadia (1 league 1563 toises) in circumference. Its environs are embellished by two rivers, by meadows and gardens. Myron of Byzantium says, that Amphion was the first person who erected an altar to Mercury, and that the god recompensed his zeal by giving him a lyre. The Thebans carried on various wars with the Plataeans for ascertaining their respective limits; and against the Athenians at Plataea for having sought the friendship of the king of Persia against the common interest of the Greeks. In process of time, the Thebans avenged themselves by defeating the Athenians at Delium, near the Tanagra. The Macedonians, after the battle of Cheronæa, placed a garrison at Thebes, where it remained till after the death of Philip. Alexander having taken the city, and expelled its inhabitants, who retired to Athens, Cassander, the son of Antipater, re-established them there, with the assistance of the Athenians, the Messenians, and the Megalopolitans. Sylla at length reduced them to extreme misery, for having declared in favour of Mithridates.

In the time of Pausanias, the whole lower part of the town was in ruins, except the temples, and the citadel only was inhabited and denominated Thebes. The temple of Apollo was seated on an eminence near one of the gates, and the river Ismené, which passed by it, gave to the god and the hill on which his temple stood the name of Ismenius. Mercury and Minerva had each a statue of marble at the entrance of the vestibule of this temple: that of Mercury was the work of Phidias, and that of Minerva was executed by Scopas. The statue of Apollo in the temple was wrought of cedar-wood. In this temple were also brazen tripods of excellent workmanship. Hercules Promachus had a temple near another of the gates of the city, in which was his statue of marble; a colossal figure by Alcamenes, and his labours by Praxiteles. The temple of Ammon had a statue executed by Calamis and dedicated by Pindar. Here was also the temple of Fortune, and the goddesses held Plutus in her arms under the form of an infant. The temple of Ceres Thesmophorus, or the legislator, had been anciently the house of Cadmus, in which was exhibited a bust of the statue of the goddesses. The theatre was near another gate, and near it a temple of Bacchus Lylius. The temple of Diana Euclea was in the same quarter; the statue of the goddesses was the work of Scopas. Jupiter, surnamed the *Highest*, had a temple near the gate of this appellation. Here were a place of exercise and a stadium; and in the midst of the stadium was the tomb of Pindar. The river Iree passed near Thebes, and beyond it were the ruins of the house of Pindar, and a kind of chapel which this poet had built in honour of Cybele. Her statue was formed of Pentelic marble. Entrance into the chapel was allowed only one day in the year. The temple of Themis was near one of the gates of Thebes, and her statue was of white marble. Jupiter Agoreus and the Parææ had also their temples. The statue of Hercules Rhinocolutes was in full view in this part of the city. The sacred wood of Ceres Cabiria and of Proserpine lay at about 25 stadia from Thebes. The temple of the Cabiri was at the distance of seven stadia. According to Pausanias, there was seen at Thebes a statue of Venus Urania, which was said to have been formed of parts of the ships that brought Cadmus into Greece. It was the most ancient statue in Greece. The population of this city was very considerable. When it was taken by Alexander, more than 6000 persons perished, and more than 30,000 were sold for slaves. Some priests were spared and many citizens fled. Hence we may presume, that the number of inhabitants in Thebes and its district might amount to 50,000 of all ages and sexes, without in-

cluding slaves. The inhabitants, like those of Athens, were divided into three classes; the first composed of citizens, the second of naturalized foreigners, and the third of slaves. The Thebans were deemed to be courageous, insolent, and vain; and murders were frequently the consequence of the most frivolous quarrels. The women were both well made and generally of a fair complexion, of a noble carriage, and not inelegant dress; their voice was remarkably sweet and tender; and that of the men harsh and disagreeable, and in some measure suited to their character. The "sacred battalion" of Thebes is famous in history. It consisted of a body of young warriors, brought up together, and maintained at the public expence, in the citadel. Their exercises, and even their amusements, were regulated by the melodious sounds of the flute; and in order to prevent their courage from degenerating into blind fury, care was taken to inspire them with the noblest and most animated sentiments. Each warrior chose from the band a friend, to whom he remained inseparably united. These 300 warriors were anciently distributed in troops at the head of the different divisions of the army Pelopidas, who had frequently the honour of commanding them, having made them fight in a body, the Thebans were indebted to them for almost all the advantages they gained over the Lacedæmonians. Philip destroyed this hitherto invincible cohort at Cheronæa; and the prince, seeing those young Thebans stretched on the field of battle, covered with honourable wounds, and lying side by side on the ground on which they had been stationed; could not restrain his tears, but bore a noble testimony to their virtue as well as their valour. Travels of Anacharsis, vol. iii. See THIVA.

THEBÆ, a town of Upper Egypt, on the right bank of the Nile. According to the ideas given us of this town by Homer, it was the most celebrated of antiquity. Ancient authors have given very different accounts of its extent. In the time of Strabo, this city had been destroyed. It had been ravaged by Cambyfes; it was afterwards despoiled of its riches by Ptolemy Philometer; and under the reign of Augustus, it was severely treated by Gallus on account of its rebellion. From this time it fell into a state of decline, from which it has not recovered. Tacitus mentions it as a town in ruins; and Juvenal speaks thus of it: This city extended on both sides of the Nile, although it was more particularly situated on the right bank of this river: a considerable portion of it lay to the left, which, according to Strabo, bore the name of "Memmonium." For a further account of this city, see THEBES.

THEBÆ was a name given to many ancient towns. *Thebe* was a town of Asia, in Cilicia hypoplaciana, situated on a plain, at the foot of mount Placion.—Also, a town of Judea, in the half-tribe of Manasseh, on this side of Jordan.—Also, a town of Macedonia, in the Phthiotide, 100 stadia from the town of Alos, according to Strabo.—Also, a town of Asia Minor, in Ionia, in the vicinity of Miletus.—Also, a town of Greece, in Attica.—Also, a town of Asia, in Cataonia.—Also, a town of Asia, in Syria.—Also, a town of Palestine, in the tribe of Ephraim.—Also, a town of Arabia Felix, upon the coast of the Red sea, in the country of the Cinædocolpites. Ptolemy.

THEBAID, THEBAIS, a famous heroic poem of Statius, the subject of which is the civil war of Thebes between the two brothers Eteocles and Polynices; or Thebes taken by Thebes.

Statius was twelve years in composing his Thebaid, which consists of twelve books: he wrote under Domitian. He is censured by the best critics, as Bossu, &c. for a vicious multiplicity of fables and actions, for too much heat and

extravagance, and for going beyond the bounds of probability.

Several Greek poets had composed Thebais, or poems of this name, before him; the principal were Antagoras, Antiphanes of Colophon, Menelaus the Ægean; and an anonymous author mentioned by Pausanias, lib. ix.

Aristotle, praising Homer for the simplicity of his fable, opposes to him the ignorance of certain poets, who imagined that the unity of fable or action was abundantly provided for by the unity of the hero, and who composed Theiseids, Herculeids, &c. in each of which, they collected every thing that had ever happened to their principal person.

THEBAIS, or THEBAID, called also *Said*, in *Ancient Geography*, a name given to Upper Egypt, from its principal city Thebes. It is in scripture called Pathros. This is the most southern part of Egypt next to Æthiopia, and is almost as extensive as all the other parts of Egypt, including the country on both sides of the Nile down to the Heptanomis or Middle Egypt; its best city, according to the ancients, being Lycopolis, (see SIUT,) on the western, and Antæopolis on the eastern side of the river. These dimensions agree pretty exactly with the present extent of Al Said, the most northern city of which is Manfelût. In this part of Egypt there were formerly several cities of great note; such as Lycopolis, on the scite of which is supposed to be the present Manfelût; Hypsele, or Aboutig, about a mile W. of the Nile; Aphroditopolis; Ptolemais; Abydos, once the second city of the Thebaid, famous for the magnificent palace of Memnon, but in the time of Strabo only a village; Little Diopolis, probably the present *Hou* (which see); Tentyra, the inhabitants of which were famous for their enmity to the crocodile, the ruins of which are still to be seen at *Dendera* (which see); Latopolis, or *Efnah* (which see); Great Apollinopolis, on the scite of which Etfu is now supposed to stand (see APOLLINIS URBS, and ETFU); and Elephantine, on an island of that name, where are the ruins of a small temple. On the east side of the Nile are Antæopolis, on the scite of which Siout is supposed to have been built; Paffalus, conjectured to be the present Gava-Kiebre, where is seen a very beautiful portico of a temple, with eighteen pillars, in three rows; Panopolis and Cheramis, supposed to be the same city, but distinguished by Herodotus; the scite of Panopolis is said to be that of the present Akraim, about a mile from the river; Chenoboscia; Cæne or Neapolis, perhaps the present Kene, a small town on an eminence, about a mile from the river Coptos or Kept, and called by Pliny the emporium of commodities brought from India and Arabia; Coptos, where Christians were formerly very numerous (see COPTOS); Apollinopolis (see APOLLINIS URBS, or *Apollinopolis Parva* or *Kous*); and *Thebes*; which see. To the south of Thebes, and on the same side of the river, were the following cities: *viz.* Chnumis or Cnuphis; Elethya or city of Lucina; Onebos, now Comombo, or the hill of Ombo, on which are seen the ruins of an ancient temple (see COMOMBO); Syene; Philæ, (see PHILOE,) an island deemed sacred from an opinion that Osiris was buried there. The Thebaid in the first ages of the church was rendered famous by the number of hermits who resorted thither.

THEBAIS, a river of Asia Minor, in Caria. Pliny says that it traversed the town of Trallis.

THEBAN HARP. See HARP.

THEBANUS OPHITES, in *Natural History*, a name given by some of the ancients to that species of the ophites, or serpentine marble, more commonly called *ophites niger*, the black serpentine.

THEBARMAI, in *Ancient Geography*, Ormed, a town

of Asia, S.W. of lake Spauta, and at some distance from it, lies between a mountain and a small river that falls into this lake. The worship of fire prevailed in this province, under a persuasion that the first pyreum was kindled by Zoroaster himself.

THEBES, the capital city of the Thebais, or Upper Egypt, which was deservedly reckoned one of the finest cities in the world. It was also called Diopolis, or the city of Jupiter, and was built, as some say, by Osiris, but according to others, by Busiris. Its length, in the time of Strabo, was eighty furlongs, or ten miles; but this was very inconsiderable, compared with its ancient extent, before it was ruined by Cambyfes, which, we are told, was no less than 420 stadia, or 52½ miles. Its wealth was so great, that, after it had been plundered by the Persians, what was found, on burning the remains of the pillage, amounted to above 300 talents of gold, and 2300 of silver. The 100 gates of Thebes are mentioned by Homer, and, after him, by many others; but some think that this was not the number of the gates, but of the temples; and that from them the city had the epithet Hecatompylos, expressing a definite for an indefinite number. Pomponius Mela, and others, by the 100 gates, understand so many palaces of princes, each of whom could, on any occasion, arm and send out 20,000 fighting men, and 200 chariots. A modern traveller could observe no signs or remains of walls round Thebes: and if it had none, we must conclude, that by 100 gates, were meant the gates of the temples, or rather the palaces of great men. In Strabo's time the city stood chiefly on the east side of the river. At Thebes there were anciently four remarkable temples; one of them is said, by Diodorus Siculus, to have been 1½ mile in circumference, and 45 cubits in height, with walls 24 feet thick.

The venerable ruins of this city, probably the most ancient in the world, says Mr. Browne (*Travels*, &c.), extend for about three leagues in length along the Nile. East and west they reach to the mountains, a breadth of about 2½ leagues. The river here is about 300 yards broad; the circumference of the ancient city must therefore have been about 27 miles. In sailing up the Nile, the first village that occurs within the precincts is Kourna, on the W., with few houses, as the people chiefly live in the caverns. Next is Abuhedjodj, a village, and Karnac, a small district, both on the E. The largest portion of the city stood on the eastern side of the river. On the S.W. Medinet-Abu marks the extremity of the ruins; for Arment, which is about two leagues to the S., cannot be considered as a part. Modern authors have styled the scite of Thebes, "*Luxor*" (which see); and others have denominated it "*Akfor*;" both which terms are, in Mr. Browne's opinion, corruptions of "*El Kasfur*," the appellation still applied to the ruins by the Arabs. The most considerable ruins are those on the E. of the Nile. The chief of these is the "*great temple*," an oblong square building of vast extent, with a double colonnade, one at each extremity. The massy columns and walls are covered with hieroglyphics. The "*great temple*" stands in the district called Karnac. Next to this in importance is the temple at Abu-Hedjadj, and here are numerous ruins, avenues marked with sphinxes, &c. On the W. side of the Nile appear two colossal figures, apparently of a man and woman, formed of a calcareous stone like the rest of the ruins:—remains of a large temple, with caverns excavated in the rock:—the magnificent edifice styled the "*palace of Memnon*," some of the columns being about 40 feet high, and about 9½ in diameter: the columns and walls are covered with hieroglyphics: this stands at Kourna: Behind the palace is the passage denominated

“Bibân-el-Molûk,” leading up the mountain; at the extremity of which passage, in the sides of the rock, are the celebrated caverns known as the sepulchres of the ancient kings. These sepulchres, which have lately been discovered, are particularly described by Mr. Browne. In the cells or recesses of the passage of the largest of these, appear the chief paintings, representing the mysteries, which, as well as the hieroglyphics covering all the walls, are very fresh. Our traveller particularly observed the two harpers described by Bruce, but his engraved figures, he suggests, seem to be from memory. Although Pococke and many others are of opinion that Thebes was never surrounded by a wall, Mr. Browne inclines to a contrary opinion, from some faint remains which are still visible.

We are principally indebted to Denon (*Travels in Upper and Lower Egypt*, in 3 vols. 8vo. translated by Aikin), for an interesting account of the magnificent ruins of Thebes, as well as of other places in Egypt, illustrated by beautiful engravings. Four large hamlets (says Denon) divide amongst them the remains of the ancient monuments of Thebes, whilst the river, by the sinuosity of its course, seems still proud of flowing among its ruins. In crossing the ground occupied by the ancient Thebes, Denon found nothing but temples; not a vestige of the 100 gates so celebrated in history; no walls, quays, bridges, baths, or theatres; not a single edifice of public utility or convenience. Temples indeed were numerous, and walls covered with obscure emblems and hieroglyphics, which attested the ascendancy of the priesthood, who still seemed to reign over these mighty ruins. The space occupied by this incomprehensible town now enfolds four villages and as many hamlets, thinly scattered over immense fields. Passing through the territory of Thebes on another occasion, Denon saw at the distance of three-fourths of a league from the Nile, the ruins of a large temple not before noticed by any traveller, which may give an idea of the immensity of that city, since, if we suppose that it was the last edifice on the eastern side, it is more than $2\frac{1}{2}$ leagues distant from Medinet-Abu, where the most western temple is situated. The temple, on the site of which the village of Karnac has been built, is of such a circumference, that it would require half an hour to walk round it. Herodotus has given us a more correct idea of its grandeur and magnificence. Diodorus and Strabo, who examined it in its ruinous state, appear to have furnished a description of its present condition, but none of the travellers who have copied the accounts of these writers have presumed (says Denon) to prefer to this temple that of Apollinopolis at Etfu, that of Tentyra, and the simple portico at Esneh. It is probable (says this writer) that the temples of Karnac and Luxor were built in the time of Sesostris, when the flourishing condition of the Egyptians gave birth to the arts among them, and when these arts were displayed to the world for the first time. Of the 100 columns of the portico of the temple of Karnac or *Carnac* (which see), the smallest are $7\frac{1}{2}$ feet in diameter, and the largest 12. The space occupied by its circumvallation contains lakes and mountains. This edifice is now in a degraded state. The sphinxes have been wantonly mutilated; and the avenue that leads from Karnac to Luxor, nearly half a league in extent, contains a succession of chimerical figures to the right and left, with fragments of stone walls, of small columns, and of statues.

Luxor (which see), the finest village in these environs, is also built on the site of the ruins of a temple, not so large as that of Karnac, but in a better state of preservation, the masses not having as yet fallen through time, and by the pressure of their own weight. The most colossal parts con-

sist of fourteen columns of nearly eleven feet in diameter, and of two statues in granite, at the outer gate, buried up to the middle of the arms, and having in front of them the two largest and best preserved obelisks known.

A peculiarity belonging to the temple of Luxor, is, that a quay, provided with an epaulement, secured the eastern part, which was near the river, from the damages the inundations might otherwise have occasioned. The epaulement, which since its original structure has been repaired and augmented in brick-work, proves that the river has not changed its bed; and its preservation is an evidence that the Nile has never been banked by other quays, since no traces of similar constructions are elsewhere to be met with.

Nothing can be more grand, and at the same time more simple, than the small number of objects of which this entrance is composed. No city whatever makes so proud a display at its approach as this wretched village, the population of which consists of two or three thousand souls, who have taken up their abodes on the roofs and beneath the galleries of this temple, which has, nevertheless, the air of being in a manner uninhabited.

Denon has particularly described the tombs above-mentioned, in the village of Kurnu, the ancient Necropolis of Thebes; and he concludes with remarking, that the mystery and magnificence observable within these excavations, and the number of slaves by which they are protected, indicate, that the religious worship which had scooped out and decorated these grottoes, was the same as that which had raised the pyramids; but our limits forbid a farther detail.

THEBET, in *Chronology*. See *TEBET*.

THEBIT BEN CORAH, or THAËT EBN KORRA, in *Biography*, an Arabian teacher of philosophy and mathematics, was a native of Harran, and belonged to the sect of the Sabæans, and on this account was surnamed “Al-Sabi-Al-Harrani.” The time in which he flourished is uncertain. Some say that he was born in the 221st year of the Hegira, or A.D. 835; others refer him to the 10th century; and others again have placed him in the 12th or 13th century. He was secretary to the caliph Mothaded; and was distinguished by his skill in the mathematics, and by his knowledge of astronomy. He is said to have observed the declination of the ecliptic, which he fixed at $23^{\circ} 33' 30''$: and from this circumstance it has been concluded, that he lived in the 12th or 13th century, or that he was contemporary with Almeon and Prosalus, who about that period assigned to the ecliptic the same declination. To Thebit has been ascribed the origin of the astronomical sect, which maintained the trepidation of the fixed stars. It was his opinion, founded on some erroneous observations, that the fixed stars moved for some time according to the order of the signs; that they afterwards proceeded in a retrograde direction and returned to their former places, after which they assumed a direct motion; and that then they had an irregular motion, which was rapid for a certain period, then became slower, and at last insensible. According to Thebit, the obliquity of the ecliptic was variable, and subject to similar periods of increase and decrease. His opinions prevailed for a considerable time, not only among the astronomers of his own nation, but among some Christians. Montucla *Hist. de Math.* Pococke, p. 377. Fabr. *Bib. Græc.* v. ii. p. 354.

THECA; SHEATH, in *Anatomy*, hollow organs, serving to contain others. The thecæ of the fingers are strong sheaths binding down the flexor tendons. The theca vertebralis is the sheath of the dura mater lining the vertebral canal, and containing the medulla spinalis.

THECA,

THECA, in *Botany*, the Latin word for a *cell*, *sheath*, or *case*, is used occasionally by some botanists in their descriptions of seed-vessels; and especially by Acharius, for those minute vertical parallel cells, in the disk of the shields or tubercles of a *Lichen*, in which its seeds are lodged. See **LICHENES** and **PEZIZA**.

THECHES, in *Ancient Geography*, a mountain of Asia, in Armenia, according to Xenophon, who says that the Greeks, after leaving Gymnia, arrived on the fifth day at the sacred mountain called Theches, and from thence they for the first time perceived the Euxine sea, which occasioned loud exclamations of joy.

THECUA, a town of Palestine, in the tribe of Juda; situated 12 miles S. of Jerusalem, according to Eusebius and Jerome. Josephus says that it was in the vicinity of Herodium. See **TEKOÄ**.

THEDINGHAUSEN, in *Geography*, a town of Germany, in the county of Hoya; 12 miles N.N.W. of Hoya.

THEDO, in *Ichthyology*, a name given by Figulus and others to the trout.

THEFT, **FURTUM**, in *Law*, an unlawful, felonious taking away another man's moveable and personal goods, against the owner's will, with an intent to steal them. See **LARCENY**.

Open theft from the person, or in the presence of the owner, is properly called *robbery*; which see.

THEFTBOTE, the receiving of a man's goods again from a thief, or other amends, by way of composition, and to prevent prosecution, that the felon may escape unpunished; the punishment of which is now fine and imprisonment.

This is frequently called *compounding of felony*. By 25 Geo. II. c. 36. even to advertise a reward for the return of things stolen, with no questions asked, or words to the same import, subjects the advertiser and the printer to a forfeiture of 5*l.* each.

THEIFENECE, in *Geography*, a town of Carinthia; 3 miles N.E. of Wolfsberg.

THEIMSDORF, a town of Lusatia; 6 miles E. of Rothenburg.

THEINRED, in *Biography*, preceptor of the monastery of Dover, and author of a treatise on music, in Latin, preserved among the MSS. of the Bodleian Library, in three books, written about the year 1371.

The first book treats of musical proportion; "De Proportionibus Musicorum Sonorum." This is a very early treatise upon harmonics, in which, when he speaks of the major and minor semitone, and of the different portions into which they are divisible, his doctrine is illustrated by many numerical tables, and nice splittings of tones into commas; "De Comatis; alia Proportio ejusdem Comatis, &c." which prove a *temperament* of the scale to have been then in use.

The second book treats of musical concords; "De Consonantiis Musicorum Sonorum." Here, after specifying the different kinds of concords, he informs his reader, that in *organising*, major and minor thirds, as well as sixths, are admissible in succession.

The third book contains diagrams and scales innumerable of different species of octave, in a literal notation. No musical characters, or examples of practical music in common notes, appear throughout the treatise.

The praises bestowed by Pits, Bale, Tanner, and others on Theinred, whose name is sometimes written Thaurad, and Thinred, make it necessary to acquaint such of our readers as may be inclined to take the trouble of examining this

tract themselves, that, like many other musical writings of the middle and lower ages, it but ill rewards the drudgery of an entire and careful perusal; for after perseverance has vanquished the abbreviations, and the barbarism and obscurity of the Latin, the vain speculations and useless divisions of the scale, with which this work so much abounds, and which could have been but of small utility to practical music, at the time when it was written, are such, that now, since the theory of sound is so much better understood and explained by the writings of Galileo, Merfennus, Holder, Smith, and many others; our old countryman, Theinred, may henceforth remain peaceably on his shelf, without much loss to the art or science of music. Bodl. 842. 1. De legitimis ordinibus Pentachordorum et Tetrachordorum, Pr. Quoniam Mulicorum de his Cantibus frequens est distinctio, &c. 46 folios, small size. Walther in his Lexicon calls this work a Phoenix.

THEIOCRUS, in the *Materia Medica of the Ancients*, a name given by some to the melanteria.

The name *theiocrus* signifies only sulphur-coloured, and was at first used with the name of vitriol, as expressive of the difference of this kind from others; but in time it became common to use it alone.

THEISM. See **DEISM**.

THEISOA, or **THISOA**, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia.

THEIUM, a town of Greece, in Athamenia.

THEIUS, a river of the Peloponnesus, in Arcadia, which discharged itself into the Alphæus.

THEKA, in *Botany*, the Malabar name of the Teak tree, retained as generic by Jussieu. See **TECTONA**.

THEKUPHÆ. See **TEKUPHÆ**.

THELA, in *Botany, so named by Loureiro, Cochinch. 119, from *θηλα*, a *nipple*, in allusion to the little glandular prominences which cover the calyx, appears, by his description, to be the same genus with the Linnæan **PLUMBAGO**. See that article.*

THELARY, in *Geography*, a town of Hindoostan, in Bahar; 18 miles S.W. of Bahar.

THELBALANA, in *Ancient Geography*, a town of Asia, in the Greater Armenia. Ptol.

THELBENCANA, a town of Asia, in Babylonia, on an arm of the Euphrates.

THELDA, a town of Asia, in Mesopotamia, on the banks of the Euphrates. Ptol.

THELE, a word used by some to express the nipple, and by others for the whole breast.

THELEBOÆ, in *Ancient Geography*, a people of Epirus, in Acarnania, who passed into Italy, and established themselves in the island of Caprea.

THELEBOLUS, in *Botany, from *θηλα*, a *nipple*, and *βολος*, a *cast*, or *throw*, because the little vesicle, lodging the seeds, resembles a nipple, and is thrown off with a degree of elasticity. The name was originally written *Thelebolus*, but the above is justly preferred.—Tode Mecklenb. v. 1. 41. Pers. Syn. 116.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi angiocarpi*.*

Ess. Ch. Receptacle cup-like, somewhat globose, entire at the edge, discharging a papillary, nearly naked, seed-vessel.

1. Th. *stercoreus*. Small Nipple-fungus. Pers. n. 1. Tode n. 1. t. 7. f. 56.—Found by Tode on the dung of swine, after rainy weather in June and July. He compares it to the roe of fish in appearance, and to poppy-seed nearly in size. The colour is a tawny yellow. Each individual is globular, attached at the bottom by capillary roots, and crowned with a small papillary tubercle, of a more

more orange or golden hue than the rest. This is at length thrown off, with a sudden and strong elastic force, leaving a minute, bordered, viscid pit, or cup, which gradually dilates into a level surface.

The minute fungus above described is closely related to *Sphaerobolus*, and still more nearly perhaps to *Pilobolus*. (See those articles.) Whether it might be allowable to comprehend them under one genus, may admit of much dispute. Even the many-cleft *receptacle*, or *involucrum* of *Sphaerobolus* can hardly be deemed a sufficient important difference to supersede this measure, and still less the elongated figure, or pellucid substance, of *Pilobolus*. Botanists who bestow their concentrated attention exclusively on particular tribes of plants, are prone to multiply distinctions; but they are not rashly to be corrected by those who have not looked so closely, nor, perhaps, so well.

THELEDA, in *Ancient Geography*, a town of Asia, in Syria, situated on a plain W. of Seriana, and E. of Capparæ.

THELEPHORA, in *Botany*, from *θηλα*, a nipple, and *φορος*, to bear, because of the generally papillary covering of the under surface.—Willd. Berol. 396. Perf. Syn. 565. Schrad. Spicil. 182. (Craterella; Perf. Obs. Mycol. v. 1. 39. Corticium; ib. 37.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi gymnocarpi*.

Ess. Ch. Head coriaceous, dilated; minutely papillary, bristly, or smooth, beneath. An ample, and, in our opinion, rather vague genus of the fungus tribe, of which Perfoon reckons up forty-seven species, ranged under three sections, once considered by him as distinct genera. We shall, after our usual manner, select a few examples of each.

SECT. 1. CRATERELLA. Head undivided, hollow or funnel-shaped above, with a shaggy disk. Two species.

Th. *pallida*. Pale Thelephora. Perf. n. 1. "Ic. et Deser. Fung. 3. t. 1. f. 3, sub *Craterella*."—"Aggregate, corky, pale. Head concave, shaggy with scales."—Rarely found on the ground in moist woods. The stalk is very short; villous at the base. Head rough beneath, with little bristles, visible under a magnifying glass. Perfoon.

Th. *caryophyllea*. Carnation Thelephora. Perf. n. 2. Albert. and Schwein. Nisk. 272. (Craterella *ambigua*; Perf. Obs. Mycol. v. 1. 39. t. 6. f. 8—10. *Helvella caryophyllea*; Schæff. Fung. v. 4. 115. t. 325. Dickf. Crypt. fasc. 1. 20. *Auricularia caryophyllea*; Bulliard. t. 278. 483. Sowerb. Fung. t. 213.)—Head funnel-shaped, thin, purplish-brown, fringed, variously jagged or crisped.—Found on the ground in fir woods. Mr. Woodward first met with this species in Britain, near Bungay, Suffolk. Continental botanists usually speak of it as rare, but Mr. Sowerby says it is "a very common parasite on the exposed fantastic roots of old firs, in autumn." The substance is tough and somewhat woody; the colour a chocolate-brown. The plants often grow in masses, attached by their upper side to flicks, old bark, &c., and are from one to three inches in diameter. Sometimes the shaggy edge is white. Perfoon in his Obs. Mycol. above quoted seems disposed to think the present fungus may vary so much as to become *Ramaria palmata* of Holmkiöld, Fung. Dan. v. 1. 106. t. 33; but surely the multiplied divisions and ramifications of the latter, as well as its smoothness and colour, preclude such an idea.

SECT. 2. STEREUM. Head halved, finally horizontal. Thirteen species.

Th. *terrestris*. Ground Thelephora. Perf. n. 3. Ehrh. Crypt. n. 179. (Th. *mesenteriformis*; Willd. Berol. 397,

t. 7. f. 15.)—Somewhat imbricated, dull brown. Head flattened, shaggy with fibres. On sandy ground. This seems to us a mere variety of the last, or rather its most usual form, as represented in Mr. Sowerby's t. 213. Yet Perfoon cites this plate, with doubt, under his fourth species, *Th. laciniata*. He seems to lay too much stress on the absence or presence of a stalk, and perhaps makes too many distinctions.

Th. *rubiginosa*. Rusty Thelephora. Perf. n. 6. (Th. *fragilis*; Ehrh. Crypt. n. 238. *Helvella rubiginosa*; Dickf. Crypt. fasc. 1. 20. *Auricularia ferruginea*; Bulliard. t. 378. Sowerb. Fung. t. 26.)—Imbricated, rigid, rusty-brown, smooth on both sides, with scattered, rather large, knobs.—Not uncommon on gate-posts or pales, generally placed so low as to be partly hid by the earth and neighbouring plants, as Mr. Sowerby remarks. It is very distinct from the foregoing, soft like velvet to the touch; the under side bearing scattered, roundish prominences, which, however, do not appear concerned in the fructification. The edge is usually pale. No part is hairy or shaggy. The diameter of each plant is about an inch.

Th. *ferruginea*. Snuff-coloured Thelephora. Perf. n. 9. Albert. and Schwein. Nisk. 273. (*Auricularia tabacina*; Sowerb. Fung. t. 25.)—Wavy, somewhat reflexed, bright brown. Head thin, nearly even, slightly downy; hairy underneath.—Frequent on stumps and rotten branches, in various situations. The plants are sessile, attached by the back, projecting over each other, of an elegant undulated figure; the colour of both sides a bright reddish-brown, especially the upper, elegantly contrasted with the light-yellow border.

Th. *hirsuta*. Common Hairy Thelephora. Perf. n. 11. Willd. Berol. 397. Albert. and Schwein. Nisk. 274. (Th. *pallida*; Ehrh. Crypt. n. 169. *Auricularia reflexa*; Bulliard. t. 274. Sowerb. Fung. t. 27.)—Aggregate, rounded, coriaceous, convex, somewhat zoned, yellowish; shaggy above; smooth and tawny beneath.—Frequent on rotten stumps, posts, pales, tubs, &c.; either growing solitary, and roundish, about an inch in diameter; or in continued, confluent, somewhat imbricated masses. The under side is yellow or tawny; the upper of a pale yellowish-brown, marked with different concentric shades, and rough with imbricated soft shaggy hairs. The whole is often tinged with black, as if smoked. It varies in size as well as colour, and often consists of an expanded orange-coloured surface, closely pressed by its back to the wood, previous to its acquiring any projection by which the upper side is exposed. In this state it might be referred to the next section. *Auricularia papyrina*, Bulliard t. 402, seems nearly akin to this.

SECT. 3. CORTICIUM. Plant laid entirely on its back, indeterminate in form, papillary, various in substance.—Thirty-two species, divided into subordinate sections, according to the colour, whether pale or dark red, yellowish, brown, grey, or white.—It is very necessary to trace the progress of the species of this division, in order to be certain they do not, at any period, acquire a distinct upper surface, so as to range under the preceding.

Th. *quercina*. Oak Thelephora. Perf. n. 16. Albert. and Schwein. Nisk. 276. (Th. *carnea*; Ehrh. Crypt. n. 269. (*Auricularia corticalis*; Bulliard t. 436. f. 1.)—Oblong, coriaceous, rugose, pale flesh-coloured; the margin somewhat involute, of a blackish-brown at the back.—Found running longitudinally along decayed branches of oak. Each plant is two or three inches in length, somewhat oval, of a light flesh-coloured hue, with a powdery or downy surface, which water will not moisten, and which is besprinkled with round depressed protuberances, obscurely

representing the shields of a *Lichen*. The margin soon becomes elevated and inflexed, especially by drought or cold, and displays the blackish under side, which ought to be the upper.

Th. cruenta. Blood-red *Thelephora*. Perf. n. 24.—“Smooth, coriaceous, tuberculated, blood-red.”—An elegant species, found on the branches of trees, and communicated by Ludwig from Misnia. *Perfoon*.

Th. sanguinea. Gory *Thelephora*. Perf. n. 25. (*Tremella cruenta*; Engl. Bot. t. 1800.)—“Widely spreading on the ground, somewhat gelatinous, blood-coloured, smooth.”—“This singular species,” says *Perfoon*, “grows in the streets of towns, about the walls of houses, looking at a distance like blood poured on the ground. By drying it becomes paler. Is it not rather to be referred to the order of *Alga*?” In this last suggestion we readily concur. The whole is truly an expanded mass of minute, uniform, gelatinous, pellucid granulations, with nothing of a coriaceous or fungous texture, nor any other character of the present genus.

Th. hydnoides. Awl-bearing *Thelephora*. Perf. n. 28. Albert. and Schwein. Nisk. 279. (*Corticium hydnoides*; Perf. Obs. Mycol. v. 1. 15.)—Spreading, concealed, orange-yellow, bearing awl-shaped elongated prominences.—This spreads under the separated cuticle of decayed dry branches of beech, which it sometimes totally encircles, extending to the length of four or six inches. Its great peculiarity consists in the awl-shaped projections, thrown out from its surface, to the height of two or three lines, which either penetrate, or force off, the superjacent cuticle of the tree, and, except in their great irregularity of size and figure, resemble the prickles of a *Hydnum*.

Th. umbrina. Umber-brown *Thelephora*. Perf. n. 36. Albert. and Schwein. Nisk. 281.—Spreading on the ground, soft, of an umber brown; the margin whitish and rather downy.—Found on the ground, in a sandy soil, spreading to the extent of two or three inches, and not of a very thin substance. *Perfoon* speaks of it as very rare, but the observing authors of the *Fungi Niskienfes* find it not unfrequently, in August and the following months, in shady sandy places.

Th. casia. Grey Ground *Thelephora*. Perf. n. 40. (*Corticium casium*; Obs. Mycol. v. 1. 15. t. 3. f. 6.)—Orbicular, on the ground, nearly smooth, of a greyish ash-colour.—Not unfrequent in autumn, on the bare ground, from one and a half to three inches broad, with a white, fibrous, rounded, scalloped edge. The grey surface is besprinkled with minute powdery seeds, regularly disposed in spots, four together. *Perfoon*.

Th. lactea. Milk-white Fir *Thelephora*. Perf. n. 45.—“Nearly orbicular, of a livid white; somewhat fleshy in the middle; fibrous at the margin.”—Rarely found on the bark of the Spruce Fir. The surface is smooth. The colour becomes paler by drying. *Perfoon*.

Albertini and Schweiniz describe several more species of this genus, to which every thing of a membranous texture, and fungous aspect, seems to be referred by authors. Some such may possibly be imperfect vegetable productions, whose growth, when completed, might prove them of a different nature. When their smooth surface discharges powdery seeds, they are to be considered as perfect species of *Thelephora*.

THELIGONUM. See THELYGONUM.

THELMENISSUS, in *Ancient Geography*, a town of Asia, in Syria, on an immense plain on the E. of the Orontes, N. of Apamea, and S.W. of Chalcis.

THELONIUUM, TELONIUM, signifies toll.

Among the Romans, *telonium* denoted a custom-house, or place where the toll was collected.

THELONIO, *Breve effendi quieti de*, a writ lying for the citizens of a city, or burghesses of a town, that have a charter or prescription to free them from toll, against the officers of any town or market, who would constrain them to pay it, contrary to the said grant or prescription.

THELONIO *rationabili habendo pro dominis habentibus dominica regis ad firman*, a writ lying for him that hath of the king's demesne in fee-farm to recover reasonable toll of the king's tenants there, if his demesne hath been accustomed to be tolled.

THELOTREMA, in *Botany*, from *θηλη*, a nipple, and *τερυμα*, an orifice, in allusion to the pierced protuberances of the crust; a genus of the order of *Lichenes*, instituted by Acharius, in his *Methodus*, 130. The original type of this genus is *Lichen pertusus* of Linnæus, which is reduced, by the writer of the present article, to ENDOCARPON, (see that article,) in *Prodr. Fl. Græc.* v. 2. 304. The rest of the supposed species may perhaps be in like manner disposed of, or referred to *Urcularia*.

THELPUSA, in *Ancient Geography*. See THALPUSA.

THELSEA. See THALSEA.

THELYGONUM, in *Botany*, a name of very whimsical derivation, concerning which Linnæus has fallen into an error, like professor Martyn and M. De Theis, who have both of them been less penetrating than usual in their enquiries. They all deduce it from *θηλυς*, female, and *γονον*, a joint, or knee; and the last of them supposes the original plant, which was our MERCURIALIS, (see that article,) to have been called *θηλυγονον*, because its swelled joints resembled the knees of a woman. This we modestly presume to be a very unauthorized comparison; and Pliny, from whom the name is borrowed, leads us to a less injurious, if not a wiser, solution. His sapient pages assure us that Arsenogonon (*αρσηνογονον*, or *αρρηνογονον*) was taken to procure male children, its fruit resembling a part of the male organs; while *Thelygonon*, which, though otherwise the same, bore no such fruit, was supposed to cause the production of females. The word therefore is composed of *θηλυς*, and *γονος*, generation, or offspring, *φυλλον*, a leaf, being understood, a confirmation of which may be found under the 6th species of our article MERCURIALIS, above-mentioned. If we may be allowed to play further upon this word, we should remark that its own generation is truly anile. Yet hence arose Bauhin's *Mercurialis testiculata*, *sive mas*, and *spicata*, *sive femina*; appellations perversely bestowed on the two sexes of our *Mercurialis annua*, as well as of *perennis*. How Linnæus came to transfer *Thelygonum* to the genus which now bears it, can no otherwise be accounted for, than from the supposed affinity of the plants to each other, and both having borne the name of *Cynocrambe*, or Dog's Cabbage; a name retained by Gartner, after Tournefort, and liable to no objection, except being composed of one already established, which doubtless caused Linnæus to reject it. The imaginary affinity just alluded to has apparently stamped a poisonous character on the herb before us, which, considering its natural order, is probably undeserved.—Linn. Gen. 494. Schreb. 644. Willd. Sp. Pl. v. 4. 420. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 285. Sm. Prodr. Fl. Græc. Sibth. v. 2. 237. Juss. 405. Lamarck Illustr. t. 777. (Cynocrambe; Tourn. t. 485. Gært. t. 75.)—Class and order, *Monoecia Polyandria*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juss.

Gen. Ch. Male. *Cal.* Perianth of one leaf, turbinate, coloured, cloven half way down into two revolute segments. *Cor.* none. *Stam.* Filaments numerous, from six to twelve

or more, capillary, prominent, as long as the calyx, anthers versatile, linear, straight.

Female, on the same plant, *Cal.* Perianth minute, of two erect, lanceolate, acute, lateral leaves, permanent. *Cor.* none. *Pist.* Germen superior, globose; style lateral, between the calyx-leaves, thread-shaped, much longer than the germen; stigma simple, curved. *Peric.* none. *Seed* solitary, globose, seated on a callous annular receptacle, which falls off with it.

Eff. Ch. Male, Calyx in two revolute segments. Corolla none. Stamens about twelve.

Female, Calyx lateral, of two leaves. Corolla none. Style one. Seed naked, on a deciduous annular receptacle.

1. Th. *Cynocrambe.* Dog's Mercury. Linn. Sp. Pl. 1411. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 941, unpublished. (*Cynocrambe Dioscoridis;* Bauh. Prodr. 59. *C. alfinefolia;* Barrel. Ic. t. 335. *Alfines facie planta nova;* Column. Phyt. 28. t. 30. ed. alt. 120. t. 36.)—The only known species, found in waste ground and the fissures of rocks, especially in shady or moist places, in the south of Europe, as well as in Asia, flowering at almost all seasons. About Rome and Naples it is very frequent. Its seeds may have been brought, from time to time, into our curious botanic gardens, but the plant has no charms, nor any known quality, to render it a popular favourite. The root is annual, simple, cylindrical, with many fibres below. Stems several; spreading or prostrate, a span long, leafy, scarcely branched, round, very smooth and shining, mostly purplish. Leaves alternate, stalked, each with an axillary tuft of smaller ones, ovate, rather succulent, an inch, or thereabouts, in length, of a bright shining green, very smooth on both sides; roughish at the edges. Footstalks almost as long as the leaves, dilated at the base into an annular toothed stipula. Flowers small, whitish, from the bosoms of the upper leaves. The calyx of the males is not unlike the corolla of a honey-suckle in miniature. Seed purplish-brown, furrowed, not much bigger than mustard-seed. The general aspect of the plant evinces its affinity to *Parietaria*, though the flowers in detail are extremely different.—Dr. Sibthorp's figure has but six stamens. We have usually found more, and authors describe from twelve to nineteen.

That this herb is the *κυνια*, or *κυνοκραμβη*, of Dioscorides, there can scarcely be a doubt. He describes it sufficiently well, and informs us that it was sometimes called Wild Male Mercury; which renders the name of *Thelygonum* still more unsuitable; but Linnæus did not always search deeply into such matters, though he will commonly be found quite as learned as most of his critics or correctors. Dioscorides speaks of the plant in question as a gentle purge. This probably caused the *Mercurialis* to be taken with the same intention, though at the peril of the patient's life, as we have already mentioned in its proper place; where also it may be seen that some of the earlier European botanists took that very plant for the *κυνοκραμβη*.

THELYMITRA, from *θηλυ*, female, and *μιτρα*, a diadem, or ornament for the head. This name of Forster's, not one of the most happy, alludes to the cap or hood, ornamented with a pair of plumy tufts, and covering the immediate organs of fructification.—Forst. Gen. t. 49. Swartz Aët. Holm. 1800. 228. t. 3. f. L. Ejusd. in Schrad. Neues Journ. v. 1. 56. t. 1. f. L. Sm. Exot. Bot. v. 1. 55. Brown Prodr. Nov. Holl. v. 1. 314. Willd. Sp. Pl. v. 4. 79. Ait. Hort. Kew. v. 5. 200.—Class and order, *Gynandria Monandria.* Nat. Ord. *Orchideæ.*

Gen. Ch. *Cal.* Perianth of three equal, ovato-lanceolate, coloured leaves, exactly resembling the petals. *Cor.* Petals

two, ovato-lanceolate, the size of the calyx, and exactly like it. Nectary a sessile lip, of the shape, size, and appearance, of the petals and calyx, without a spur. *Stam.* Anther parallel to the stigma, permanent, of two cells close together, attached to the central lobe of a three-cleft hooded appendage to the column; "masses of pollen powdery, pendulous by a thread from the gland of the stigma." Brown. *Pist.* Germen inferior, obovate; style short, united with the hood; stigma in front, obtuse. *Peric.* Capsule obovate, furrowed, with one cell and three valves. Seeds numerous, chaffy.

Eff. Ch. Calyx-leaves coloured, the size and figure of the petals and lip. Column encompassed by a three-lobed hood. Anther parallel to the style, permanent.

1. Th. *Forsteri.* Forster's Thelymitra. Swartz Aët. Holm. 1800. 228. t. 3. f. L, c. Willd. n. 1. (*Th. longifolia;* Forst. Gen. t. 49. *Serapias regularis;* Forst. Prodr. 59.)—Lateral segments of the hood plumous: intermediate one vaulted. Cluster many-flowered.—Gathered by Forster in New Zealand. The stem is above a foot high, round, striated, somewhat spiral, clothed with a few sheathing lanceolate leaves. Cluster terminal, erect, three inches long, of about a dozen upright flowers, scarcely half the size of the next species, each accompanied by an elliptic-lanceolate acute bractea, longer than the partial stalk. Of the colour of the flowers we have no information. Their hood appears, by the dried specimen, as well as Forster's figure, to have its middle segment vaulted, convex, and undivided.

2. Th. *ixioides.* Large-flowered Thelymitra. Swartz Aët. Holm. 1800. 228. t. 3. f. L, a, b, d—g. Willd. n. 2. Br. n. 1. Ait. n. 1. Sm. Exot. Bot. v. 1. 55. t. 29.—Lateral segments of the hood plumous: intermediate one three-cleft; its lateral lobes jagged; central one shortest, cloven, crested at the back. Cluster many-flowered.—Found in the neighbourhood of Port Jackson, New South Wales, from whence we received specimens and drawings about the year 1790. Mr. G. Caley sent out plants to Kew in 1810, but they do not appear to have succeeded there. This is a larger taller species than the foregoing; its flowers above an inch in diameter, very handsome, of a fine blue, spotted, according to Mr. Brown, with a deeper colour. The hood is fringed with hairs, just below the summit, and overtopped by its two lateral, stalked, plumous tufts. The calyx, petals, and lip, spread almost equally in both these, and, we believe, all the following species, except our n. 9, Mr. Brown's *venosa*.

3. Th. *media.* Intermediate Thelymitra. Br. n. 2.—"Outer segments of the hood plumous; intermediate one naked at the back, three-cleft; its central lobe emarginate, half the length of the others. Spike (or cluster?) many-flowered."—Gathered by Mr. Brown, near Port Jackson.

4. Th. *canaliculata.* Channelled Thelymitra. Br. n. 3.—"Outer segments of the hood plumous: intermediate one naked at the back, many-cleft; lobes corrugated; the outer one longest and most remote. Spike many-flowered."—Found by Mr. Brown, in the tropical part of New Holland.

5. Th. *pauciflora.* Few-flowered Thelymitra. Br. n. 4.—"Hood half the length of the petals: its outer segments plumous: intermediate one naked at the back, emarginate, with rounded entire lobes. Spike of few flowers."—Gathered by Mr. Brown, near Port Jackson.

6. Th. *nuda.* Naked Thelymitra. Br. n. 5.—"Hood half the length of the petals; its outer segments plumous; intermediate one naked at the back, emarginate, with rounded entire lobes. Spike many-flowered."—Gathered in the island of Van Diemen, by Mr. Brown. By the above definition,

nition, this species differs from the last only in having more numerous flowers.

7. *Th. angustifolia*. Narrow-leaved Thelymitra. Br. n. 6.—“Outer segments of the hood plumous; intermediate one naked at the back, emarginate, with toothed lobes. Spike of few flowers. Leaf as tall as the flower-stalk.”—Found by Mr. Brown, in the neighbourhood of Port Jackson.

8. *Th. carnea*. Flesh-coloured Thelymitra. Br. n. 7.—“Calyx and petals spreading. Outer segments of the hood finely toothed, beardless. Stalk with one or two flowers.”—Found by Mr. Brown, near Port Jackson. A drawing in our possession, which seems to belong to this species, represents the stalk about four inches high, with a light-red terminal flower, above an inch wide, and a few short, radical, lanceolate leaves.

9. *Th. venosa*. Veiny Thelymitra. Br. n. 8.—“Calyx and petals converging. Outer segments of the hood beardless, spirally involute.”—Gathered also near Port Jackson, by Mr. Brown.

10. *Th. tigrina*. Tiger-spotted Thelymitra. Br. n. 9.—“Lateral segments of the hood distinct, with tufted beards; intermediate one shorter, crested. Leaves linear, channelled.”—Discovered by Mr. Brown, on the south coast of New Holland. The flowers are yellow, with darker spots.

11. *Th. fusco-lutea*. Brownish-yellow Thelymitra. Br. n. 10.—“Lateral segments of the hood converging, connected, fringed; intermediate one erect, naked. Leaves lanceolate.”—Gathered by Mr. Brown, in the same country with the *tigrina*. He describes the yellow colour of the flowers as peculiar to these two last species; all the rest, as far as hitherto discovered, having them generally blue, sometimes white, or flesh-coloured. We have necessarily, for want of authentic specimens, except of the first two species, adopted the specific characters of the excellent author whose name we have cited.—He establishes a genus under the name of *EPIBLEMA*, which appears to differ from *Thelymitra*, in having a stalked lip with tufts of fibres at its base; an appendage to the base of the column, connected with the claw of the lip underneath; and the anther accompanied at each side by a petal-like lobe. Of this there is only one species, *E. grandiflorum*, found on the south coast of New Holland. Its flowers are large, blue, and handsome.

THELYPHONON, from *θηλυς*, female, and *φονος*, murder, or destruction, the name of an herb mentioned by Pliny, book 25, chap. 10, which he says is by some called Scorpion, from the resemblance of its root to a scorpion, and the touch of which is fatal to that animal, as a remedy for whose sting it is given internally. He adds, that the same root kills any sort of quadruped, if applied to the parts of generation; and that its leaf, which resembles that of *Cyclamen*, produces the same effect within the course of a day. His description answers to the *Doronicum scorpioides*, Willd. Sp. Pl. v. 3. 2114; *D. latifolium*, Clus. Hist. v. 2. 16; Great Leopard's-bane, Ger. Em. 759; but there is apparently much superstition, mistake, or exaggeration, intermixed in his relation.

THELYPTERIS, from *θηλυς*, female, and *πτερις*, a fern, a name by which Pliny designates a species of the Fern tribe, whose habit appears to be more delicate than that of his *Filix mas*, or Male Fern. The latter should seem, by his description, to be our *Pteris aquilina*. (See **PTERIS**.) The name of *Filix mas*, however, has remained with a large species of *Aspidium*, Sm. Fl. Brit. 1121. Engl. Bot. t. 1458; and that of *Filix femina* with a more slender and finely-divided one of the same genus, Engl. Bot. t. 1459; while a third, whose texture is more thin and tender than either, has received the appellation of *Aspidium Thelypteris*. They were all referred by Linnæus, under the same specific names, to

POLYPODIUM. (See that article.) Our present *Thelypteris*, therefore, must not be taken for that of Pliny, being rather a north-country plant, not hitherto noticed in Greece by any botanical traveller.

THEMA, in *Ancient Geography*, a town of Syria, in the Chalibonitide territory; and also of Arabia Deserta.

THEMAN, a town of Arabia Petræa, 5 miles from Petra, which had a Roman garrison.—Also, a town of Judea, in the half-tribe of Manasseh, on the other side of Jordan; famed for the wisdom of its inhabitants. Eliphaz, one of Job's three friends, came from this place.

THEMAR, in *Geography*, a town of Germany, in the county of Henneberg, on the Werra; 12 miles S.E. of Meiningen.

THEME, **THEMA**, a subject or topic, upon which to write or compose.

THEME, among *Astrologers*, denotes the figure they construct when they draw the horoscope; representing the state of the heavens for a certain point, or moment, required; *i. e.* the places of the stars and planets for that moment.

The celestial theme consists of twelve triangles, inclosed within two squares, and called the *twelve houses*.

THEME, in *Grammar*, denotes a verb, considered in its primary and absolute sense, and not limited to any particular mode or tense: or it is the verb in its primitive radical state, whence its different formations are derived.

THEME, in *Music*; *Thema*, Lat.; *Tema*, Ital.; *Motivo*, *Soggetto*, is a series of notes selected as the text or subject of a new composition, or an old favourite and well-known air to grace and embellish with variations. About the middle of the last century, the musical world was overwhelmed with dull, unmeaning, and monotonous variations to old and new tunes, which consisted of nothing more than a regular multiplication of notes, without fancy, taste, or harmonical resources; till Haydn, in the slow and graceful middle movements of his quartets and symphonies, by a richness of imagination, by double counterpoint, and inexhaustible resources of melody and harmony, rendered variations the most ingenious, pleasing, and heart-felt of his admirable productions à grand orchestra; and Mozart, in a totally different style, and for a totally different purpose, has rendered little favourite French, Italian, German, and English airs the most beautiful, amusing, and useful compositions for the piano forte that have ever been produced since the invention of that instrument. More than twenty of these have been printed in England that were brought from Vienna by Mrs. Peploe, who played them, as she did all other music, with a firmness, accuracy, and spirit, which neither dilettante nor professor has ever exceeded.

These themes seem to have been a series of lessons, composed expressly to form the hand and taste of some disciple of the author, who promised to be a great performer. In every one of these themes, there are some peculiar difficulties of execution, refinement, and expression to vanquish, at which it is in vain for mediocrity to aspire.

THEMEDA, in *Botany*, a genus of grasses, so called from its Arabic name *Thamed*.—Forsk. Ægypt-Arab. 178. Juss. 447.—It is found in Yemen, near Hadie. Forkall names the only species *T. triandra*, and describes it as follows.

—“A polygamous grass. *Spikelets* proceeding from a sheath, capitate; the outer ones whorled, male. *Calyx* of one valve, single-flowered. *Corolla* of two valves. *Styles* and *awns* wanting. In the middle of the head of flowers arises a short stalk, bearing two stalked male *spikelets*, and a sessile hermaphrodite one; the *calyx* is of one valve, *corolla* of two; *awn* proceeding from the receptacle, much longer than the flower.

Stems racemose. Sheaths compressed, broad, sword-shaped, concealing the branches, and the heads of flowers, before expansion. All the heads are originally concealed in the sheath of a leaf."

This can only be the Linnæan *Anthistiria*, a genus which Mr. Brown, in his *Prodr. Nov. Holl.* v. 1. 200, asserts to have been first described by Forskall, but he gives no reference to the *Themeda*, which omission has caused us much trouble, and after all, leaves the matter in some uncertainty. Desfontaines, in his *Fl. Atlant.* v. 2. 380, has reformed the character of *Anthistiria*, and has given a figure, t. 254, of *A. glauca*, called by some authors *Stipa paleacea*, which agrees, as nearly as possible, with Forskall's description. It does not appear that Vahl, Willdenow, or any other author, has adverted to *Themeda*, except Jusseu, who has merely admitted it, on Forskall's authority, into his appendix, without examination or elucidation.

We presume here to observe, that every correct writer ought invariably to cite the page of his author; especially in referring to a confused posthumous work, without an index, like that of Forskall.

THEMIS, in *Ancient Geography*, a town of Africa Pro-pria, situated between Tabraca and the river Bagradas.

THEMIS, in *Geography*, a river of Transylvania, which runs into the Alaut, near Marienburg.

THEMIS, in *Astronomy*, a name given by some to the third satellite of Jupiter.

THEMIS, in *Mythology*, the daughter of Cœlum and Terra, or of Uranus and Titaia, the eldest sister of Saturn, and aunt of Jupiter.

Themis, according to Diodorus, established divination, sacrifices, the laws of religion, and every regulation that contributed to maintain order and peace among men. She also applied herself to astrology, issued predictions, and after her death temples were erected to her, in which oracles were delivered. She had a temple on mount Parnassus, and another in the citadel of Athens.

THEMISCYRA, in *Ancient Geography*, a town of Asia Minor, in the kingdom of Pontus, situated in the open country to which it gave name, upon the banks of the river Thermodon, towards its mouth in the Euxine sea. Diodorus Siculus says that it was a royal city of the Amazons, and that they founded it.

THEMISONIUM, a town and country of Asia, in Phrygia.

THEMISSUS, a town of Asia Minor, in Caria.

THEMISTEAS, a promontory of Asia, in Carmania.

THEMISTIUS, surnamed *Euphrades*, or the fine speaker, in *Biography*, an Eclectic philosopher, was born in an obscure village of Paphlagonia, about the year 317, and having fixed his residence at Constantinople, taught eloquence and philosophy with great reputation and success. His disciples, both Pagan and Christian, were numerous; to the former class belonged Libanius, and to the latter, Gregory Nazianzen. By the emperors he was highly esteemed, and they conferred upon him distinguished honours. In the year 355, Constantius admitted him into the senate; and in return for an eloquent eulogium, presented him with a brazen statue. Julian corresponded with him as a friend; and in 362, appointed him præfect of Constantinople. His character and eloquence induced other emperors to bestow upon him peculiar favours. When Jovian issued his edict of toleration, Themistius was deputed by the senate to express its loyalty; and on this occasion he expatiated with elegance and liberality on the rights of conscience, and the independence of the human mind. Of his candour and liberality, the following mem-

orable instance is recorded by Socrates, Sozomen, and other ecclesiastical historians. The emperor Valens, who favoured the Arian party, treated the Trinitarians with great severity. Themistius, disapproving the measures which the emperor pursued, addressed him in an eloquent speech, stating that the diversity of opinions among Christians was inconsiderable, compared with that of the Pagan philosophers; and urging upon his attention, that this diversity could not be displeasing to God, since it did not prevent men from worshipping him with true piety. By such arguments, Themistius, it is said, prevailed upon the emperor to treat the Trinitarians with greater lenity. What an example does this Pagan philosopher exhibit even to Christian divines! In the year 376 Themistius visited Rome, but though solicited to take up his abode there, he preferred returning to Constantinople. It redounds very much to the honour of this philosopher, and also to the liberal sentiments of Theodosius the Great, that during his visit to the Western empire, the emperor entrusted Themistius, notwithstanding difference of religion, with the care and education of his son Arcadius. Themistius was no less distinguished by gentleness of temper and urbanity of manners, than by his eloquence and wisdom, and ability in the conduct of public affairs. After a long course of civil honours, he withdrew about the year 387, at an advanced age, from public business; and soon after died. Themistius, the subject of this article, who does not appear to have ever deserted the Pagan schools, should be distinguished from a Christian deacon of the same name, who lived after the council of Chalcedon, held in the year 551, and who was the head of the sect called *Agnostæ*; which see. As a philosopher, Themistius illustrated several of the works of Aristotle, particularly the *Analytics*, the *Physics*, and the book on the *Soul*, in commentaries, written with great perspicuity and elegance. His "Orations," which were thirty-six, and of which thirty-three are still remaining, are strongly marked with the same characters. The best editions of his Orations are those of Petau, Gr. and Lat. Paris, 4to. 1618; and of Hardouin, Gr. and Lat. Paris, fol. 1684. Fabr. Bib. Græc. Brucker by Enfield. Gibbon. Lardner's Works, vol. viii.

THEMISTOCLES, an Athenian statesman and commander, the son of Neocles, a person of middle rank at Athens. At a very early age he manifested, both in his amusements and in his literary pursuits, those views and inclinations, which marked the character and destiny of his maturer years. To those who ridiculed him on account of his apparent contempt of ornamental accomplishments, he replied, "It is true, I never learned how to tune a harp, or play upon a lute; but I know how to raise a small state to a great one." Ambition seems to have been his ruling passion, and he lost no opportunity of acquiring military and political distinctions. He sought popularity with a view to his personal advancement; and less pure and disinterested in his principles than Aristides, his solicitude for the glory of his country was subservient to his own reputation and eminence. After the defeat of the Persian invasion by the battle of Marathon, an event which interested his feelings and roused into exercise his predominant love of glory, he foresaw that the attempt might be renewed by sea as well as by land; and he therefore exerted his influence in rendering the Athenian state a naval power. With this view, he induced his countrymen to appropriate the revenue accruing from the silver mines to the equipment of a number of galleys; and as he possessed the chief authority at Athens, in consequence of the banishment of Aristides, he found no obstacle to the execution of his design. In the course of three years after this event, the hostile preparations of Xerxes for an expedi-

tion into Greece to enforce the demand of subjection, furnished him with a plea for urging the Grecian states to compromise their mutual dissensions, and to unite in defending themselves against the invader. In the choice of a general, with whom the command should be intrusted in this emergency, the Athenians favoured the claims of a democratical orator, named Epicydes, who had fascinated them by his eloquence; but Themistocles induced him to surrender his pretensions to an office for which he was totally unqualified by a bribe, and thus secured the appointment for himself without a competitor. When news arrived that the Persian army, conveyed by a fleet, was approaching the straits of Thermopylæ, Themistocles proposed that the Athenians should fit out their galleys and sail to meet them; but this counsel being rejected, he took the command of their troops, and having joined the Lacedæmonians, marched towards Tempé. In the mean while, intelligence was received that the passage of the straits had been forced, and that Bœotia had submitted to the invaders; and upon this alarm the army returned without seeing the enemy. In these circumstances of apprehended danger, the Athenians, according to their customary practice, had recourse for counsel to the Delphic oracle. The answer, probably suggested by Themistocles himself, was, that they should rely solely on their fleet. It was now proposed, that the city should be wholly abandoned to the Persians, without any attempt for its defence; that the women, children, and aged should be removed to some place of security; and that all who were able to bear arms, should embark on board the galleys, and watch the event. A decree was obtained, after much fruitless opposition, to this purpose; and this was followed by another, which permitted all exiled citizens to return. Aristides was one of this number, who nobly sacrificing, in the moment of his country's danger, all private animosities, concurred in all the spirited measures of his former rival.

Eurybiades, a Spartan, to whom the command of the confederate fleet was assigned, and who was very unequal to the office, differed with Themistocles as to the measures proper to be pursued; and behaved with an insolence, which, probably for the sake of the public service, the latter did not think proper to resent. Eurybiades was pacified by the gentleness and self-command of Themistocles, and convinced by his reasoning. Finding it prudent, however, to change the measures which he originally contemplated, he employed a stratagem to induce the Persians to advance and make an attack. This was followed by the famous battle of Salamis, which took place in the year B.C. 480, and which terminated in the signal defeat of the Persian navy. The victory has been chiefly ascribed to the skill and valour of Themistocles; and having thus succeeded, he advised the confederates to sail immediately to the Hellespont, in order to destroy the bridge of boats by which the army of Xerxes had passed over, and thus to intercept his communication with Asia; but being overruled in this proposal, he dispatched a secret messenger to the Persian king, with information that the Greeks intended to break his bridge, and advising him to retreat immediately before the design was executed. The policy of Themistocles, as we may judge from this instance, was not always uniform and consistent; and in another case, which remains to be mentioned, on the authority of Plutarch, it was inexcusably flagitious. When the combined Grecian fleet was wintering at Pegasa in Magnesia, he informed the Athenians, that he had conceived a project which would be of infinite service to the republic, and at their desire, he would communicate it to Aristides. This virtuous man told them, that the scheme of Themistocles would be highly advantageous, but that nothing could be

more unjust; upon which, very much to their honour, they determined not to adopt it. The plan was to burn all the ships of the fleet, except those of Athens, by which she would remain complete mistress of the seas.

The victory at Salamis advanced the name and character of Themistocles to the highest pitch of glory throughout Greece. On his visit to Sparta, he was received with every token of respect; and whilst the first prize of valour was decreed by the people to their countryman Eurybiades, the olive wreath of superior wisdom was placed on the head of the Athenian; and they also presented him with a magnificent chariot, and ordered three hundred of their youth to attend him back to the borders. At the next Olympic games, the eyes of the whole assembly were fixed upon Themistocles, and he was pointed out to strangers as the most interesting object at the spectacle. Themistocles himself acknowledged, that this was the noblest day of his life. When the constitution of Athens was about to be re-established, after the rebuilding of the city, Themistocles, in conformity to the political principles which he had adopted, proposed that every citizen should have an equal right to participate in the government, and that the members should be chosen from the body of the people, without distinction; and in his proposals the people unanimously acquiesced. He also proposed to fortify the city; but as the Lacedæmonians objected to the proposal, he was deputed upon an embassy to Sparta with a view of conciliating them. He contrived, however, by various artifices, to prolong the negotiation, so that the Athenians had constructed their walls before the Spartans were duly apprized of the fact. Themistocles vindicated this artifice by alleging, "that all things are lawful in serving our country;" and the Spartans, admiring his patriotism, silently acquiesced. In the following year, his scheme for rendering the Pyræum the principal port of Athens, and connecting it with the city by long walls, was adopted and accomplished.

Independently of the deceits which Themistocles had practised with regard to the Lacedæmonians, another circumstance had occurred which increased their enmity against him. He had successfully opposed their sending deputies to the Amphictyonic council, and thus degraded their authority in Greece. Incensed against him, they joined his rivals at Athens, and used all their influence to destroy his reputation. His own conduct also had excited jealousy and resentment; for he had caused to be erected near his own house a temple to "Diana Aristobule," or "of the best counsel," thus intimating, that his counsels had been the best for the Grecian community. His enemies prevailed, and procured his banishment from Athens by the sentence of Ostracism. During his exile at Argos, his enemies gained an additional advantage over him. Apprized of the treasonable designs of Pausanias, the Spartan, against the liberty of Greece, he declined the disclosure of them; and after the detection and death of Pausanias, letters of Themistocles were found, which proved that they had conferred on this business. The Lacedæmonians preferred an accusation against him to the Athenians; and they called him to account in the presence of the states of Greece. Dreading a trial, he fled to Corcyra, and thinking himself insecure there, he withdrew to Epirus: and at length was reduced to the necessity of seeking the protection of Admetus, king of the Molossi, whom he had formerly offended. The vengeance of the Spartans pursued him, and Admetus was threatened with a war, if he protected the criminal. The king dismissed him with money across the continent to a port in the Ægean sea, whence he reached Asia in safety. In the year B.C. 462, he arrived at the Persian court; but here

his name was so obnoxious, that a reward of 200 talents had been offered for apprehending him. Here he appeared in disguise, and pretending that he had important information which he wished to communicate to the king in person, he was admitted to the royal presence, and favourably received: the 200 talents, which were the price of his head, were paid to himself, and a more ample recompence was offered to him, if he would give useful information concerning Greece. He was granted time for acquiring the Persian language, and after a year he appeared at court like a native. The king and royal family treated him with distinction; and it is said that the revenues of three cities, viz. Magnesia, Lampfacus, and Myus, were assigned him, under the name of bread, wine and meat; and as some say, two more, for lodging and wardrobes. In this state of luxury and magnificence he was joined by the members of his family, who had been conveyed to him by his friends, and to them he expressed a kind of satisfaction with his condition, which proves that moral meanness may accompany exalted talents.

The close of his life is involved in obscurity. Plutarch relates, that upon the revolt of Egypt, supported by the Athenians, against the Persian dominion, the Greek king, resolving to send an expedition into Greece, dispatched an order to Themistocles at Magnesia, reminding him of his promises, and claiming the fulfilment of them: upon which it is said, that, in order to avoid the disgrace of bearing arms against his country, after sacrificing to the gods and taking solemn leave of his friends, he drank poison, and died in that city at the age of sixty-five years. Thucydides, his contemporary, says that he died of a distemper; and others again report, that he poisoned himself, because it was not in his power to accomplish what he had promised. The Magnesians honoured his memory with a sumptuous tomb; but his remains, according to his own orders, were privately conveyed to Attica, where they were interred. It is further said, that the Athenians, repenting of their treatment of him, raised a tomb for him in the Pyræum, which was an interesting object to all who visited that port. His singular talents, and the services which he rendered to his country, must be acknowledged; and those who think favourably of him, ascribe his desertion of them to unjust persecution. But in Themistocles we look in vain for the virtues of an Aristides; and he can only be allowed the honour of a distinguished general and statesman. Thucydides. Plut. in Them. Ancient Un. Hist.

THEMNA, **TIMNA**, or *Thamnata*, in *Ancient Geography*, a town of Palestine, in the tribe of Dan. Josh. xix. 43.—Also, a town of Arabia Deserta, on the confines of Mesopotamia.

THEN, in *Geography*, a river of France, which runs into the Weze, near Francremont.

THENA, in *Ancient Geography*, an ancient town of Africa, situated N.E. of the Tanais and near it, and two miles in circuit.—Also, a town of Samaria, in the vicinity of Sichem.

THENAC, or **THANAC**, a royal town of Judæa, in the half-tribe of Manasseh, on this side of Jordan. It was given to the Levites of this tribe, and its king was one of those who were vanquished and slain by Joshua.

THENÆ, a town of the isle of Crete, near Cnossus.

THENAR, in *Anatomy*. The eminence in the palm of the hand, formed by the muscles of the thumb, has been called thenar: and some of the muscles have been described under the same name.

The thenar of Riolan and Winslow includes the abductor pollicis brevis, and the opponens pollicis.

THENEATE *el Gammim*, the *Sheep Cliffs*, in *Geogra-*

phy, mountains of Africa, in Sahara; 90 miles S. of Algiers.

THENEZAY, a town of France, in the department of the Two Sevres; 10 miles N.E. of Partenay.

THENGEN, a town of Germany, which gives name to a principality, situated in the Hegau, bordering on Schaffhausen; 8 miles N. of Schaffhausen.

THENON, a town of France, in the department of the Dordogne; 6 miles N.W. of Montignac.

THENONGOUN, a town of the Birman empire; 4 miles S.W. of Ava.

THENOPSYCHITES. See **THNETOPSYCHITES**.

THENSA, among the Romans, a veil or canopy, used in the chariots of games; and likewise to cover a seat of state.

Thenæ could not be granted to any but by the express allowance of the senate. Hist. Acad. Inscript. vol. i. p. 359.

THEOBALD, **LEWIS**, in *Biography*, a professed writer, was the son of an eminent attorney at Sittingbourn, in the county of Kent, and is here noticed as one of the numerous editors of Shakspeare. Of his various works, critical, poetical, and dramatic, it is needless to give any account, as they have sunk into oblivion. He had the misfortune of becoming, to an undue degree, the object of Mr. Pope's contempt and satire, and of having the first place assigned him in the Dunciad, though he was afterwards superseded by Cibber. His edition of Shakspeare was preceded by a work entitled "Shakspeare restored," and published in 1726; and also by that of Mr. Pope. It is thus characterized by Dr. Johnson: "Pope was succeeded by Theobald, a man of narrow comprehension and small acquisitions, with no native and intrinsic splendour of genius, with little of the artificial light of learning, but zeal for minute accuracy, and not negligent in pursuing it. He collated the ancient copies, and rectified many errors. A man so anxiously scrupulous might have been expected to do more; for what little he did was commonly right." Of the tragedy which he brought on the stage, and which is entitled "The Double Falsehood," the greater part is ascribed by him to Shakspeare; but Dr. Farmer has proved that this is a mistake.

THEOBROMA, in *Botany*, the Chocolate-tree, received that name from Linnæus, who probably, like the president Bachot, cited by De Theis, was fond of the delicious produce of this tree; for the word is formed of θεος, a god, and βρωμα, food. A French writer, M. Tussac, in his magnificent Flore des Antilles, has objected to the above generic name, for a reason which we confess to have been one of the last we should have thought of; that "it carries with it the signification of a quality, and seems therefore more fit for the name of a species." Surely nothing can be more desirable than a generic appellation which conveys information; on which account *Amaranthus*, *Artocarpus*, *Biferrula*, are excellent; we need not run through the botanical alphabet in search of numerous others. Such probably was the origin of most names, in every language, and who can tell that the American word *Cacao*, substituted, or rather restored, by Tussac, may not express some quality of the plant? Neither is it an objection to any significative generic names, that they express merely some general property or peculiarity, not found in every one of the species, witness *Urtica*. The idea of stinging is associated with the name of a Nettle; like redness with that of a Rose; though there are Dead Nettles, and White Roses.—Linn. Gen. 391, with an erroneous description, corrected in Linn. Suppl. 341. Schreb. 513. Willd. Sp. Pl. v. 3. 1422. Mart. Mill.

Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 408. Juss. 276. Lamarek Illustr. t. 635. (Cacao; Tourn. t. 444. Gærtner. t. 122.)—Clas and order, *Polyadelphia Decandria*. Nat. Ord. *Columnifera*, Linn. *Malvaceae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five ovato-lanceolate, acute, spreading, coloured, deciduous leaves. *Cor.* Petals five, rather longer than the calyx; their claws dilated, concave, hooded, marked internally with two ribs from the base, and one from the summit: their borders roundish-ovate, pointed, spreading, each contracted at the base into a narrow, erect and recurved stalk, connected with the claw. Nectary short, cup-shaped, crowned with five long, erect, awl-shaped, pointed, equal, converging segments. *Stam.* Filaments five, thread-shaped, erect, recurved at the upper part, concealed in the hollow claws of the petals, inserted into the outside of the nectary between its segments, but not above half so long; anthers two to each filament, (one on each side, at the summit,) vertical, two-lobed, one lobe over the other. *Pist.* Germen superior, nearly sessile, ovate, with five furrows; style cylindrical; stigma in five awl-shaped segments. *Peric.* Berry elliptic-oblong, beaked, coated, of one cell. *Seeds* large, ovate, smooth, numerous, in five rows; their cotyledons in many deep lobes.

Ess. Ch. Calyx of five leaves. Petals five, vaulted at the base. Nectary cup-shaped, with five taper points. Anthers two to each filament. Stigma five-cleft. Berry coated. Seeds ovate.

Obf. Gærtner observes that he could find no traces of the five cells attributed by authors to this fruit. It is probable, however, from analogy, that they may exist in the germen, and Aublet's account is sufficiently explicit of their presence in the fruit. The drawing in the Linnæan herbarium, which appears to have been sent by Allamand from the West Indies, has led us to suppose each filament bore four anthers; but it seems there are only two, each of two round, distinct, vertical lobes, as represented by Aublet, t. 275, and copied by Lamarek. The order of *Decandria* must therefore be restored in the class *Polyadelphia*. See Sm. Intr. to Bot. ed. 3. 340. Linnæus's characters of *Theobroma* in Gen. Pl. were taken chiefly from Plumier's *Guazuma*, the *BUBROMA* of Schreb. Gen. 513; see that article. He has left a more correct description in manuscript, from which perhaps his son composed what is given in the *Supplementum*. From these sources, with the help of Allamand's drawing, and what is to be found in Aublet and Schreber, we have drawn up our account, having no opportunity of examining a flower.

1. *Th. Cacao*. Smooth-leaved Chocolate-tree. Linn. Sp. Pl. 1100. Suppl. 341. Willd. n. 1. Ait. n. 1. (*Th.* n. 2 and 3; Browne Jam. 306. Cacao; Merian. Surin. t. 26 and 63. *C. Theobroma*; Tuffac Flore des Antilles, t. 13. *Arbor cacavifera americana*; Pluk. Almag. 40. Phyt. t. 268. f. 3.)—Leaves entire, smooth on both sides.—Native of South America. Miller appears to have had this plant alive at Chelsea, but it has never long succeeded in our stoves; being extremely tender, even in some parts of the West Indies. Browne says the Chocolate-trees, though naturalized in the woods of Jamaica, are very delicate, and rarely survive when once they are loosened in the ground by hurricanes. (See CHOCOLATE.) These trees are the size of a middling apple-tree, but seldom exceed six or seven inches in diameter. They are very beautiful, especially when laden with fruit, which is dispersed, on short stalks, over the stem, and round principal branches; its yellow hue and warty surface somewhat resembling a citron. The leaves are alternate, stalked, drooping, a foot long, and three inches broad, elliptic-oblong, pointed, entire, slightly wavy,

very smooth on both sides, with one mid-rib, and many transverse ones, connected by innumerable, minute, reticulated veins. *Footstalks* round, hairy, an inch long. *Stipulas* minute, deciduous. *Flowers* small, several together in tufts, at the sides of the branches, on simple stalks, only one in each tuft, commonly producing fruit. *Calyx* light rose-coloured. *Petals* yellow.

2. *Th. guianensis*. Downy-leaved Chocolate-tree. Willd. n. 1. Ait. n. 1. (Cacao guianensis; Aubl. Guian. v. 2. 683. t. 275.)—Leaves wavy, and somewhat toothed; downy beneath.—Native of marshy woods in Guiana, bearing flowers and fruit in September. Of rather more humble growth than the foregoing. The leaves are, at most, but eight inches in length, and three in breadth; their margin wavy, or rather bordered with shallow teeth, towards the extremity; their upper surface smooth and green; the under clothed with short, ash-coloured, or rusty pubescence, and reticulated with fine veins. *Footstalks* short, channelled, downy. *Flowers* situated like the former. *Calyx* green without, yellow within. *Petals* yellowish. *Fruit* elliptical, with five angles, and clothed with short rusty down. Aublet says it has five cells, separated by membranous partitions; the seeds enveloped in a gelatinous, white, melting substance; their kernel white, very good eating when fresh. He speaks of this species as the Chocolate of Guiana, though he mentions a *Cacao sativa*, with entire leaves, as a cultivated kind, under which he cites *Theobroma Cacao* of Linnæus, and its acknowledged synonyms.

Aublet has also a *Cacao sylvestris*, v. 2. 687. t. 276, with entire leaves, downy beneath, and a downy fruit, without ribs. Willdenow asserts, we know not on what authority, that this last is *Duroia Eriopila*, Linn. Suppl. 209, of which we, unfortunately, have met with no specimen. A branch of Aublet's plant, communicated from his own herbarium by Sir Joseph Banks, appears a variety of the last, its leaves being obscurely toothed in a similar manner; but for want of flowers we cannot say how far it answers to *Duroia*, between which and *Theobroma* there is no affinity in that respect. Aublet clearly describes his as a *Theobroma*, and we cannot help suspecting some error in Willdenow; as well as, possibly, a disagreement between Aublet's figure and our above-mentioned specimen, which latter may be, as above hinted, his *Cacao guianensis*. At any rate, the two species of *Theobroma* which we have described, are certainly and permanently distinct.

THEOBROMA, in *Gardening*, contains a plant of the exotic tree kind, of which the species usually cultivated is the chocolate nut-tree (*T. cacao*).

In its natural state, this tree produces a nut or fruit which is smooth, of a yellow, red, or of both colours, about three inches in diameter: it has a fleshy rind, near half an inch in thickness, which is flesh-coloured within: the pulp being whitish, of the consistence of butter, separating from the rind in a state of ripeness, and adhering to it only by filaments, which penetrate it, and reach to the seeds. Hence it is known when the seeds are ripe by the rattling of the capsule when it is shaken: the pulp has a sweet and not unpleasant taste, with a slight acidity; it is sucked and eaten raw by the natives; it may be easily separated into as many parts as there are seeds, to which it adheres strongly, and they are wrapped up in it, so that each seed seems to have its own proper pulp: the seeds are about twenty-five in number: when fresh, they are of a flesh-colour: gathered before they are ripe, they preserve them in sugar, and thus they are very grateful to the palate: they quickly lose their power of vegetation, if taken out of the capsule, but kept in it, they preserve that power for a long time: the tree bears

bears leaves, flowers, and fruit all the year through; but the usual seasons for gathering the fruit are June and December: in two years from the seed, the tree is above three feet high, and spreads its branches, not more than five of which are suffered to remain. Before its third year is complete, it shews for fruit; a tree yields from two to three pounds of seed annually. Such trees are of course very productive.

Method of Culture.—It is increased by seed obtained from abroad, sowing it as soon after its arrival as possible, in pots filled with light earth, and plunging them in a bark-bed, where they will soon come up; and when the plants are about three inches high, potting them off separately, and replunging them in the bark-bed in the stove, managing them as other woody exotics of the stove kind afterwards. They afford an agreeable variety in stove collections.

This tree is cultivated to considerable extent, and with very great attention in its native situations in the hot parts of America, for the sake of its fruit, the kernels of which are much used in the making of chocolate there, as well as in this country. In this intention, they are first brought to a pulverizable state by drying or roasting in a proper apparatus; they are then reduced into a fine powder by mills or other contrivances: after which, this fine powder is wrought up into a paste with orange-water, milk, and other liquids, and has sugar, different sorts of aromatic spices, and some aromatic perfumes, mixed and incorporated with it, when it is formed into cakes, or made into pretty large rolls, for exportation and sale in the European and other markets, if prepared in the places of its native growth.

It is employed somewhat in the manner of coffee as a fine rich breakfast article of diet, and used pretty extensively for that purpose in this and some other countries.

THEOCATAGNOSTÆ, formed from $\Theta\epsilon\omicron\varsigma$, *God*, and $\kappa\alpha\tau\alpha\gamma\iota\nu\sigma\tau\iota\kappa\iota$, *I judge, or condemn*, a sect of heretics, or rather of blasphemers, who presumed to find fault with certain words and actions of God, and to blame many things in the Scriptures.

Marshal, in his Tables, places these heretics in the seventh century; for what reason we know not. Damascenus is the only author that mentions them, but without taking any notice of the time of their appearance.

THEOCRACY, formed from $\Theta\epsilon\omicron\varsigma$, *God*, and $\kappa\rho\alpha\tau\omicron\upsilon$, *power, empire*, a state governed by the immediate direction of God alone.

According to Josephus, the ancient government of the Jews was theocratic; God himself ordering and directing every thing belonging to the sovereign authority.

By the oracle of Jehovah himself, all laws were enacted, war was proclaimed, and magistrates were appointed; in which three particulars the *summa potestas*, or sovereign authority, of any state, consists. And as Jehovah was the king, as well as the God of Israel, the priests and Levites, who were the stated attendants on his presence, and to whom the execution of the law in many cases was committed, were properly ministers of state and of civil government, as well as of religion. The sacrifices also, beside their religious use, were intended for the support of the state, and civil government.

This theocracy lasted till the time of Saul; when the Israelites, weary of it, desired they might have a king like other nations; and thence forward the state became monarchic.

There was also a kind of imaginary theocracy at Athens: while the sons of Codrus were disputing the succession, the Athenians, wearied out with the miseries of an intestine war,

abolished the royalty, and declared Jupiter the only king of the people at Athens.

THEOCRITUS, in *Biography*, a Greek poet, esteemed as the model of pastoral poetry, was a native of Syracuse, and the son of Praxagoras and Philina. The time in which he flourished is ascertained by two of his poems, one addressed to Hiero, king of Syracuse, who began his reign about the year B.C. 265, and the other to Ptolemy Philadelphus, whose reign comprehended the interval between 281 and 246 B.C. Although Hiero is reported to have been a patron of literature, persons of rank, as we may infer from Theocritus's poem, did not follow his example, at least in granting encouragement to poets; and therefore Theocritus left Sicily, and visited the court of Ptolemy Philadelphus at Alexandria, on whom he pronounces a splendid eulogy. The compositions of this poet are denominated "Idylls;" they are written in the Doric or rustic dialect, and few of them are pastorals, though most of them relate to rural life and manners. The purely pastoral are distinguished by the truth and simplicity of the manners, descending sometimes even to coarseness, and the pleasing description of natural objects, drawn from the life. To those who have a taste for genuine simplicity, and the beauties of nature, says one of his biographers, the poetry of Theocritus is highly agreeable. The most esteemed editions of his works, are D. Heinsius's, 4to. Commel. 1604; R. Weil's, Oxon. 8vo. 1699; Th. Warton's, Oxon. 2 vols. 4to. 1770; Valkenaer's, cum Bione et Moscho, Lugd. Bat. 8vo. 1779. Suidas, Vossius. Gen. Biog.

THEODOLITE, or **THEODOLET**, is an instrument used for measuring horizontal and vertical angles in land-surveying. This instrument was at first made on a small portable scale, supported by a tripod that will shut up into the form of a walking-stick, when the mechanism of brass-work is dismounted: and the state of dividing circles is now brought to that perfection in England, that small portable theodolites are still in use among land-surveyors, who confine themselves to the planning of single estates, for which these instruments are competent; but for surveys on a large scale, such as county surveys, or trigonometrical measurement of distant stations, theodolites of an enlarged construction have been used with corresponding advantage. Out of the numerous modifications of this instrument, that different artists have contrived, we propose to select two for particular description, which are generally considered as the best for accurate surveys; one by Ramsden, and the other by Troughton. We will begin with that large instrument already referred to in a former article, which was made by Ramsden, in the year 1777, for the use of general Roy, when he undertook his grand trigonometrical operations, and which is described in the 80th vol. of the Philosophical Transactions of London (1790), with all the constituent parts given separate in four large plates. A similar instrument, by the same maker, has since been used for the grand general survey of the different counties, by Messrs. Mudge and Dalby. *Plate VIII. fig. 1. of Surveying*, shews the perspective view of this masterpiece of workmanship, nearly as represented in general Roy's third plate; but his account, having reference to the several plates, will not answer our purpose. The stand on which the instrument is placed for use, is a four-legged mahogany stool A B C, braced as seen in the figure, with an octagonal top perforated at the centre by a hole of nine inches diameter. This stool or stand, when used, has its feet screwed fast to the tops of four piles driven into the ground, and nicely levelled, before the instrument is placed

THEODOLITE.

placed on it, and one of the four fastening screws may be seen at B, at the junction of the bracing bars. Upon this stood another, but larger, octagonal board of mahogany, D E, rests, which has a ring or circular curb on its plane, about half an inch from the sides of the octagon: this upper octagonal board may be fixed to, or released from, the top of the stand by four vertical screws, which penetrate both boards, but which allow one to slide over the other, so as to be either concentric or excentric, as the adjustment of a plumb-line to the mark or hole under the instrument may require, for the exact place of the station, over which the centre of the instrument must be exactly fixed. The four horizontal screws of adjustment, of which three are seen at F, F, and F, carried by the board D E, are so contrived as to effect this adjustment by pressure against the edge of the stand, after which the two octagonal boards are made fast together by the said four vertical screws not shewn. The upper octagonal D E has an open conical socket of brass, three inches in diameter, in its centre. Next above the board D E, thus adjusted and secured, comes the third board, which is circular, and which forms the basis of the instrument. In the centre of this base another brass conical socket, three inches and a quarter in diameter, is made fast, and slips over the smaller conical socket of the board D E of adjustment for central position, so that the centre of the instrument being concentric with this board partakes of the adjustment, while the plumb-line descends through both sockets down towards the ground. The large mahogany circle G H, of more than three feet in diameter, is supported by several pillars connected with the circular board, which we have called the base of the instrument, and forms with them a balustrade, that protects the instrument, as seen in the figure. A brass circle of three feet diameter, within the balustrade, is attached by ten strong conical radii to the large vertical hollow axis, formed into the frustum of a cone, of twenty-four inches in height above the metallic wheel, which we shall in future denominate the graduated circle, when considered with its radii and hollow axis attached to it. This axis, by way of distinction, may be called the *exterior* axis; it has a collar of cast-steel driven fast into the cavity of its inferior or thicker end, and a plate of bell-metal, with a sloping edge, surmounts the superior end, which plate may be raised or lowered by means of five screws acting vertically. The instrument stands on three short feet near D and E, and at an equidistant point not seen behind, which feet are firmly united together, at the place where they branch off, by a circular strong plate of bell-metal, upon which is carried an attached vertical cone of metal smaller than the former one, and as it fills the cavity of the other, we will call it the *interior* conical axis; the exterior one being moveable round the interior one without the least perceptible liberty, beyond what is necessary for rotatory motion. On the vertex of this interior axis is inserted a cast-steel pivot with sloping cheeks, which, entering the central hole of the bell-metal plate, exactly fits its cheeks there, while the bell-metal base of the interior axis fits the cast-steel collar inserted into the lower extremity of the exterior conical axis. This mode of centering allows the wheel to be taken off and put on without injury, and is also free from the objection that applies to those large instruments that have the superior end of the vertical axis supported in a frame that is liable to alter in its dimensions by exposure to the sun; of which imperfection, as we have noticed in our article CIRCLE, PIAZZI had great reason to complain. Besides, this kind of centre-work allows of carriage from one place to another, without any danger of injury being done to the instrument when properly packed. There are two achro-

matic telescopes with double object-glasses of each thirty-six inches focus, with eye-pieces of different powers both for erect and inverted positions. One of these telescopes lies across the body of the instrument, with the ends seen between the opposite pillars of the balustrade, the use of which is to watch the position of the instrument during the time of an observation being made; and, therefore, it requires but little elevation in altitude: the other is mounted, exactly like a transit-instrument, over the top of the exterior vertical axis, and has a semi-circle attached to the extreme end of its horizontal axis of motion, of six inches radius, and graduated for shewing angles of altitude or of depression. The Y's in which the pivots of the upper telescope move, are supported by the horizontal bar I K, which is braced by the ladder-pieces attached to the thick part of the exterior conical axis, and made fast to the top of this axis by its socket, as seen in the section in *fig. 4*; which section exhibits moreover the internal fittings of both the internal and external axes at their superior ends. This upper telescope has a spirit-level with the usual adjustments at the Y's, and at the bar of suspension for the horizontal position; and, as it will reverse in the Y's, and has moveable wires in the focus of the eye-piece, it may also be adjusted by a horizontal mark for collimation, and for taking exact altitudes, (as well as for taking minute angles of elevation without the semi-circle by the motion of the micrometrical wires,) when the level is applied to a rod on the *side* of the tube, as is the case in our drawing. When these adjustments are made, by dividing the errors between the proper screws, as usual, the level is hung to the cross-bar I K to watch its position while this telescope is used, and when both telescopes continue to bisect the same distant mark during an observation, with the bubble of the level in the middle, it is a proof that the instrument keeps its position. When a star or other object is viewed by night, the illuminating lamp K throws light into the axis of the telescope, which has a diagonal perforated reflector, as is usual in transit telescopes. A system of darkening prisms is also applied to the same end of the axis to regulate the quantity of light that shall come to the eye. All these adjustments and appendages have been minutely explained under our articles CIRCLE and TRANSIT-Instrument, and therefore need not be detailed in this article; but it may be proper to observe, that the semi-circle has a moveable clamping-piece, bearing the steel arbor of a vertical screw, the lower end of which falls on a polished piece of steel on the plane of the horizontal bar I K, the use of which clamp and screw is not only to give a slow motion in altitude, but to allow the preponderating eye-end of the telescope to rest steady thereon, while the observation has been read and repeated. The observation in altitude is read by the compound microscope at I, which is nine inches long, and which, by means of its micrometrical screw, reads the divisions of the semi-circle to the accuracy of 5", when an allowance of 12" is made for excentricity.

When this theodolite was first brought into use, it was found that the screw L, with an ivory thumb-piece, moved the circle in azimuth by jerks, on which account the apparatus for slow motion, seen in *fig. 2*, was substituted, in which two crown-wheels and a Hooke's joint are introduced to give motion to the tangent-screw; which addition not only remedied the jerks, but allowed the observer to reach the handle while his eye remained at the upper telescope. The large brass horizontal circle is divided into quarters of a degree, and the subdivisions are made by the vertical micrometrical microscopes, the divided heads of which read exact seconds, when properly adjusted for zero,
for

THEODOLITE.

for distinct vision, and for power. The screw of the vertical micrometers has seventy-two threads in the inch, and the notches that indicate the fifteen minutes on the micrometrical scale of steel, are formed by this screw, which we mention particularly, because this mode of reading was probably an original mode, though now become common. These vertical microscopes, G and H, have each a stage, represented by *Plate IX. fig. 4*; and a dot made on a thin slip of gold, called a *gold tongue*, lies under the object-lens in such a situation, that the capstan screws can adjust it to a given place in the field of view of each microscope, so as to become a *mark* for making the adjustments by, and for bisecting the circle at reversed opposite readings. The position of the three glasses of each microscope is seen in *fig. 3.* of the same plate, together with the magnified appearance of the notched scale and divisions of the circle. In *fig. 5.* the general plan of the micrometer is exhibited, and in *fig. 6.* is the plan of the stage where the pillars enter, that support the microscope. *Fig. 7.* shews the lower or steel slide, and *fig. 8.* the upper or brass slide, that separate the wires of the micrometer; while *fig. 9.* is a representation of the long horizontal microscope that reads the divisions of the semi-circle above noticed, at the letter I in the large figure of *Plate VIII.* As it was not easy to describe the construction of the three feet, two of which, we have said, only are visible, opposite to D and E, we have added *figs. 3. and 5.* in *Plate VIII.* to illustrate their position. In *fig. 3.* the piece F F, as before, is a portion of the stand, and D E a portion of the octagonal board, to which the screw F is attached, that presses against the angular corner of the stand, into which a piece of brass is let for the screw to press against, an end section of which is shewn in *fig. 5.* with the same letters of reference to the same parts: M N is a section of the base of the instrument, and O one of the three brass branches that bears the foot-screw P, and its two side screws or tightening screws Q, R, as seen in *fig. 5.* At S is a curved piece of box, fast to M N, which bears the principal part of the weight laid on this screw, and does not gall the parts on which it slides, when a circular motion is given; but, to take off a part of the weight, a cylindrical roller near S is put to a horizontal spring bearing the central pin of the roller, which spring presses the roller even with the face of the curved block of box, and may be made to take more or less of the weight by a screw pressing upon it from above, and giving it more or less tension. Hence all the parts of this large instrument are strong, and yet the moving parts are made to go freely and smoothly; and the only alteration that can apparently be made for the better, is the addition of a third vertical microscope, for which the construction is peculiarly adapted; for each branch of the triple bar that carries the three feet, being braced firmly, is made as though each was intended to have a microscope over it, which is the case with only one; and an additional foundation for the second stage is made to receive the second microscope, as we think, unnecessarily; for if three equidistant microscopes had been used instead of two opposite ones, not only would the errors of division and of eccentricity have been lessened thereby, but in the reversed position new parts of the circle would have been pointed to, equidistant from the former three, so that six portions of the circle would thus have been employed in measuring a reversed observation, which the present astronomer royal first pointed out to be an advantage peculiar to three readings on a horizontal circle. We have been informed, that it is yet intended to have three microscopes attached to the horizontal circle of this large instrument, to be used as we have here suggested. For the

advantage of a triple reading, see our table for three verniers in the article CIRCLE.

After having given a description of Ramsden's great theodolite, we proceed, in the next place, to explain how its different adjustments are made, for putting it into a state proper for use, which we cannot do better, than by adopting the directions laid down by general Roy himself.

The Adjustment of the Axis Level.—The axis of the upper or transit telescope, being brought over any one of the feet, and the circle being clamped, hang the axis level on the pivots, or axle of the telescope, and bring the bubble to the two indices; then reverse the level, that is, turn it end for end, and note the difference. Bisect this difference, one half by the level's adjusting screw, and the other half by that foot-screw only which is in a line with the axis. This operation being repeated until the difference wholly vanishes, the level will be truly adjusted, that is to say, the bubble will rest between the same points in both positions.

Adjustment of the Elevation Level.—This level being suspended on the rod attached to the outside of the transit telescope, screw the erect eye-tube on, to make that end preponderate. Adjust the bubble to the indices by the steel finger-screw at the tail of the semi-circle's clamp, reverse the level, and note the difference. Then bisect that difference, and correct one half by the finger-screw, and the other half by the proper adjusting screw under the level, and so on, repeatedly, until the difference wholly vanishes. The level may then be hung on the two pins that project from the horizontal bar which carries the telescope, where, being parallel to the axis level, it will shew, when that is removed (as is commonly the case when terrestrial objects only are observed) whether the plane of the instrument suffers any alteration. If this should have happened, the level on the horizontal bar is at all times sufficient to correct it.

To set the vertical Axis perpendicular.—This may be done by either level, but best with the axis level, which, being suspended on its pivots, must be brought parallel with two of the feet of the instrument; and by the screws of these two feet, the bubble is to be brought between its indices. The circle being then turned round 180° , if the bubble changes its place, half the difference is to be corrected by one of the feet-screws, and the other half by two capstan-headed screws, that act against each other, under and belonging to one of the Y's, or supports, in which the pivots rest. When the bubble is found to be just in these two positions, turn the circle 90° , which will necessarily bring the axis over the third foot of this instrument: then correct any error there may be by that foot-screw. In this manner the circle will be made to revolve again and again, without any alteration whatever of the bubble, which shews that the vertical axis is then truly perpendicular to the horizon.

To make the Line of Collimation in the Telescope at right angles with the transverse Axis.—The pivots resting in their Y's, direct the telescope to some distant well-defined object, and let the circle be clamped. Then reverse the axis, that is, turn the telescope upside down. If the intersection of the wires does not coincide with the object in both positions, half the difference must be corrected by the motion of the circle with the Hooke's joint, and the other half by the motion of the brass slide in the eye-end of the telescope, by applying the milled-head key in the small socket seen in the figure; and so repeatedly until the difference wholly disappears.

To set the Rod on which the Elevation Level hangs parallel to the Line of Collimation.—The vertical axis being supposed to be

THEODOLITE.

be nearly vertical, hang the level on its rod, and rectify the bubble by the finger-screw of the clamp. Set the horizontal wire on the steel slide, to intersect the centre of the oblique wires, and place the dart or index at zero on the micrometer head. Then observe some distant distinct object covered by the horizontal wire. Invert the semi-circle, that is, turn the azimuth circle 180° , and the telescope upside down, so as to bring the wire upon, or nearly upon, the same object. Now, if the level be not right, rectify it by the finger-screw at the tail of the clamp. If the telescope does not now accurately cover the same object, as in the former position, bisect the difference by the finger-screw of the clamp, and then rectify the bubble by the capstan-nuts under one end of the rod. Repeat this operation until the level is right, when the telescope sees the same object in both positions, and thereby the rod will be brought parallel in altitude to the line of collimation, or axis of vision.

We have described other and more recent constructions of large circular instruments, under the word **CIRCLE**, that have all the properties of the theodolite which we have here described, and some of which have the advantage of a large vertical circle, that renders their use in astronomy co-extensive with their application to geodetical operations; and which therefore we recommend in preference to the bulky instrument with which the English trigonometrical surveys were performed.

A theodolite of a portable size, and of Troughton's best construction, is exhibited in *Plate IX. fig. 1. of Surveying*, such as is adapted for land-surveying, or for the surveying of harbours. A, B, C, are the three mahogany legs of a tripod, surmounted with brass joints which allow the legs to form one entire cylinder, about four feet long. The brass-work above the three joints has a male screw, upon which a socket, under the brass circular plate D E, screws, and bears the instrument, which is almost entirely of brass. This plate D E has four sockets made fast into it, projecting both above and below, as seen in the figure, in which are exhibited three out of the four, with as many screws with milled heads, that ascend and descend as they are turned round, forwards or backwards, by means of their connection with their respective sockets, that have each a female screw: the heads of those screws press against the inferior face of the upper circular brass plate F G, to which a ball, ending with a vertical axis, is attached, and is embraced by the upper portion of the socket of plate D E, within the four screws. The intention of the ball and socket, and of the two plates with the four intervening screws, is to place the axis of the ball in a vertical position, and to keep it in that position while the parts above are employed in making an observation; which office this mechanism will perform on sloping as well on level ground. The axis of the ball, however, is made hollow, to admit of a smaller solid axis within it, and has also two sockets or tubes surrounding it; all which have separate motions, when the ball is made fast by the pressure of the four screws. The inner tube is attached to the graduated circle L M, of eight inches diameter, the chamfered edge of which circle is solid silver, that receives the dividing strokes read by the microscope K: and the clamping piece, seen separately in *fig. 2*, will fix the said tube and graduated plate in any given situation by means of the screw F, after which the screw G with the milled head, attached to the plate F G, will produce the slow motion when necessary. The lower telescope H I turns on two pivots not seen, one of which pivots has its hole in a cock, borne by a smaller circular plate under the graduated plate, into which the two screws H and I

enter, and the other pivot enters the outermost tube; so that an elevation or depression of about 20° can be effected by this telescope, before its motion is limited by the superior and inferior plates. This telescope has a proper motion in azimuth, independently of the graduated plate, which motion is produced by the thumb-screw H, the axis of which has a pinion acting with a concealed wheel made fast to the graduated plate; but when the clamping-screw I is made fast, then the telescope and graduated plate have but one common motion, which is commanded by the tangent-screw G of the clamping-piece F G. The use of the separate motion of this telescope will be explained presently. Above the graduated plate L M, and in close contact with it, the vernier-plate revolves with the solid or innermost axis, that is fast to it, and its clamp and screw of slow motion are hid from the sight by the superincumbent frame. This plate, which has four opposite verniers, each reading to the accuracy of $15''$, will move separately, or may be clamped to the graduated plate, as occasion may require. Upon the plane of this vernier-plate, two spirit-levels are placed with their proper adjusting-screws, one of which is seen at N; but the other, which stands at right angles to this, is concealed in the drawing by the frame-work. A compass and magnetic needle are also concealed within the frame, but may be conceived to be concentric with the vernier-plate within the said frame. The tail-piece of the revolving microscope K fits into a circular groove under the graduated plate L M, and, without having a centre of motion, will slide along the groove into any of the four positions, where the verniers require to be read, without interfering with any of the other motions. The instrument now before us has been some years in use, and is drawn on an enlarged scale, that all the parts may be the better described; but the most recent theodolites of this construction have only three verniers, in preference to four, by reason of the property, which this number has, of measuring at six different and equidistant points on the graduated limb, when the measurement of an angle is repeated in a reversed position of the superior telescope; so that whatever errors of excentricity or of graduation may exist in the horizontal circle, they will be made to vanish, in a great measure, by their counteraction in the reversed position of the verniers. Upon the plane of the vernier-plate is screwed, by three screws, forming an isosceles triangle, the frame which supports the pivots of the horizontal axis of the semi-circle P Q, on which the upper telescope T U is placed. The arm, which bears the microscope O for reading the altitude or depression measured by the semi-circle, has a tube that slides upon the projecting horizontal axis, that allows of some degrees of motion between the end-bars of the frame; and another arm, that clamps the opposite end of the said axis, has a tangent-screw of slow motion at R, which finishes the final contact of the intersecting point of the spider's lines, within the eye-end of the telescope, with the object viewed. The vernier for the semi-circle is screwed to the frame, after spanning over the compass-box; and its exact place may be adjusted by the screw of the frame above M, which stands at the apex of the isosceles triangle formed by the three screws. The level, that is seen under and parallel to the upper telescope, is attached to it by two pairs of screws, one pair of which adjusts for the elevation or depression of one end of the tube that holds the bubble, and the other pair adjusts laterally for true parallelism in this respect: when the pins T and U are removed, the upper semi-circle of each ring, V and W, will turn back each on a hinge, and allow the telescope to be taken out of its Y's, for the purpose of being reversed in position;

THEODOLITE.

position; and in both situations the telescope is capable of having a circular motion, that carries the attached level round with it an entire revolution. During this revolution, an eye observing the intersected point of the field of view, as projected on a distant point, will see whether or not any adjustment of the spider's lines is necessary, and in what respect. The aperture of each telescope is an inch and a half, and the ordinary magnifying powers are from ten to eleven, with nearly fourteen inches of tube; but the upper or measuring telescope has a second eye-piece of the positive kind, which produces a magnifying power of twenty times. There are three spider's lines in each eye-piece, one horizontal, and two crossing it so as to include a small angle between them; which method of fixing the lines, allows the observer an opportunity of bisecting the said small angle by a vertical staff erected at a distance, which is better than covering the staff with a vertical line, that would disappear upon the plane of such staff. Before we proceed to explain how this theodolite is used in the field, it will be requisite to shew how the previous adjustments are to be performed.

When the instrument is screwed to the head of the tripod, the legs must be opened wide enough to ensure a firm position, and the points must be pressed into the ground equally, exactly over the hole into which a station staff has been, or is intended to be, inserted; so that the plumb, suspended from a pin at the junction of the legs, will fall exactly upon the said hole; in which situation the *station*, marked \odot , is said to be taken.

When the theodolite has been properly fixed in its station, the first adjustment that will require to be made, is that which regards the *line of collimation*. When all the parts of the instrument are properly in their places, let the upper telescope be pointed in a horizontal line, that passes over two of the four screws of plate D E, and note what point in a distant object is covered by the horizontal spider's line, near the middle of the field of view; then turn the telescope half round in the Y's, till the level lies above it, and observe if the same point is again cut by the said line; if not, elevate or lower the horizontal line by the proper screws in the eye-piece, releasing one and screwing up the other, till the distance between the two points, corresponding to the two positions, is bisected by the horizontal spider's line: and if, when the telescope is turned back to its original position, with the level under it, the spider's line covers the point adjusted to, the line of collimation in altitude or depression will be correct; but if not, the operation must be repeated delicately, till the horizontal line covers the same distant point in both positions. The same operation will also put the vertical line correct, or rather the point of intersection, when there are two oblique lines instead of a vertical line, as in Troughton's theodolite; and the adjustments will be known to be complete, when the point of intersection continues on the same distant point, while the telescope is made to revolve round the line of collimation as an axis.

The second adjustment is that which puts the long level parallel to the rectified line of collimation. While the telescope remains parallel to the line that joins two opposite screws of plate D E, adjust those two screws by turning them in opposite directions, until the bubble is observed to be in the middle of its tube under the telescope: then, the semi-rings V and W being previously turned back, reverse the ends of the telescope, and also of the level attached to it; and if the bubble will resume its former situation in the middle of the tube, both the line of collimation and the level will be truly horizontal, and consequently parallel to each other; but if the bubble recedes to one end, bring it back one half by the screws that elevate or depress one end of the level, and the

other half by the screws of plate D E. Let this operation be repeated till the bubble will remain in the middle of the tube, after the telescope has been reversed into both positions. The adjustment of the level, however, is not yet complete; for though the axes of the two tubes may be equidistant at both ends of the level, yet may they be inclined so as to form an horizontal angle with each other at some distance; and in this case the bubble will run to the higher end of its tube, when the telescope rotates; there are therefore two lateral screws, which adjust the parallelism of the two tubes, so that the bubble will remain in the middle, in every part of a rotation of the telescope round its line of collimation, which adjustment must now be made; and if this lateral adjustment should be found to derange the vertical one before made, it must be re-adjusted, and the level will then be in a proper state for use, provided the Y's are alike, and also the cylinders that rest in them; but if not, the bubble will not rest in the middle in both of the reversed positions, till they are made so.

The third adjustment that we propose to explain, is that which puts the line of collimation exactly at right angles to the axis of the semi-circle's vertical motion, which has not yet been described, but which is essentially necessary to be attended to, more particularly by the maker. Let the upper telescope be directed to some horizontal well-defined mark, that is included within the angular space formed by the two oblique lines, just where the vertical line would have been, if such line had been used, while zero of the vernier coincides with zero (360°) of the horizontal limb of plate L M; then all the screws being fast, except the one which allows the vernier-plate to revolve, turn 180° in azimuth, and reverse the telescope by taking it out of its Y's, into its original position with respect to the mark; and if this is seen in precisely the same situation in the angular space, (though not perhaps with respect to altitude, if the axis of the vernier-plate was not previously adjusted,) the line of collimation will be at right angles to the axis of the vertical motion; but should this not prove to be the case, one of the Y's will require to be altered laterally, but the adjustment of the level will not be deranged thereby. This alteration of one of the Y's had, however, better be effected by a regular workman, and should never be neglected by the maker.

The fourth adjustment, which might have preceded the third without inconvenience, is that which makes the common axis of motion of the vernier-plate and horizontal graduated circle truly vertical. This is done partly by the screws that fix the ball and socket, inserted into plate D E, and partly by the adjusting-screw R of the vertical semi-circle. Hitherto the upper telescope has lain over two of the four screws only, and in a horizontal line, with the bubble in the middle. Let it now be turned along with the vernier-plate just 90° , till it lies over the other pair of opposite screws, and see if the bubble be now also in the middle, if not, make it so by those screws; and if, after this operation, the bubble will remain in the middle during a whole revolution of the vernier-plate, in both the reversed positions of the telescope, the vertical axis of motion will be truly adjusted.

The fifth adjustment relates to the levels fixed to the plane of the horizontal graduated circle, which are useful in watching the horizontal position of the instrument, while an observation is making; these, which are at right angles to each other horizontally, must also be separately at right angles to the vertical axis that carries them round. When this axis has been adjusted, as we have just explained, by the level of the upper telescope, the bubbles of both

THEODOLITE.

the fixed levels must be brought to the middle of their respective tubes by their proper screws, so that the bubbles of all the three levels may remain stationary in every part of the revolution of the vernier-plate, which they will do if its axis is truly vertical.

The sixth adjustment is that which puts the axis of the semi-circle's motion truly horizontal, or at right angles to the vertical axis of the horizontal circles: this is known to be so, when the point of intersection of the spider's lines will cover a long plumb-line, suspended at a distance, as the angle of elevation increases, from the inferior to the superior end of the suspended line; and still better by trying if the pole star, and its reflected image, seen in a basin of quick-silver, will be successively covered by the said point of intersection of the spider's lines. In some theodolites, the horizontal axis lies in adjustable Y's, like those of a transit-instrument; but in the instrument before us, the adjustment was made permanent by the maker.

Lastly, the adjustment of the vernier to zero of the semi-circle is made by the screw near M, which elevates or depresses the whole frame in which the telescope and semi-circle move, and consequently alters the situation of the level, which has its bubble brought back again by the screw R, that gives slow motion to the semi-circle, when the clamp at the superior end of the arm is made fast to the axis of motion; but it is not essential that zero of the vernier should be at zero of the semi-circle when the level is right, because when an altitude or depression is repeated in the reversed positions of the telescope, the two readings will have equal and opposite errors; and one half of the difference of those readings will be the constant index error, which may be ascertained with great precision from an average of a number of reversed observations.

The lower telescope, being placed as a guard to watch any azimuthal alteration in the position of the instrument, requires no adjustments, except that for distinct vision, after it is brought to its object by its proper vertical and horizontal motions, in which situation its horizontal motion is clamped by the screw I under the horizontal plate.

After the adjustments are all made, or examined, the theodolite may be used for measuring either horizontal or vertical angles in the following manner. Let us suppose two staves erected vertically on level ground, one towards the east and the other towards the south of the station where the instrument stands in a state of adjustment; and let it be required to ascertain the angle subtended at the centre of the instrument by a line joining these staves: in the first place, the lozenge of the vernier No. 1. must be clamped to 360° on the horizontal circle, and the clamping screw F must be released, so that the upper telescope, vernier-plate, and graduated horizontal circle, may all move in azimuth together, till the staff to the east is seen in the field of view; this clamp F may then also be made fast, and the screw of slow motion, G, will bring the staff to bisect the angle formed by the spider's lines, in which situation zero of the measuring circle is truly placed: in the next place, bring the lower telescope, by its proper screw H, into precisely the same situation, and fix it there by the fixing screw I: then, having examined that the upper telescope has not moved from the staff by any accident, release the clamping screw that held the vernier-plate, and turn the upper telescope, till the second staff in the south bisects the angle of the spider's hairs; which may first be done roughly before clamping, and afterwards more exactly, by the tangent-screw of the clamp; then, having examined the position of the lower telescope again, let all the four (or three) readings of the vernier-plate be put down, and take the fourth (or third) part of their amount as the true angle, and see that

both telescopes have their staves bisecting their respective angular spaces as at first, after the measures are read, and then the average thus ascertained will be nearly the true angle: but to prove the exactness of the measure thus taken, and also the accurate construction of the instrument, the telescope resting in the Y's may now have its position reversed, and then No. 3. of the four verniers must be clamped to the point 360° of the graduated circle, and the same operation must be repeated, when another average of four measures will be had, and an average of these two results with opposite index errors, may be considered as very near the truth; and more particularly if there are only three verniers; for then, as we have stated above, the readings will be at six equidistant points of the circle, and will correct for eccentricity as well as inequality of divisions, if any exist. In ordinary measurements of angles, in small surveys of land, this attention to extreme accuracy may be superfluous, where the instrument is well centered and graduated: but where the lines to be measured are long, the angles cannot be taken with too much care; particularly when any side of a triangle is to be determined, or checked, by the opposite angle.

In taking an angle of altitude or of depression with the semi-circle of the theodolite in question, very great accuracy is not to be expected, seeing there is but one vernier; but by proper attention to the previous adjustment of the level of the upper telescope, and by using the telescope in the reversed positions, two measures will be obtained with opposite errors, that counteract each other's effects, so as to render the measure true to 15". It is hardly necessary to add, that the measure of a vertical angle is taken by the horizontal spider's line, and that the lower telescope is of no use in taking such measure.

We proceed, lastly, to exemplify the use of a common theodolite by an actual survey of a small estate, such as will come within the limits of one of our plates, and by an explanation of the manner in which a *field-book* is kept in practice, and its contents transferred to the formation of a map, agreeably to the most approved methods of measuring and plotting an estate of any assigned dimensions. For this part of our article we are indebted to Mr. James Wadmore, whose experience and acknowledged skill, in his profession of land-surveyor, eminently qualify him for communicating the requisite information which we have referred for this place, to render the subject of *surveying* complete.

"Preparatory to making a survey with the assistance of a theodolite, I consider it indispensably necessary, (says Mr. Wadmore,) that the surveyor should feel well assured that his instrument is in a perfect state of adjustment, and also that his chain is correct, otherwise no dependance can be placed upon the most particular and minute field-book he could make; for if these primary things are not attended to, the result of his labours, on plotting his dimensions, will turn out to be only so much time lost, as well as that which he may have bestowed upon his survey.

"In order to obviate these difficulties in some measure, I most earnestly recommend to the young practitioner, that, in choosing his theodolite, as well as his protractor, case of instruments, plotting scales, &c. on which every thing depends, to enable him to complete his surveys with correctness, that he be not sparing of a little money in purchasing those that are good, and can be relied upon for accuracy; as the being furnished with such, in the first instance, will be the means of ensuring to him that ultimate dispatch in the progress of his profession, which will lead him to the most satisfactory results.

"As nearly the whole of the profession of surveyors have some material or nice distinctions in keeping their field-

THEODOLITE.

books, arising either from the peculiar methods they have been taught, the instruments they use, the methods the more experienced have been led to adopt; from the more enlarged and enlightened views they may have taken to ascertain the best possible manner of facilitating the desired object, that of making a correct survey; or from the more improved state of mathematical science; I trust I may be permitted to offer the following method of taking dimensions, the form of keeping a field-book, and the method to be adopted in plotting the same. Having made use of the theodolite, and endeavoured, by practical experience, to avail myself of its most beneficial services, I have no doubt but the specimen I now submit will be most readily comprehended, and the most intricate and difficult surveys accomplished by the same means; *viz.* with the assistance of the theodolite, where other methods, by possibility, may be found partially (if not wholly) to fail.

“On commencing a survey, I have always found it necessary to look out for an intelligent labourer, well acquainted with the locality of the neighbourhood, with whose assistance, and another to carry the theodolite, I usually commence; invariably taking the chain myself after the leader: and here it may not be amiss to remind the young practitioner, that, in following, he must be most particular in directing his chain-leader in a straight line, otherwise the relative bearings of the stations forward, taken by the theodolite, will be rendered incorrect, and the protractor in plotting will not fail to convince him of his error, to his great chagrin and disappointment. I must also remind him of the necessity of keeping his chain-hand, and also directing that of his chain-leader to be kept as near the surface as conveniently can be done, and the chain properly stretched, by which means he will obtain more correct lengths in measuring from station to station, insuring thereby the greater accuracy in his survey (particularly if it be large); as he will very early find, in the course of his practice, that errors, when once begun, will rapidly increase; to prevent which, it will be found very convenient to plot every day's work on his return home, before he commences another, when, if any error is found, it can be rectified on the following day.

“Many other necessary cautions might be given to the young surveyor, which by some may be thought superfluous, but the following I cannot help recommending to his attention; *viz.* that of being exceedingly particular in marking and describing his exterior boundaries, having myself, more than once, seen litigation prevented by the production of correct surveys, where the boundaries of estates in dispute were clearly defined. And let him not be fearful of taking too many offsets, or dimensions; for by trusting observations necessary to his survey to memory, he cannot but fail to omit some; whereas by a copious field-book, not even the slightest bend in a fence, or object of any sort, can possibly be omitted. Above all, let him feel well satisfied of the correctness of his chain; to enable him to do which, he should always have a spare one, on a large survey, to correct by; as it is well known that accidents will happen by the breaking of the same, by loss of rings, &c.; and the offset staff, from being too short, cannot be depended upon for this purpose.

“Having said thus much, I now proceed to shew the method I have practised in surveying with the theodolite; in doing which, I shall first premise that I have always considered it advantageous to take a view of the estate to be surveyed, by doing which, I have been enabled to avail myself of studying the best stations, and to judge how the business may be accomplished with the greatest facility.

“The theodolite which I have been accustomed to use

is a very good one, made by Cary, about five inches diameter on the limb, which is finely graduated, with a vernier reading minutes, and with degrees numbered from 1 to 360; it has an achromatic telescope and vertical arc, for the purpose of ascertaining the angles of elevation and depression in hilly surveys, on one side, and the corresponding deductions to be made in the chain lines on the other, and moves by rack-work.

“The method adopted by me, after some years' practice, in keeping a field-book, perhaps may be thought singular, namely, that of commencing at the bottom of the last page of the same, and working upwards therefrom; but it will readily be seen, on reference to the accompanying field-book in Plate X. to be the best way, as in proceeding, you meet the objects you have to describe in succession as you advance, and it affords a much greater facility in laying off the offsets from the chain-lines, than in the other way.

“It is well known that the needle is frequently affected, in the first place, by the atmosphere, and liable to get out of order; in the second, the chain being made of iron as well as the arrows, and their not being moved a sufficient distance in general, when the theodolite is planted for taking an angle, it may thereby be very materially affected; in the third, articles of iron or steel may be about the persons attending the survey, which may have the same effect; in the fourth, it may not be found improbable, from the very nature of the ground on which a survey may be carried on, that veins of iron, or metallic ore, may exist under the surface, which will not fail to influence the polarity, to the utter detriment of ascertaining the true bearings; and, lastly, without a vernier, the angle cannot be read with sufficient accuracy.

“Trusting that the foregoing remarks will suffice to convince those, who may be carrying on surveys by the needle alone, of the danger of trusting to this method, as well as to prevent the student in the profession from so doing, I now proceed to shew, that by taking the included angles of the survey upon the limb of the theodolite, and by carefully noting them in the field sketch, (as seen in the plate,) no such danger can possibly exist. The following problem will give sufficient proof of the accuracy of this method of measuring the internal angles of any geometrical figure, whatever may be the number of its sides; *viz.* double the number of sides, and multiply them by 90°; and then, if 360° be subtracted from the product, the remainder will be the sum of all the internal angles; for if we suppose lines drawn from every angle to one common point in or near the middle of the figure, there will be as many triangles as there are sides, and the sum of all the angles at the apex, or point assumed, will be 360°, as will appear when circumscribed by a small circle: therefore, as every triangle contains 180°, the amount of all the triangles will be as many times 180° (or 90° × 2) as there are sides, when diminished by 360°. In our example, the survey is bounded by five chain lines, with as many included angles, and therefore the amount of the angles will be $5 \times 90^\circ \times 2 - 360^\circ$; or $900^\circ - 360^\circ = 540^\circ$, agreeably to the subjoined measurements taken in the field; *viz.*

Having

THEODOLITE.

“ Having said so much relative to the means of applying the theodolite most beneficially, I shall now explain an example of each of the methods I have alluded to; in doing which, I beg it may be understood, that although the difficulties I have enumerated may in some cases exist, yet it is possible a survey of moderate extent may be carried on by the needle with caution sufficient to obviate them; though I am fully satisfied, from experience, that the latter method is the most to be relied upon; I shall, however, proceed to exemplify both in the order before-mentioned.

“ *The Method of using the Theodolite in ascertaining the Bearings by the Needle.*—It will be seen by the field-book, that I commence at (station) $\odot 1$, at the back of the mansion: here, having the theodolite firmly fixed in the ground, by means of the four adjusting-screws, I set it perfectly level, first in the direction of the magnetic north, and afterwards at right angles: being thus satisfied, I set the vernier on the upper limb correctly to 360° on the graduated circle, and loosen the screw that fixes the instrument. I then move the graduated circle round until I ascertain that the needle points to N. in the compass-box, and then tighten the same screw, which prevents it from moving. Being now ready to take the bearing from $\odot 1$ to $\odot 2$, I direct the telescope to some object in that direction, keeping as near to the boundary-fence as can well be admitted, in order to reduce the length of the offsets; and having brought the cross-wires in the telescope to bear upon the object, I then look to see what part of the limb is cut by the vernier, which I find to be $330^\circ 2'$, and in a north-west direction. This I note down as in the field-book, and afterwards examine whether it is correct. I then direct the chain-man to move forward towards that object, leaving a mark behind, to return to, and proceed by first taking the following offset at 00; that is, at the place of commencement, I find an offset to the right of 86 links to lady Buckinghamshire's fence, and 40 from thence back to the building, which I note down. I then proceed, and at 212, I measure 5 links to the right, to a tree; and going forwards at 274, I measure 2 links to the left, to another tree, (which objects I am always induced to mark in the survey, for the purpose of embellishing the fair map): proceeding onwards at 310, the offset to the corner of lady Buckinghamshire's summer-house is 10; at 360, the chain touches the fence, consequently I mark the offset 0 (nothing); at 738, there is an offset to the left of 23 links, to a tree; and at 917, one to the fence of 13: continuing the line, I set up a mark at 950, and write the same down in the

field-book, thus “ (950) $\odot 3$ mark left,” meaning it for a station, to join to hereafter: I call it station $\odot 3$, being

the next number following the station I am measuring towards; and I inclose it in a circle, to make it more prominent to refer to; and mark the 950, the number of links on the chain-line, also in a circle, that I may not err in plotting off the situation of the same. I then go on, and at 960 come to the outer edge of a small clump of trees; at 975, an offset to the left ascertains the width of the clump that way to be 50 links, and one to the right of 13 links to the fence; 986 passes the outer edge of the clump; at 1031, an offset of 31 links on the left to the canal; at 1100, passing close to the edge of the canal, there being no offset on the left, I mark it 0 (nothing); at 1155, I cross the gravel-walk, the width of which was previously noted in the field-book to be 8 links; and at 1180, I halt, and mark the offset to the fence on the right 5 links. Here I again plant my theodolite, as before,

exactly over the station-hole; and after setting it perfectly level, and having brought the vernier 360° on the circle, and ascertained that the needle was correctly pointing to N. in the compass-box, I tighten the fixing screw, then move the telescope round gently to the left, until the cross-wires cut a conspicuous object in the direction in which I mean to proceed, and ascertain that the vernier cuts $235^\circ 7'$ in a fourth-west direction in the box. This I note down immediately in the field-book, as there represented; and after examining that I had done so correctly, I proceed on to measure the line from $\odot 2$ to $\odot 4$, taking the offsets right and left, and making the necessary remarks, to enable me to give a correct map and description of the estate, and so on throughout the survey. I have been particular in the field-book, which I trust, by the above description, will be considered to be a plain and facile way.

“ *The Method of using the Theodolite in ascertaining the Angles upon the graduated Circle, without Reference to the Needle.*—On commencing, I plant the theodolite firmly in the ground, and after adjusting the level perfectly, and setting the vernier to 360° on the limb, I move the circle round, until I ascertain that the needle in the compass-box points correctly to N.; then tightening the screw that fixes the instrument, as before, I move the telescope gently round in the direction of the line to $\odot 2$, in doing which, I find that the vernier cuts upon $330^\circ 2'$ N.W. This is noted down, in order to shew the bearing of the estate upon the map, and which, on being deducted from 360° , leaves an angle to the left of the meridian of $29^\circ 58'$, as shewn in the example: then leaving a mark at station $\odot 1$, and having proceeded along the line to station $\odot 2$, and taken the offsets, and made the necessary remarks in the field-book, as in the former method, on arriving at $\odot 2$, I again plant the theodolite firmly in the ground, and adjusting it as before, move the telescope round until the cross-wires cut the lower part of the mark left at $\odot 1$: then noting in my field sketch the number of degrees cut by the vernier upon the limb, without regarding zero, I afterwards move the telescope carefully round to the right, and direct it towards $\odot 4$; and bringing the cross-wires in the telescope to cut the object proposed to be measured to, I look and see the number of degrees cut by the vernier on the limb, as before: deducting one from the other, I get the \angle at $\odot 2$, viz. $85^\circ 14'$; and after having measured the line, on my arriving at $\odot 4$, I proceed exactly in a similar way, by first looking back to the last station, and then forward to the next, deducting the number of degrees and minutes in one direction from those read in the other, which gives the angle $88^\circ 18'$. Following this course, I proceed on the survey until all the angles and sides are completed.

“ It is necessary, however, before quitting each station, to take particular care in reading off the angles by the vernier, and also in writing them down correctly: and in this way of proceeding, the trouble, of adjusting for zero of the vernier to 360° at every station is avoided.

“ By plotting, is understood the making of a draught of the estate from the field-book; and as the instruments necessary to be used by the surveyor, in taking the dimensions in the field, are such, that he may be enabled to ascertain distances and angles correctly; it naturally occurs that corresponding requisites are necessary to make a ground-plot, or draught thereof, for laying down the quantities of the several angles, and of the distances measured by the chain upon paper, which are usually accomplished by means of the protractor for the former, and scales of equal parts for the latter.

“ With respect to the protractor, I have hitherto used, and recommended the young surveyor to use, one of eight inches

inches diameter, graduated to half a degree; and numbered from 1 to 360°, to correspond with my theodolite, with a vernier to mark off the angles to one minute of a degree, and a projecting pointer of two inches and a half beyond the outer radius of it, which in general surveying will be found, with care, to be sufficiently correct. This I had also from Mr. Cary of the Strand, together with the set of ivory plotting-scales, of about twelve inches long, decimally divided the whole length close by the edges, which are chamfered, to lay close to the paper, and give additional facility in pricking off the chain-lines, numbered 1, 2, 3, 4, &c. which are chains: these again are subdivided into tenths, every one of which divisions are reckoned 10 links. The numbers are so placed as to reckon backwards and forwards for convenience; but the method of using them is now so universally known, and so easily understood, as to preclude the necessity of any further description. I shall, therefore, proceed directly to state the method used by me of transferring the dimensions of the estate from the field-book, which is as follows; viz.

“ Having provided myself with a sheet of drawing-paper of sufficient size, I proceed to draw a line across the same in pencil, which line is nominally representative of the magnetic meridian, or that which the needle in the compass box points to. On a convenient situation on this line, with a fine pointer, I make a mark thus ⊙, and calling that (station) ⊙ 1, I lay the protractor with its centre upon the station-point, and take care that 360° of the protractor cuts the line on the northern side, and 180° the southern side of the meridional line: I then turn the moveable pointer to the left, until the centre of the vernier thereof cuts 330° 2' on the limb of the protractor, when I press down the pointer sufficiently hard to make a visible mark; then taking off the protractor, I draw a fine line with a pencil from ⊙ 1 to the point so pricked off; and afterwards, with a scale of chains, mark off the length of the first chain-line, viz. 1180 links: I also mark off 950 links for ⊙ 3, where a mark was left to join to. This done, I draw a line parallel to the first magnetic meridional line through ⊙ 2; when I put the protractor upon the same, taking care that the centre is exactly upon ⊙ 2, and that 360° and 180° exactly cut the meridional line north and south respectively; which being done, I move the pointer to the left; and when I find the vernier cuts 235° 7' on the limb, I again press down the pointer, and make a sufficient impression on the paper, to which I draw a line from ⊙ 2: then taking the scale, I prick off the length of the chain-line from ⊙ 2 to ⊙ 4, being 1274 links, and also 994 links on the same line from ⊙ 2 to a mark left there, and called in the field-book ⊙ 5. I proceed in this manner until the whole of the bearings and chain-lines are laid down, the last of which, or the connecting-line, viz. from ⊙ 10 to ⊙ 1, on being laid down, and the protractor having pricked off the angle 62° 41' N.E., I draw the pencil-line, and finding that it closes upon ⊙ 1, both as to bearing and distance, I am satisfied the whole is correct.

“ In laying down the angles and chain-lines of the survey taken by the latter method, without the use of the needle, little need be said; for, having first drawn the magnetic meridional line, marked N. S., a mark is made on some convenient part thereof for ⊙ 1; then laying the centre of the protractor thereon, and 360° and 180° thereof cutting the meridional line north and south respectively, I prick off 29° 58' on the left-hand, or north-west side, as being the relative bearing of ⊙ 2 from ⊙ 1; then drawing a fine line, I mark off the length of the chain-line, and lay the centre of the protractor upon ⊙ 2, and mark off the ∠ between ⊙ 1, which I first look back to, and ⊙ 4, the angle of

which, on deducting the quantity of one from that of the other, I find to be 85° 14': this I prick off, and drawing a line thereto, I mark off the length of the chain-line 1274 links, and so continue to proceed until the boundary is finished. I then proceed to mark off the offsets at their proper points in each chain-line, and connecting the points of such offsets, I have the boundary defined of its true shape and dimensions, as seen in the map. Lastly, I cast up the dimensions of the several triangles and offsets, considered as small trapezia, the method of doing which has been explained under the word CHAIN, and find the contents as expressed in the subjoined table.

THEODORE I. pope, in *Biography*, was the son of a bishop of the same name, and born at Jerusalem. He succeeded John IV. in the papal chair in the year 642. Of this pope no material circumstance occurs, except his controversy with the church at Constantinople, concerning the doctrine of the Monothelites; and this controversy is so little interesting to our readers, that we shall pass it over without any farther notice. Theodore died in the year 649. Besides some letters relating to the above-mentioned controversy, a memorial against Pyrrhus, the deposed patriarch of Constantinople, and his errors, addressed to the Eastern bishops, is preserved. Bower.

THEODORE II. pope, a native of Rome, succeeded Romanus about the close of the year 898. During his possession of the see, which he held only for twenty days, he caused the body of his predecessor Stephen to be taken out of the Tyber, and interred in the Vatican, and declared all his acts to be legal and valid. Bower.

THEODORE LASCARIS I. a Greek emperor, was son-in-law of Alexius Angelus, who imprisoned his brother Isaac and usurped the throne. Having valiantly but unsuccessfully defended Constantinople against the French and Venetians in the year 1204, he withdrew from the scene of contest across the Bosphorus, and put himself at the head of a body of troops; but when he found that the confederates were pursuing him, he sought refuge with the Turkish sultan of Iconium. Being joined by the inhabitants of Bithynia, he took possession of the country from the river Meander to the Euxine sea, and fixed his residence at Nice, where he was crowned by the patriarch of Constantinople. When his father-in-law heard of his success, he went over from Greece,

Greece, where he had remained concealed, to Asia, and implored the assistance of the sultan of Iconium in recovering that part of his dominions of which Theodore had taken possession; and having induced him to march with 20,000 men, he laid siege to Antioch on the Meander. Theodore, at the head of 2000 men, marched to its relief, and routed the besiegers. The sultan renewed the contest, and singling out Theodore, beat him off his horse; but the emperor recovering himself, unhorsed the sultan, cut off his head, and placing it on a pole, terrified his enemies, so that they all fled. Alexius was carried, as a prisoner, to Nice, where he was confined. Theodore, having made peace with the Turks, formed a treaty with the Latin emperor of Constantinople, and spent the remaining eighteen years of his reign, in securing his newly-founded empire, which he transmitted to his descendants; bequeathing it, at his death, to his son-in-law, John Ducas Vatases. The Nicæan empire terminated about fifty-seven years after its establishment by the elevation of its possessor, Michael Palæologus, to the throne of Constantinople. *Anc. Un. Hist. Gibbon. Gen. Biog.*

THEODORE, bishop of Mopsuestia in Cilicia, was priest, and probably native, of Antioch, a disciple of Diodorus, and an intimate friend of John Chrysostom. He was ordained bishop in 392 or 394, and died in 428 or 429. Sozomen says, that he was well skilled in the sacred scriptures, and in the liberal sciences of the rhetoricians and philosophers: and Theodoret calls him the doctor of the whole church, saying that he was bishop thirty-six years, and that he wrote against all heresies, particularly those of Arius, Eunomius, and Apollinarius. He wrote commentaries probably upon all the books of the Old and New Testament, though two or three of them are not particularly mentioned: and in these commentaries, as Photius says, he avoided all allegorical interpretations, and confined himself to the historical and literal sense. He defended this mode in a work concerning allegory and history against Origen. Some have charged him with treating the book of Job, the Canticles, and the Psalms, with disrespect; but these are the accusations of his enemies, and perhaps founded in error, as he actually wrote comments on some of these books. The book of Job he is said to have represented as written in a fabulous manner, though founded on truth; the Canticles he is said to have considered as a nuptial poem, and the Psalms as chiefly referring to the history of the times. His other works were numerous, and related to the controversies of his times, and to various theological doctrines. Most of Theodore's works are now lost, but some fragments of them may be found, chiefly in Latin, and perhaps not fairly represented, in the Acts of the second general council of Constantinople, or the fifth general council, held in 553, and also in Facundus, and in the Greek Chains. Fabricius assures us, that his commentary upon the Twelve Prophets is still extant in manuscript in the emperor's library at Vienna; and Montfaucon speaks of its being in the library of St. Mark at Venice, as well as in the library at Vienna, and in the Vatican.

Theodore was no less celebrated as a preacher, than as a commentator and general writer: under the former character he was admired at Antioch, at Constantinople, and all over the East. Distinguished by his learning and liberality, considering the time in which he lived, he has been charged with adopting the sentiments of Nestorius and Pelagius; and some moderns have called him the parent both of Pelagianism and Nestorianism; whilst others allow, that he held the Pelagian principle, but are of opinion that the charge of Nestorianism is not so clear. The above-mentioned council devoted a conference to the examination of Theodore's writings; and began with reading a creed attributed to him:

upon which the bishops clamoured for an anathema against his books and his person, and against all who did not join in that anathema. Several bishops, however, rose in his defence, and refused to concur in the anathema. Some learned moderns have charged him with adopting sentiments concerning the person of Christ similar to those of the present Unitarians; but of this fact there is no satisfactory evidence. *Mosheim. Lardner.*

THEODORE of Tarsus, a monk of that city, was ordained bishop by pope Vitalian, and being sent into England in the year 668; at the desire of king Egbert, was appointed to govern the church of Canterbury. In this high station he assiduously employed himself in settling the faith and ecclesiastical discipline of England; and after having spent twenty years in the performance of various important and useful services, he died in 690, at the age of eighty-eight years. With a view to the restoration of the neglected discipline of penance, he published a book of canons, under the title of "Penitential." In this book, sins were distributed into various classes, according to their respective nature and aggravation; and various kinds of penance were assigned to them; forms of consolation, exhortation, and absolution were prescribed, and other such matters respecting discipline were regulated. This Penitential passed from Britain to other countries, and became the model of similar works. It is still extant, in an imperfect state; and an edition of it was published at Paris by Petit, in 1679, 4to. with notes and dissertations. *Dupin. Mosheim.*

THEODORE STUDITA, an eminent ecclesiastic of the ninth century, was educated under Plato, head of the monastery upon mount Olympus, the government of which was committed to him in the year 795. By avowing his opposition to the marriage of Constantine Copronymus to one of the maids of honour of his wife, whom he had compelled for this purpose to take the religious vows, and by his separation from the communion of the patriarch of Constantinople, Theodore incurred banishment; but at the death of the emperor he returned, and was appointed abbot of the monastery of Studa, in the suburbs of Constantinople. On account of his disapprobation of the decision of a synod which declared the second marriage of Constantine lawful, he was banished a second time. After the death of the emperor Nicephorus, in 811, he returned from banishment, and was reconciled to the patriarch. For his zealous defence of image-worship in the reign of Leo, he was banished a third time, and treated by the emperor with great severity. In 821 the emperor Michael allowed him to return to Constantinople, where he indulged a freedom of speech that obliged him to withdraw. He died in the year 826, in his sixty-seventh year. He was a man of learning, and author of many works, which were published by Sirmond, in Greek and Latin, at the end of his own works. *Dupin. Mosheim. Gen. Biog.*

THEODORET, a learned prelate of the Greek church, was born at Antioch about the year 386, and placed at the age of seven in the monastery of St. Euprepus. He was educated under Theodore of Mopsuestia and John Chrysostom, and from his youth addicted himself to all the austerities and exercises of a monastic life. Upon the death of his parents, he distributed his whole property among the poor. In the year 420, or 423, he was consecrated, against his own inclination, bishop of Cyrus in Syria, in the Euphratensian province, the inhabitants of which were ignorant and barbarous, and notorious for their superstitious practices and heretical errors. Theodoret laboured industriously and successfully in enlightening and reforming them. In his own conduct he was an exemplary pastor; and in every thing

thing that related to his own gratification, he was self-denying and frugal, that he might possess more ample means of relieving the poor and promoting works of public utility. No bishop of his time was more active in performing the duties that pertained to his profession and station, or had greater influence in every kind of public business, particularly of an ecclesiastical nature. He was prudent in counsel, pacific in his temper, and always disposed to compromise differences that occurred, and to recommend mutual forbearance and union among contending parties. But like other pacificators, he could not escape obloquy and harsh treatment. Between him and Cyril, however, an irreconcilable antipathy subsisted, as was generally the case between the Eastern and Egyptian bishops; and this antipathy was manifested, even after Cyril's death, by his successor Dioscorus, who caused Theodoret to be anathematized, and to be deposed in a general synod at Ephesus. In the reign of the emperor Marcian, a general council was assembled at Chalcedon; and this council decreed, that Theodoret was worthy to hold his see, and he was accordingly restored to the church of Cyrus. He died, without any further molestation, in the beginning of the reign of the emperor Leo, A. D. 457 or 458.

Theodoret bears a high rank among the ancients as a commentator on the scriptures for the purity of his Attic style, and the clearness and good sense of his explanations. He wrote commentaries upon most parts of the sacred scriptures. His canon of the Old Testament was very little, if at all, different from that of the Jews. With regard to the New Testament, it appears that he received only four gospels, the book of Acts, which he ascribed to St. Luke, and fourteen epistles of the apostle Paul, upon which he wrote commentaries; digesting them according to the order of time in which they were written, and noticing the places from which they were sent. He has seldom quoted the Catholic epistles, though they are not wholly overlooked. He seems to have received the epistle of James, the first of Peter, and the first of John; but there is no certain proof that he received the book of the Revelation, or the other four Catholic epistles: so that we may conclude, that his canon of the New Testament was the same with that of the Syrian Christians. His "Ecclesiastical History," comprised in five books, may be considered as a supplement to those of Socrates and Sozomen; beginning where that of Eusebius ends, at the rise of Arianism in 322 or 323, and terminating in 428. Its style, according to Photius, is clear and sublime, but too much abounding in metaphors. It is deficient in chronological precision, but contains many valuable documents, and some remarkable circumstances, which other ecclesiastical historians have omitted. His "Philotheus," or treatise on the monastic life, the genuineness of which some have questioned without sufficient reason, relates the actions and extols the piety of the Eastern monks, and abounds with instances of the credulity and superstition of the times. In his work entitled "Of Heretical Fables," in five books, he distributes the different heresies into classes, and concludes with a statement of the faith of the Catholic church. "The Cure of the false Opinions of the Heathens," in twelve discourses, is a learned and valuable apology for Christianity. Lardner has given copious extracts from this performance, which merit high commendation. His other works consist of letters and tracts on different theological subjects. They are all comprised in the best edition of his writings, which is that of Father Sirmond, in four vols. fol. Gr. and Lat. printed at Paris in 1642. To these the Jesuit Garnier added a fifth in 1684. Beaufobre gives the following candid account of Theodoret. "Theodoret is, in my opinion, one of the most

valuable of the Fathers. He is learned; he reasons well, especially in his dialogues against the Greek heresies of his times: he is a good literal interpreter of the scriptures. I cannot but admire his prudence and moderation, when I consider that he ended his ecclesiastical history at the time when the Nestorian disputes, in which he was so deeply interested, begun. But, I fear, his zeal against heretics imposed upon him almost as much, as his admiration of the heroes of the Ascetic life, with whom he was charmed. Monasteries have undoubtedly sent forth great men into the world; but the disciples of the monks contracted in their youth a superstitious disposition which is scarcely ever shaken off; and the weak side of this able man seems to have been an excessive credulity." Dupin. Mosheim. Lardner. Beaufobre.

THEODORIC I., king of the Visigoths, was the son of Alaric, and in 419 succeeded Wallia in the kingdom established in the south of France. After raising the siege of Arles, he made peace with the Romans, and was subsidized by them in the Spanish war; but being desirous of renewing his attempts in Gaul, he took an opportunity, in 435, of resuming his hostilities against them, and laid siege to Narbonne; but being compelled to raise the siege, he was under a necessity of directing his attention to the safety of Toulouse, his own capital, which was invested by a body of Huns, under the command of count Litorius. In a very sanguinary engagement with the assailants, he totally routed them, and took Litorius prisoner; who was first exposed to the insults of the populace at Toulouse, and then thrown into a dungeon, where he died. After this event, Theodoric made peace with the Romans. His rank among the sovereigns of that period was respectable; and both his sons and daughters were well educated. The latter formed matrimonial connections with the eldest sons of the kings of the Suevi and Vandals, who reigned in Spain and in Africa. But these connections proved unfortunate. The husband of the Suevian princess was massacred by his brother; and the Vandal princess, being suspected of a design to poison her father-in-law, Genferic, was doomed to lose her nose and ears, and in this mutilated condition was sent home to her father. Theodoric eagerly sought an opportunity for revenging this cruel insult. With this view, the Visigoths and Romans formed an alliance to resist Attila the Hun, who, instigated by Genferic, invaded Gaul in 441; and Theodoric, at the head of his army, marched to the relief of Orleans, which was besieged by the Huns. In their way the hostile armies met on the plains of Chalons, and a dreadful battle ensued. Theodoric was wounded by a Goth in the service of Attila, and being dismounted, was trampled to death under the feet of his own cavalry. When his body was found, his funeral rites were performed in the face of the retiring enemy.

THEODORIC, king of the Ostrogoths, surnamed the *Great*, was a descendant of the Gothic race of the Amali, and born near Vienna, A. D. 455. At the age of eight years, he was sent to Constantinople as a hostage for the fulfilment of the subsidiary treaty formed by the emperor Leo with the Goths. Here he had an opportunity of acquiring that character which he sustained among the princes of that age: but his means of instruction must have been very limited, when it is considered that, though he excelled in all military exercises, he was so badly taught, as not to be able to write his own name. After ten years' residence at the court of Leo, he returned to his father, Theodimir, who was then the sole ruler of the Ostrogoths, in whose service he distinguished himself by his martial spirit. Upon the death of his father, in 475, the crown devolved on Theodoric. The emperor

peror Zeno, wishing to secure the attachment of the young prince, invited him to his court, and conferred upon him the rank of patrician. After having rendered substantial service to the emperor, he was reduced to the necessity of deserting the Roman cause, and forming an alliance with Theodoric, the son of Triarius. Having been altogether neglected by Zeno, he marched in an hostile manner into the fertile provinces of Thrace, which he laid waste with wanton cruelty. In the war that ensued between the empire and the Goths, a variety of events occurred; but, upon the whole, Theodoric became more and more formidable, and by the death of the son of Triarius, he was placed at the head of his nation. Such was the power he acquired, that the emperor found it necessary to cede to him part of Lower Mœsia and Lower Dacia, and to honour him with the consulate, which office he discharged at Constantinople. But conceiving that he was an object of jealousy, and that his life was in danger, he withdrew into Thrace, and afterwards avowed himself an undisguised enemy to the empire. Declining to lay siege to Constantinople, he determined, as it is said, at the suggestion of Zeno, to turn his forces against Odoacer, who having deposed Augustulus, the last Western emperor, had assumed the title of king of Italy.

In the year 488, Theodoric, having collected together all the swarms of Goths that had successively arrived on the frontiers of the empire, set out on his Italian expedition; and after encountering many difficulties in his progress, descended from the Italian alps, and reached the banks of the Sontius near Aquileia. Here, in August 489, he attacked Odoacer's numerous host, and forced him to retreat as far as the plains of Verona. The result of a second engagement was a complete victory on the part of the Goths, which compelled Odoacer and his fugitives to take refuge within the walls of Ravenna, while the conqueror obtained possession of the cities of Pavia and Milan. But, as the fortune of war is uncertain, one of Odoacer's commanders, having deserted to Theodoric, proved treacherous, and induced several of the officers of the Gothic king to join his former master. Odoacer, having also gained an accession of other fugitives from the Gothic service, recovered Milan, and obliged Theodoric to immure himself in Pavia. Theodoric, however, in this crisis of danger, obtained a powerful reinforcement from Alaric II. king of the Visigoths, settled in Gaul, and attacking Odoacer on the Adna, totally defeated him. Upon this disaster, Odoacer fled to Ravenna; where, in the autumn of 492, he was besieged by Theodoric, who had made himself master of all Italy, except this city. In the following spring, Odoacer was reduced to the necessity of proposing terms of accommodation, with which Theodoric complied; and the consequence was the surrender of Ravenna to the Gothic army. It was stipulated between these two sovereigns, that they should govern Italy with equal authority. Such a stipulation was not likely to produce any permanent effect; and it was very soon violated on the part of Theodoric, by an act which entails on his memory eternal dishonour. Having invited Odoacer to a banquet, he stabbed him, as it is said, with his own hand, under a pretext that his dead rival had formed a similar design with regard to himself. After this event, Theodoric assumed the ensigns of royalty, and caused himself to be proclaimed by his army "king of Italy." This assumption was reluctantly confirmed by Anastasius, the successor of Zeno. The manner in which he exercised the royal authority, however unwarrantable the means by which he acquired it, placed him far above all the sovereigns of that age. Sicily having been united to Italy by a voluntary cession, Theodoric sheathed the sword of war, and cultivated alliances with neighbour-

ing powers for the security of his kingdom. He established peace with the imperial court at Constantinople, married a daughter of the king of the Franks, and bestowed his own two daughters by a concubine, one on the king of the Visigoths, and the other on the son of the king of the Burgundians, and his sister on the king of the Vandals. He secured the attachment of his soldiers by assigning to them a third part of the lands of Italy; and he restricted the military profession to his countrymen the Goths, whilst he encouraged industry and the arts of peace among his Italian subjects. The Goths held their lands and benefices as a military stipend, in consideration of which they were engaged to march on a summons under their provincial officers: and the whole extent of Italy was distributed into the quarters of a well-regulated camp. The civil offices were committed to the native Italians; and the form of government, and distribution of magistracies and of provinces, which had prevailed under the emperors, were continued; so that the transfer of power from the Romans to the Goths was scarcely perceived. The taxes remained the same, and on occasion of any public calamity, were remitted. He fixed his ordinary residence at Ravenna; and when he removed his court, it was to Verona. In the year 500 he visited Rome, and was treated with respect. He issued edicts for preventing the demolition of ancient monuments, and appropriated revenues to the repair of public edifices. He decorated other cities of Italy; and it has been said, that, after the flourishing times of Rome, this country was never so prosperous and happy. He provided a fleet for guarding the country against maritime attacks: and those wars by land in which he engaged, were terminated without disturbing the peace and hazarding the security of Italy. By his prudent conduct, and military achievements, he maintained the balance of power in the West, till it was overthrown by the ambition of Clovis, who defeated and put to death Alaric, the Visigoth king: nevertheless he saved the remainder of his family and people, and checked the career of the Franks.

Theodoric, with regard to his religious sentiments and profession, was an Arian; but he manifested no ardent zeal for making proselytes to his own opinions, nor did he molest others in their profession. Such was the government of Theodoric, that it reflected a short-lived lustre on the Gothic name, and established an era of public happiness which it is pleasing to contemplate. His secretary Cassiodorus, who was himself a man of erudition, and who caused his untaught master to patronize literature, has recorded in his twelve books of Epistles, the events at which we have here glanced. It must not be disguised, however, that the reign of Theodoric was not exempt from the evils inseparable from a despotism upheld by military power. The yoke of a foreigner was galling; and more especially that of a foreigner who was considered as a barbarian and a heretic. The tolerant principles of Theodoric did not accord with the orthodox zeal of his subjects; and his punishment of some outrages committed against the Jews, who were settled in the cities of Italy, was represented as a persecution of the church. An intolerant edict against the Arians, issued by the Byzantine court, provoked the king to retaliate on the Catholics under his jurisdiction; and shortly before his death an order was prepared to forbid the exercise of the Catholic worship in Italy after a certain day. In the mean time, jealousies of the senatorial party in Rome, and of their connection with the imperial court, took possession of the mind of Theodoric, who was made suspicious by age; and an instance of tyranny inflicted upon two exemplary characters, says one of his biographers, is unhappily the last act recorded of a sovereign distinguished for the mildness and equity of his administration. For an ac-

count of the circumstances to which we here refer, see the article *BOETHIUS*. Theodoric, at the close of life, reflected without doubt with remorse and self-reproach on his conduct towards Boethius and Symmachus. It is said that, whilst he was sitting at table, he perceived the gaping head of a large fish, which was served up before him, and at the sight exclaimed, that he beheld the angry and menacing countenance of Symmachus. Then probably did that fever commence, which being attended with a dysentery, terminated his life within three days, August, A.D. 526, in the 72d year of his age, and the 34th of his reign, dating its commencement with the death of Odoacer. His dominions were divided by his testament between his two grandsons, Amalaric and Athanaric, assigning the Rhone as their boundary; and the guardianship of the latter, who was king of Italy, was entrusted with his daughter Amalafuntha. He erected to his memory a splendid monument in a conspicuous situation above the city of Ravenna. *Anc. Un. Hist.* Gibbon's *Rom. Hist.* *Gen. Biog.*

THEODORIC, or *THIERRY of Niem*, an ecclesiastical writer, was born at Paderborn, and served Gregory XI. Urban VII. and several succeeding popes, as under-secretary. The time in which he lived may be inferred from his "History of the Schism of the Popes," written between the years 1400 and 1410; in which work he says that he had lived near thirty years at the court of Rome, and that being then worn down with age, it was his intention to withdraw from public business. This work, composed in Latin, comprised, in three books, the interval from the death of Gregory XI. to the election of Alexander V. Another work relating to the same subject was entitled "Nemus Unionis." In 1412 he published a "Treatise on the Rights and Privileges of the Emperors in the Investiture of Bishops and Abbots." He also wrote a journal of the proceedings of the council of Constance, ending in June 1416, in which year he died. From his own observation, he exhibits a shocking picture of the court of Rome, and the clergy of that period. Dupin. Moreri.

THEODOROPOLIS, in *Ancient Geography*, a town of Mœsia, founded by the emperor Justinian, who called it after the name of his wife.

THEODORUS, in *Biography*, a Cyrenaic philosopher, was a disciple of Anicerris, and for speaking freely concerning the gods, he was stigmatized with the appellation of Atheist, and banished from Cyrene. At Athens, where he sought refuge, he was protected by Demetrius Phalereus, and gained access to the court of Ptolemy Lagis. Afterwards, upon his return to Athens, he is said to have suffered death by hemlock; but it has been disputed whether atheism, or contempt of the Grecian superstitions, was the cause of his death. He is joined by Sextus Empiricus with Eumerus, and others, who maintained, that those who were esteemed gods, were men who had possessed great power on earth; and Clemens Alexandrinus expresses his surprise, that Eumerus, Nicanor, Diagoras, Theodorus, and others, who had lived virtuously, should be pronounced atheists from their opposition to gentile polytheism. Brucker by Enfield, vol. i.

THEODORUS, an Athenian flute-maker, the father of Isocrates the orator. How great the demand was at this time for flutes at Athens, may be conceived from a circumstance mentioned by Plutarch in his life of the orator. His father, says he, acquired wealth sufficient by his business, not only to educate his children in a liberal manner, but also to bear one of the heaviest public burdens to which an Athenian citizen was liable; that of furnishing a choir or chorus for his tribe, or ward, at festivals and religious ceremonies. See *ISMENIAS*.

THEODOSIA, in *Ancient Geography*, a town situated on the S.E. coast of the Tauric Chersonesus. See *CAFFA*.—Also, a town of Asia, in the Greater Armenia.

THEODOSIOPOLIS, a town of Asia, in the Greater Armenia, on the frontiers of Perfermenia.—Also, a town of Asia, in Mesopotamia, upon the river Chaborras.

THEODOSIUS I. surnamed the *Great*, in *Biography*, a Roman emperor, was the son of an eminent general of the same name, who was executed for treason at Carthage in the year 376. He was born about the year 346, as some say, at Caucha, in Gallicia, or according to others, at Italica, near Seville. His education was liberal, and he learned the art of war by serving under his father, both in Britain and in Africa. The death of his father put a temporary stop to his military career, and he retired to Spain for the improvement of his mind and the culture of his paternal estate. He was in this situation when the emperor Valens was killed in battle, and the empire was left in great danger. Thus circumstanced, the other emperor, Gratian, sent for Theodosius, and in January, A.D. 379, declared him his partner in the empire. To him was committed the care of Thrace and the eastern provinces, threatened at this time by numerous bands of barbarians. The result of his campaign was, that some of the Goths submitted to his authority, and the rest evacuated Thrace. Having been baptized in the second year of his reign, in consequence of a dangerous disease, he became a zealous advocate for the orthodoxy of the church, and was much applauded by the Catholics. He issued an edict, enjoining the subjects of his government to adhere steadfastly to the religion taught by St. Peter, which asserts the sole deity of the Father, the Son, and the Holy Ghost, under an equal majesty and a pious Trinity; and to assume the title of Catholic Christians, all other persons who did not embrace this doctrine being branded as infamous heretics, and their churches being declared conventicles. It also announces, that besides the condemnation of divine justice, these persons must expect the severe penalties which his authority, guided by heavenly wisdom, shall think proper to inflict upon them. This declaration, so incompatible with the genuine spirit of the religion and the profession in which he had been initiated, was followed by correspondent deeds. When he entered Constantinople, after the campaign of 380, his first act was to remove the patriarch Demophilus, and to offer him the alternative of subscribing the Nicene creed, or resigning all his dignities to the orthodox party. The patriarch nobly chose the latter alternative, and withdrew into exile. Soon after he issued a decree for expelling from their churches all the clergy who refused to accept the Nicene creed, and he appointed a military force for the execution of it. By these measures the emperor succeeded, without tumult or bloodshed, in establishing, through the provinces of the East, the Catholic faith upon the ruins of Arianism. So assiduous was the emperor in this exercise of his zeal, that he is said to have promulgated, in fifteen years, at least fifteen penal edicts against heretics, some of which denounced capital punishment: and it is moreover asserted, that the office of inquisitors of the faith was first instituted in his reign. It has been affirmed, however, that he chiefly meant intimidation, and that the threatened penalties were seldom carried into effect.

The military ardour of this emperor seems to have been exercised with greater prudence than his religious zeal. In order to liberate the provinces from the barbarians, he contrived to weaken their strength by fomenting divisions among their chiefs, and he conciliated others by his generosity: so that about four years after the death of Valens, he signed a capitulation with the whole nation of the Goths; and

and as their own country was occupied by the Huns, he permitted them to settle in Thrace and Mœtia, with exemptions from tribute and taxes. With Maximus, who had revolted against the emperor Gratian, Theodosius entered into a treaty, by which it was stipulated that the usurper should retain the countries beyond the Alps, and that Valentinian, the brother of Gratian, should be secured in the possession of the remaining part of the Western empire. Maximus was acknowledged by Theodosius as his colleague in the Roman empire, and Arcadius, the son of Theodosius, though only eight years of age, was admitted to a share in the purple. At this time Theodosius issued some severe edicts against heathen idolatry: and he passed a law against the marriage of cousins-german, which condemned both parties to be burnt alive, and which declared their children illegitimate. In 386, the Gruthungi, or Ostrogoths, in their attempt to pass the Danube, were defeated with great slaughter. In 387, Maximus invaded Italy; and Valentinian, deserted by his subjects, took refuge in the dominions of Theodosius, who married Galla, the sister of that emperor. In this year the people of Antioch, having without effect remonstrated against the proceedings of Theodosius, both as to religious matters and the imposition of an extraordinary tax, broke out into an insurrection; threatened the life of the governor; and, disappointed in this effort of their rage, demolished the statues of the emperor and his family. Theodosius, in the first transports of resentment, upon receiving intelligence of their conduct, ordered the city to be laid in ashes, and all the inhabitants, without discrimination of age or sex, to be put to the sword. Upon cooler reflection he revoked this sanguinary order, and contented himself with degrading Antioch from the rank of a city, and depriving the inhabitants of their customary largess of bread. Those who upon inquiry were found guilty, were condemned to death. But by the intercession of the bishop of Antioch, and other holy men, the culprits were pardoned, and the city restored to all its privileges.

Theodosius, on a visit to Valentinian at Thessalonica, prevailed on him to renounce Arianism, and to adopt the Nicene faith; and determined to take up arms in his cause against Maximus. After several successful encounters with the usurper, he was deposed of all his imperial ornaments, and dragged like a malefactor into the presence of Theodosius, who caused him to be beheaded. His son Victor was also put to death; and the civil war terminated A.D. 388. In consequence of these events, Theodosius became the sole head of the Roman world; and he invested the son of Valentinian, now a minor, with the sovereignty of the provinces wrested from him by Maximus, and also with the possession of Gaul, Spain, and Britain, of which Gratian had been deprived by this usurper. Theodosius remained three years in Italy, giving vigour to the law, correcting abuses, and adopting a variety of measures for totally eradicating paganism.

In 390, a sedition took place at Thessalonica, which was followed by many disastrous consequences, and by the exercise of a degree of cruelty, which the emperor was obliged to expiate by a public penance. About this time he took advantage of a religious tumult at Alexandria for demolishing the famous temple of Serapis, and of all the heathen temples throughout Egypt. He also issued a final edict against the ancient worship.

In 392, the emperor Valentinian was murdered by his general Arbogastes, and Eugenius was placed on the throne. When this measure was announced to Theodosius, he prepared for war; and having obtained a favourable answer from a holy hermit in Thebais, whom he consulted, issued new

edicts against heresy, and abrogated the ancient penalties of treason against those who uttered seditious words against the prince; he openly took up arms, A.D. 394, and forcing the passage of the Alps, descended into Italy. He met Eugenius and Arbogastes with a great force, and after several conflicts, Eugenius was totally defeated, and put to death by the soldiers. His children, however, and those of Arbogastes, who put an end to his own life after the battle, were treated humanely, and removed to their paternal possessions.

After this success, Theodosius sent for his son Honorius to Milan, and declared him emperor of the West; Arcadius having been already put in possession of the Eastern empire. In January 395, Theodosius terminated his life by a dropical disorder at Milan, at the age of fifty years, and at the close of the sixteenth year of his reign.

The name of Theodosius has been celebrated, but his character has been very differently appreciated. Politically considered, whilst it exhibits many virtues and excellencies, it is chargeable with many errors and obliquities. Connected with the ecclesiastical interests of the period in which he lived, his conduct on various occasions was altogether indefensible; and we may add, that how much soever he has been extolled by partial historians, his bigotry and intolerance were very reprehensible. *Anc. Un. Hist. Gibbon's Rom. Hist. Gen. Biog.*

THEODOSIUS II., son of the emperor Arcadius, and grandson of the preceding Theodosius, was born in the year 401; and being of feeble faculties, was educated merely to sustain the pageantry of a throne; or, as Mr. Gibbon expresses it, "to represent with grace and dignity the external figure of a Roman emperor." His only active pursuit was hunting; and his more private exercises were painting and carving, making elegant transcripts of religious books, and singing psalms. He also fasted, gave credit to miracles and doctrines presented to his faith, and paid due homage to all the dead and living saints of the Catholic church. His disposition was gentle and kind; in his conduct he was free from vices, and yet, as his biographer says, "he did not rise to virtues." Upon his father's death, A.D. 408, he succeeded him in the Eastern empire. To the influence of his sister Pulcheria, superior in talents to himself, he implicitly submitted; and in 414 he raised her to the rank of Augusta, and entrusted with her the reins of government. By her selection and recommendation he married, A.D. 421, the celebrated Athanasia, afterwards named Eudocia. The war which broke out in 422, in consequence of a persecution excited by the Magi against the Christians, terminated in a truce of a hundred years, and a division of the kingdom of Armenia between the contending powers. On the death of the emperor Honorius, in 423, the throne of the West was usurped by John; but Theodosius restored it to its proper heir, Valentinian III., who afterwards married his daughter. When Attila made an irruption into the Roman empire, he was opposed by Theodosius, whose armies were repeatedly defeated: and Theodosius himself was compelled in 446 to make a humiliating treaty with the king of the Huns. By one of his favourites, the eunuch Chrysfapius, he was induced to free himself from Attila by assassination, but the treachery was defeated, and he received a just and severe reprimand from the barbarian. Soon after this mortification, he died in consequence of a fall from his horse, A.D. 450, in the fiftieth year of his age. What his grandfather had done towards the subversion of the Pagan religion in the East, Theodosius completed. He always approved himself a dutiful son of the church, but he is said to have favoured the Eutychian heresy. His principal merit was the publication, A.D. 438, of the

“Theodosian Code.” *Anc. Un. Hist.* Gibbou. *Gen. Biog.*

THEODOSIUS, an eminent mathematician, was born at Tripoli, and flourished about the second or third century. On the doctrine of the Sphere he wrote three books, containing a considerable number of propositions, demonstrated in the pure geometrical manner of the ancients, and establishing the geometrical principles of astronomy. Ptolemy and succeeding writers availed themselves of these books, which were translated by the Arabians from the original Greek into their own language. They were afterwards translated from the Arabic into Latin, and printed at Venice; but the defects of the Arabic version were supplied in a more complete edition, published in Greek and Latin at Paris in 1556, 4to. by John Pena, regius professor of astronomy. On this work there have been many comments; but the edition of Theodosius's Spherics now generally used is that of Dr. Barrow, published in 1675, illustrated and demonstrated in a new and concise method. Theodosius was also the author of two other treatises, one “*De Habitationibus*,” and the other “*De Diebus et Noctibus*.” Greek copies of these were preserved in the king's library at Paris, and a Latin edition was published by Peter Dafypodius in 1572. *Montucla Hist. des Mathem.*

THEODULF, a learned prelate of a Gothic family, was a native of Cisalpine Gaul; and being invited to France by Charlemagne, he was promoted to the bishopric of Orleans, A.D. 794, and the abbacy of the monastery of Fleury. He continued in favour at court till the death of Charlemagne, and for some time under the emperor Lewis. But being implicated in the conspiracy of Bernard, king of Italy, against Lewis, he was committed to prison at Angers, where he remained in confinement for three years. After his liberation, and before his return to his diocese, he died at Angers, about the year 821. Theodulf was the friend of Alcuin, and deserves honourable mention as one of the votaries and promoters of literature in a dark age. He was the author of several works, published by Father Sirmond, in 1646, 8vo. One of his hymns, beginning

“Gloria, laus et honor tibi fit, Rex Christe Redemptor,”

has been adopted by the Catholic church for the service on Palm-Sunday. *Dupin. Gen. Biog.*

THEOGAMIA, Θεογαμία, in *Antiquity*, a Sicilian festival, in honour of Proserpine, which seems to have been instituted in memory of her marriage with Pluto.

THEOGNIS, in *Biography*, a Greek poet, was a native of Megara, in Attica, and flourished about the year B.C. 546. He has been denominated “*Gnomologus*,” or the writer of sentences: and we have extant a work written by him, without order, consisting of moral maxims or precepts, simply expressed and destitute of poetical ornaments, versified probably for assisting the memory. Athenæus reckons him among the advocates for licentious pleasures; and Suidas refers to a work of his composition, entitled “*Exhortations*” or “*Admonitions*,” which contained various impurities. In the verses that now remain, nothing of this kind appears; so that if the charge be true, they must have undergone castigation. “*The Sentences of Theognis*” have been often printed by themselves, and with the works of other minor Greek poets. Among the best editions are those of Camerarius and Sylburgius. *Vossii Poet. Græc. Gen. Biog.*

THEOGONY, formed from Θεός, *God*, and γέννησις, *geniture, seed, offspring*, that branch of the heathen theology which taught the genealogy of their gods.

Hesiod gives us the ancient theogony, in a poem under

that title. This poem treats of the origin and descent of the gods; or rather, under the allegorical dress of theogony, represents the formation of the world, and the history of eminent men. The plan of this work is intricate and confused. (See *HESIOD.*) The writer seems to have made use of several different theogonies, and to have blended them together with little regard to consistency. He also frequently adds, for the sake of poetical ornament, fictions of his own, which have no relation to the history and origin of the world. Aristophanes, in his comedy of “*The Birds*,” has introduced a description of the formation of the world, which was borrowed, without doubt, from the ancient theogonies; but it deserves little attention. All the theogonies make an eternal chaos the origin of all things. Thus Ovid. *Met. l. 1. v. 5.*

“Ante mare, et terras, et quod tegit omnia cælum,
Unus erat toto naturæ vultus in orbe,
Quem dixere Chaos, rudis indigestaque moles,
Nec quicquam nisi pondus iners, congestaque eodem
Non bene juncturam discordia femina rerum.”

“Ere sea and earth, and heav'n's high canopy
Were form'd, great Nature's face was one;
A lifeless, rude, and undigested mass
Of jarring seeds in one wild chaos lay.” See *CHAOS.*

Whether, besides this chaotic mass, the ancient theogonies suppose an infinite, active, intelligent principle, who from the first matter formed the universe, is a question that has occasioned much debate. It is evident, upon the most cursory review of the ancient theogonies, that God, the great Creator of all things, is not expressly introduced; but it is doubted, whether the writers meant to exclude him from their system, or indirectly to suppose his existence, and the exertion of his power in giving motion to matter. In the solution of this question, it ought to be considered, whether the theogonists supposed God to have existed before chaos, and to have created it from nothing; or thought him to have sprung from a pre-existing chaos; or conceived God and matter to have been two co-existing and independent principles: whether they imagined God to have been the soul of nature, informing the eternal mass of matter; or were of opinion, that God sent forth matter as an emanation from himself; if the latter, whether this emanation was the effect of necessity, or of a free act of volition; whether it was from all eternity, or began at some limited period of duration. It must also be inquired, whether, according to the doctrine of the theogonies, a divine mind interposed in the formation of the world, or the effect was produced by the necessary laws of motion acting upon homogeneous and heterogeneous portions of matter. If the latter of these was their doctrine, it is to be farther considered, whether it necessarily follows, that they denied the existence of God, or whether it may not be supposed, that, neglecting all consideration of deity, they only endeavoured to explain the physical formation of the world, by laws originally impressed upon matter by the author of nature.

The theogonies certainly do not suppose God to have been prior in the order of time to matter: they speak of chaos as eternal, and seem to have been wholly unacquainted with the doctrine of creation from nothing. But, on the other hand, they never suppose the Deity to be derived from chaos: for Jupiter is not to be confounded with the Supreme Being, but merely to be considered as the chief of those inferior divinities, who, according to the Grecian theology, were either portions of the divinity, inhabiting and animating parts of nature, or departed spirits of heroes and illust.

illustrious men, exalted to divine honours. There is no sufficient proof, that Orpheus, Hesiod, or any other Grecian cosmogonist, supposed two independent principles in nature: for, though they ascribe the origin of evil to Chaos, they might, nevertheless, be of opinion, as we shall find to have been the case with many later philosophers, that matter is derived from God.

There were, perhaps, different opinions among the ancient cosmogonists, concerning the first cause of nature. Some might, possibly, ascribe the origin of all things to a generating force, destitute of thought, which they conceived to be inherent in matter, without looking to any higher principle. But it is probable, that the general opinion among them was that which had prevailed among the Egyptians and in the East, and was communicated by tradition to the Greeks, that matter, or chaos, existed eternally with God, and that by the divine energy of emanation, material forms were sent forth from him, and the visible world arose into existence. This principle being admitted, the whole system of the ancient theogonies appears consistent, and a satisfactory explanation may be given of most of the Grecian fables. Upon this supposition, the sum of the doctrine of the theogonies, divested of allegory and poetry, will be as follows:

The first matter, containing the seeds of all future being, existed from eternity with God. At length, the divine energy upon matter produced a motion among its parts, by which those of the same kind were brought together, and those of a different kind were separated, and by which, according to certain wise laws, the various forms of the material world were produced. The same energy of emanation gave existence to animals and men, and to gods who inhabit the heavenly bodies, and various other parts of nature. Among men, those who possess a larger portion of the divine nature than others, are hereby impelled to great and beneficent actions, and afford illustrious proofs of their divine original, on account of which, they are after death raised to a place among the gods, and become objects of religious worship.

Upon the basis of these notions, it is easy to conceive, that the whole mythological system, and all the religious rites and mysteries of the Greeks, might be founded. Brucker's Hist. Phil. by Enf. vol. i.

Among the most ancient writers, Dr. Burnet observes, that theogony and cosmogony signified the same thing. (See COSMOGONY.) In effect, the generation of the gods of the ancient Persians, fire, water, and earth, is apparently no other than that of the primary elements.

THEOLOGICAL CRITICISM. See CRITICISM.

THEOLOGICAL Prebend. See PREBEND.

THEOLOGIUM, formed from $\Theta\epsilon\omicron\varsigma$, and $\lambda\omicron\gamma\omicron\varsigma$ *speech*, or *discourse*, in the ancient theatre, was a place, or little stage, above that on which the ordinary actors appeared. See THEATER.

The theologium was the place where their gods appeared. It also included the machines on which they descended, and from which they spoke.

There was a theologium required for the representation of the Ajax of Sophocles, the Hippolitus of Euripides, &c. Scal. Poet. lib. i. cap. 1.

THEOLOGY, compounded of $\Theta\epsilon\omicron\varsigma$, *God*, and $\lambda\omicron\gamma\omicron\varsigma$, *discourse*, *divinity*; a science, which instructs us in the knowledge of God, and divine things; or which has God, and the things he has revealed, for its object.

Theology is a science which shews us what we are to believe of God, and the manner in which he would be served.

It is divided into two branches, the *natural*, and the *revealed* or *supernatural*.

THEOLOGY, Natural, is the knowledge we have of God from his works, by the light of nature, and reason.

THEOLOGY, Supernatural, is that which we learn from revelation. See RELIGION.

THEOLOGY, Positive, is the knowledge of the holy Scriptures, and of the signification of them, conformably to the opinions of the fathers and councils; without the assistance of any argumentation. But some will have it, that this ought to be called *expositive*, rather than *positive*.

THEOLOGY, Moral, is that which teaches us the divine laws relating to our manners and actions; in contradistinction to

THEOLOGY, Speculative, which explains and establishes the doctrines of religion, as objects of faith.

THEOLOGY, Scholastic, or *School*, is that which proceeds by reasoning; or that derives the knowledge of several divine things from certain established principles of faith. See SCHOLASTIC Divinity.

The ancients, according to Varro, Scævola, and Plutarch, had a three-fold theology; the first $\mu\upsilon\theta\iota\kappa\eta$, *mythic*, *fabulous*, which flourished among the poets; and was chiefly employed in the theogony, or genealogy, and history of the gods: to whom all things were attributed, which men, and even the vilest of men, could be guilty of. Nevertheless, the popular religion and worship were in a great measure founded upon that mythology, which run through the whole of their religion, and was of great authority with the people. Many unexceptionable proofs of this are produced by Dr. Leland, in his "Advantage and Necessity of the Christian Revelation," vol. i. part i. chap. 6.

The second, $\pi\omicron\lambda\iota\tau\iota\kappa\eta$, *political*, or *civil*, was that established by the Roman laws, and chiefly embraced by the politicians, priests, and people, as most suitable and expedient to the safety, quiet, and prosperity of the state. This, though not the true, was the vulgar theology, and constituted the public and authorized religion. It was that which the philosophers themselves, whatever private opinions or speculations they might entertain, or dispute of in their schools, universally conformed to in their own practice, and also exhorted others to do so. Varro informs us, that this theology particularly determined what gods they were publicly to worship, what sacred rites they were to observe, and what sacrifices to offer.

Although even the vulgar among the Pagans seem, in general, to have had some notion of one supreme God, yet their theology was properly polytheism; and the providence they acknowledged, was the providence, not of one God, but of many gods. The learned Dr. Cudworth, who seems inclined to put the most favourable construction upon the Pagan theology, acknowledges, that the civil theology, as well as the poetical, had not only many fantastical gods in it, but an appearance of a plurality of independent deities; several being made supreme in their respective territories or functions. Aristotle (Oper. tom. i. p. 1246. edit. Paris, 1629) intimates, that according to the laws of cities and countries, that is, in the civil or political theology, there seems to be no one absolutely powerful or all-perfect being, but a plurality of gods, one of whom is supposed to be more powerful in one respect, and another in another respect. Besides, the public religion was made up partly of the physical, and partly of the poetical theology. Those poetical fables, which Varro censures as unworthy of the gods, and as ascribing to them actions which none but the vilest of men

men would be guilty of, were not only permitted to be acted on the public theatres, and heard with pleasure by the people, but they were regarded as things pleasing to the gods themselves, by which they were propitiated and rendered favourable; and accordingly they were taken into the public religion. Games were celebrated, and plays were founded upon them; and the public games and plays were on certain occasions considered as acts of religion, encouraged by their deities, and celebrated in honour of them. It is also justly observed, that the images, forms, habits, and ornaments of their gods, their different sexes and ages, and the sacred festivals instituted to their honour, had all of them a reference to the fables of the poets and mythologists, and were founded upon them; so that the civil and the fabulous theology might each of them be called civil, and each fabulous. Hence proceeded many absurd and ridiculous, and many immoral and inhuman rites, which were made use of in the worship of their gods, and which were either prescribed by the laws, or were established customs, countenanced by the magistrates, and which had obtained the force of laws, and may, therefore, be regarded as belonging to the public religion of the Pagans. See Leland's *Christian Revelation*, ubi supra, cap. 7.

The third, *evangelical, natural*, was chiefly cultivated by the philosophers, as most agreeable to nature and reason. The physical or natural theology acknowledged one only supreme God; to which it added dæmons or spirits, as mediators between him and man.

Dr. Leland has urged a variety of considerations to prove that, notwithstanding the high encomiums which have been bestowed upon the philosophical theology of the Pagans, it was of little use in leading the people into a right knowledge of God and religion, and for reclaiming them from their idolatry and polytheism. To this purpose he observes, that, if the philosophers had been right in their own notions of religion, they could have but little influence on the people, for want of a proper authority to enforce their instructions. The affected obscurity of the Pagan philosophers was another cause which rendered them unfit to instruct the people in religion: to which it may be added, that some of them used their utmost efforts to destroy all certainty and evidence, and to unsettle men's minds as to the belief of the fundamental principles of all religion; and even the best and greatest of them acknowledged the darkness and uncertainty they were under, especially in divine matters. The philosophers themselves were also, for the most part, very wrong in their own notions of the Divinity; they very much corrupted the ancient tradition relating to the one true God and the creation of the world, and endeavoured to account for the formation of all things without the interposition of a Deity. And the opinions of those philosophers who were of a nobler kind, were chargeable with great defects: they generally expressed themselves in the polytheistic strain, and instead of leading the people to the one true God, they spoke of a plurality of gods, even in their most serious discourses; ascribing those works to the gods, and directing those duties to be rendered to them, which properly belong to the supreme. The philosophers likewise referred the people for instruction in divine matters to the oracles, which were managed by the priests: this was particularly the case with Socrates, Plato, and the Stoics.

It was an universal maxim among them, that it was the duty of every wise and good man to conform to the religion of his country; and they not only worshipped the gods of their respective countries according to the established rites, and exhorted others to do so; but when they

took upon themselves the character of legislators, and drew up plans of laws, and of the best forms of government, polytheism, and not the worship of the one true God, was the religion they proposed to establish. Moreover, they employed their learning and abilities to defend and justify the popular idolatry and polytheism. The worship of inferior deities was recommended by them, under pretence that it tended to the honour of the supreme. Some of the most eminent of them endeavoured to colour over the most absurd part of the Pagan poetical theology, by allegorizing the most indecent fables. They apologized for the Egyptian animal worship, which the generality of the vulgar Pagans in other nations ridiculed. They vindicated idolatry and image-worship, as necessary to keep the people from falling into irreligion and atheism; and besides, some of the more refined philosophers were against any external worship of the supreme God.

Many of the philosophers, and of the learned and polite Pagans, denied a providence. Of those who professed to acknowledge it, some confined it to heaven and heavenly things; others supposed it to extend to the earth and to mankind, yet so as only to exercise a general care and superintendency, but not to extend to individuals; others, again, supposed all things, the least as well as the greatest, to be under the care of providence; but they ascribed this not to the supreme God, who, they thought, was above concerning himself with such things as these, and committed the care of them wholly to inferior deities. See the illustration and proof of these several allegations by Dr. Leland, ubi supra, cap. 10—17.

THEOLOGY, *Bachelor in*. See BACHELOR.

THEOLOGY, *Mystic*. See MYSTIC.

THEOLOGY, *Polemical*. See POLEMICAL.

THEOMANTIA, *Θεομαντία*, in *Antiquity*, divination by the supposed inspiration of some deity. For a particular account of which, see Potter, *Archæol. Græc. lib. ii. cap. 12. tom. i. p. 298*.

THEON, in *Biography*, a mathematician of the Platonic school, was a native of Smyrna, and flourished under the emperors Trajan and Adrian. His mathematical treatises are said to have been written for the purpose of elucidating the philosophy of Plato; and his discourses, treating of geometry, arithmetic, music, astronomy, and the harmony of the universe, may serve to throw some light upon the Pythagorean system. Part only of his work, "De iis quæ in Mathematicis ad Platonis lectionem utilis sunt," or that which relates to arithmetic and music, has been published. The remainder, which pertained to astronomy and geometry, is said to have been preserved in the Ambrosian library at Milan. Ptolemy refers to his astronomical observations. Brucker by Enfield. Montucla *Hist. des Math.*

Another mathematician of the same name belonged to the Alexandrian school, and flourished about A.D. 365. He was the father of the learned but unfortunate Hypatia; His works are various: among these we may mention his "Recensio Elementorum Euclidis," published by Commandeni; his "Fasti Græci priores, et Fragmenti Commentarii in Ptolomæi Canonem expeditum, sive Recensio succincta Chronologica regem a Nabonassaro ad Antoninum Pium:" "Scholia in Aratum," said to be interpolated; and "Commentarius in Magnum Ptolomei Syntaxin," which is incomplete. Montucla.

THEOPASCHITES, THEOPASCHITÆ, in *Ecclesiastical History*, a sect of heretics in the fifth century, the followers of Petrus Fullensis, or Peter the Fuller, who usurped the see of Antioch; and after having been several times

times deposed, and condemned, on account of his opposition to the council of Chalcedon, was at last fixed in it, A.D. 482, by the authority of the emperor Zeno, and the favour of Acacius, bishop of Constantinople; whence they are also sometimes denominated *Fulloniani*.

Their distinguishing doctrine was, that the whole Trinity suffered in the passion of Jesus Christ.

This heresy was embraced by the Eutychian monks of Scythia, or, according to La Croze, of Egypt; who using their utmost efforts to make it obtain, raised great disorders towards the beginning of the following century.

It was condemned, at its first rise, in the councils of Rome and Constantinople, held in 483. It was again revived in the ninth century, and again condemned in a council at Rome, held in 862, under pope Nicolas I.

F. le Quien, in his notes on Damascenus, says, that the same error had been taught before Fullensis, by Apollinarius, whose disciples were the first that were called *Theopaita*, or *Theopaschita*.

THEOPHANES, in *Biography*, a Greek historian and poet, was of noble extraction, and born at Mitylene, in the island of Lesbos. About the commencement of the Mithridatic war, he is supposed to have come to Rome in his youth; and when Pompey was appointed to the chief command against Mithridates, he took Theophanes with him to record his exploits, procuring for him the citizenship of Rome, and adding to his name those of "Cornelius Balbus." It is also supposed that it was principally on his account, that on his return he visited Lesbos, and restored to the Mitylenians the privileges of which they had been deprived by the Roman senate. At Rome he connected himself with the most distinguished citizens, and he was deputed to Alexandria for the confirmation of treaties of alliance with Ptolemy Auletes. After the defeat of Pompey at Pharsalia, he accompanied him in his flight; and by his advice this commander declined to take refuge with Juba, king of Mauritania, and sailed to Egypt, where he met his fate. Theophanes afterwards joined the party of Cæsar. The most important of his writings was a "History of the Wars of the Romans, in different Countries under the Command of Pompey." Of this work there remain only five fragments, quoted by Strabo, Plutarch, and Stobæus; but Plutarch is supposed to have made great use of his authority in his life of Pompey, though he does not speak favourably of his character. He says, "Theophanes asserts, that in the private papers of Mithridates taken at Cænion, there was found a memorial, composed by Rutilius (Rufus), exhorting Mithridates to massacre all the Romans in Asia. But it is generally believed, that this was a malicious fiction of Theophanes to blacken Rutilius, whom probably he hated, because he was a perfect contrast to himself; or it might be invented by Pompey, whose father was represented by Rutilius in his history, as one of the worst of men." Rutilius was a man of such excellent character, as to be incapable of the crime with which he is charged; and without doubt such a falsification of history, for base and private purposes, is sufficient to destroy all esteem for the writer.

Of the poetry of Theophanes, which was celebrated in his time, there remain only two epigrams, inserted in the *Anthologia*. Vossius. Moreri. Gen. Biog.

THEOPHANES, GEORGE, a Constantinopolitan Greek, of a rich and noble family, married young, but from superstitious motives lived in a state of celibacy. He afterwards became a monk. At the general council held in 787, he was present, and was treated with respect. When Nicephorus, patriarch of Constantinople, was exiled by the

emperor Leo the Armenian, Theophanes paid him extraordinary honours, and was himself banished to the Isle of Samothrace, where he died in 818. His chronicle, commencing where that of Syncellus terminated, was extended to the commencement of the reign of Michael Curopalata. This was printed at Paris, with the Latin version and notes of F. Goar, under the care of Combefis, in 1665, fol. It is valuable for its facts, but displays the credulity and weak judgment of a superstitious mind. Vossius. Gen. Biog.

THEOPHANES PROKOPOVITCH (the son of Procopius), archbishop of Novgorod, a learned Russian historian, and miscellaneous writer, was born at Kiof in the year 1681, and having studied under his uncle Theophanes at the Bratskoi convent in Kiof, travelled into Italy in his eighteenth year. In three years he completed his course of preparatory study, and then returned to his native town, where he read lectures on the Latin and Slavonian art of poetry, at the seminary where he had received his education. Having assumed the monastic habit, with the name of Theophanes, he was appointed, at the age of twenty-five, prefect of the seminary, and professor of philosophy. By a Latin oration and a sermon, delivered before czar Peter the Great, he attracted his notice, and was chosen his companion in his war against the Turks. In 1711 he was made abbot of the monastery of Bratskoi, rector of its seminary, and professor of divinity. By censuring the ignorance of the clergy, and endeavouring to excite a taste for literature, he recommended himself to the czar as a proper coadjutor in his plans for reforming the church. He was accordingly placed at the head of the synod, in the new ecclesiastical establishment, the plan of which he had prepared, and in 1718 he was promoted to the bishopric of Pleskof. In 1720 he was created archbishop of the same diocese, and soon after the accession of Catharine I. he was advanced to the rank of archbishop of Novgorod, and metropolitan of all Russia; and in this station he died in 1730. This prelate was in a high degree the patron of literature, and engaged in a variety of ways, by his personal munificence and labour, in promoting it. His works were sermons and theological tracts, a treatise on rhetoric, and rules for composing Latin and Slavonian poetry, Latin verses, and more especially the Life of Peter the Great, terminating with his battle of Pultawa. Le Clerc asserts that he endeavoured to persuade Peter to introduce the Protestant religion into Russia, and that this event would have taken place, if it had not been prevented by Peter's death. The prelate's education at Rome, and the high rank he sustained in his own church, render this anecdote improbable. Coxe's Travels in Russia.

THEOPHANIA, Θεοφανία, formed of Θεος, *God*, and φαίνω, *I appear*, in *Antiquity*, a festival observed by the Delphians upon the day on which Apollo first manifested himself to them.

THEOPHANY, in *Church History*, is sometimes used in the same sense with *Epiphany*.

THEOPHILA, in *Ancient Geography*, a town of India, on this side of the Ganges.

THEOPHILE, named *Viaud*, in *Biography*, a French poet, was born at Clerac, in the Agenois, about the year 1590. By education he was a Calvinist, but in his conduct and writings he was licentious. In 1619 he withdrew to England, and unsuccessfully attempted to introduce himself to king James. After his return he abjured Calvinism, but his manners remained the same. On account of a work entitled "Le Parnasse Satirique," published in 1622, and attributed to him, in which were several pieces offensive to decency

decency and religion, he was prosecuted. Being arrested in Picardy, he was brought to Paris, and thrown into the dungeon that had been occupied by Ravillac, where he remained for two years. He was at length released by the parliament, and sentenced to banishment. The duke of Montmorency took him under his protection, and at his hotel he died in 1626. His writings are partly prose and partly verse. His verses are negligent and irregular, but they display genius and imagination. His works consist of odes, elegies, sonnets, &c.; tragedies; a dramatic dialogue on the immortality of the soul, entitled "Socrate Mourant;" apologies for himself, and letters. A collection of his poems and apologies was printed at Rouen in 1627, 8vo.; and his friend Mairet printed his French and Latin letters at Paris, in 1642, with his portrait prefixed. *Nouv. Dict. Hist. Gen. Biog.*

THEOPHILUS, emperor of Constantinople, was the son of Michael the Stammerer, and succeeded his father in 829. He began his reign with the exercise of justice in its utmost rigour, heedless not only of the claims of gratitude, but of the feelings of humanity. His father had been indebted for his life and crown to the murderers of his predecessor Leo IV. Theophilus, under a pretence of paying the debts of his father to those who had contributed to his elevation, summoned them, among other considerable persons in the empire, to his presence; and desiring the former to withdraw into an adjoining apartment, that their claims might be examined, he ordered them, on their own confession, to be capitally punished. In another case, a poor woman threw herself at his feet, complaining of the injury which she had sustained from a powerful neighbour (the empress's brother), who had raised the wall of his palace so high, that her humble dwelling was deprived of light and air. Theophilus gave her the palace, with the ground upon which it stood, and caused the offender to be stripped and scourged in the public square of the city. The effect of his singular rigour, though altogether indefensible, was, that a scrutiny of seventeen days could not discover a single crime or abuse in the court or city.

During this emperor's whole reign he was engaged in wars with the Saracens, the detail of which we shall omit. Theophilus died in 842, after a reign of more than twelve years. His zeal against the worship of images has caused his character to be treated with great severity, and his faults to be exaggerated. Although he was inexcusably rigorous in his administration, he was a reformer of manners. Of his superiority to avarice, and high ideas of the dignity of the regal character, the following anecdote furnishes an instance. Seeing one day a merchant-ship, which was deeply laden, entering the harbour of Constantinople, he asked the mariners to whom it belonged: they replied, "to the empress." "God has made me (he exclaimed) a prince, and is my wife a merchant? If princes trade, their subjects must starve:" he then ordered the vessel to be set on fire with all her cargo. *Anc. Un. Hist. Gibbon's Rom. Hist.*

THEOPHILUS, bishop of Antioch, was ordained to this see in 168 or 170, and governed it for twelve or thirteen years. In his zeal against heresy, he wrote against Marcion and against Hermogenes, and he composed other tracts, some of which are preserved. We have also extant three books against Autolytus, a learned heathen, in which he displays great learning, and from which it appears that he had once been a heathen. These works afford, as it is said, the earliest example of the use of the term "Trinity," applied by the author to the three persons of the Godhead. Some have supposed that he approaches to Arianism, when

he asserts that the Word may exist in *place*, and that he was begotten in *time*. Theophilus's books to Autolytus were published in Latin by Conrad Gefner at Zurich, in 1546, and were inserted in the "Orthodoxographia," Basil, 1555. They were annexed in Gr. and Lat. to the Supplement of the "Bibliotheca Patrum," 1624; and were printed at the end of St. Justin's Works by Morellus. Lardner.

THEOPHILUS, bishop or patriarch of Alexandria, of violent and turbulent disposition, was ordained to that see in 385. He gained reputation and influence by his zeal in destroying the temple of Serapis, and other pagan temples of Egypt in 389. (See THEODOSIUS.) He was, under the guise of a friend, a secret enemy to John Chrysostom, after he had been ordained to the see of Constantinople in 397. Without much real regard for religion, he was the zealous champion of orthodoxy; and having called a council at Alexandria in 399, he prevailed with the assembly to condemn all the followers of Origen, and with the assistance of a band of soldiers, compelled them to abandon their residence on mount Nitria. The poor monks, failing to find a secure refuge, repaired to Constantinople, to lay their complaints before the emperor. The humanity of John Chrysostom irritated Theophilus, who was employed by the empress Eudoxia, for prosecuting her revenge against Chrysostom. Accordingly, he arrived at Constantinople at the head of a body of Egyptian sailors and dependent bishops, avowing that he was going to depose John. His purpose was executed at the synod of Chalcedon in 403. (See CHRYSOSTOM.) His malignity pursued this venerable prelate in his exile, by a libel filled with abusive expressions, which was translated at his request by Jerom, from Greek into Latin. Theophilus died at Alexandria in 412. The most considerable of his works was a large treatise against Origen. Some of his epistles are found among those of Jerom, and some of his canonical epistles are contained in the collections of Zonaras and Balsamon. Of this prelate Dupin has given the following character: "There is nothing in the writings of Theophilus that can turn to his commendation; they are obscure, unintelligible, and full of false and impertinent reasonings and reflections. He was a good politician, but a bad author. He knew better how to manage a court intrigue, than to resolve a question in divinity. The only rule for his opinions was his interest or his ambition. He was ready to embrace any opinion or party that suited his purpose, without examining whether it was just or reasonable." Dupin. Lardner. Gibbon.

THEOPHRASTA, in *Botany*, so called in memory of the father of all natural historians, Theophrastus, native of Eresos in the isle of Lesbos; whence Plumier named this genus *ERESIA*. (See that article.) Linnæus on such occasions always preferred the appellation by which the person intended to be celebrated was best known.—Linn. Gen. 84. Schreb. 110. Willd. Sp. Pl. v. 1. 824. Mart. Mill. Dict. v. 4. Swartz Obs. 58. Juss. 150. Lamarck Illustr. t. 119. (Eresia; Plum. Gen. 8. t. 25.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Apocineis affine*, Juss.

Gen. Ch. *Cal.* Perianth inferior, small, of one leaf, in five deep, obtuse, permanent segments. *Cor.* of one petal, bell-shaped, spreading, cut more than half way down into five rounded equal segments. "Nectary five small, ovate, obtuse glands, thickest at the point, lying upon the segments of the corolla." *Jacq.*—*Stam.* Filaments five, thread-shaped, united below to an internal membrane, so as to form a short, thick, furrowed column, crowned with a five-rayed horizontal disk; anthers five, of two separate oblong lobes,

lobes, attached to the sides of each segment of the disk, underneath. *Pist.* Germen superior, ovate; style cylindrical, the length of the stamens, erect; stigma in five obtuse lobes. *Peric.* Berry globose, coated, of one cell. *Seeds* several, roundish, somewhat compressed.

Ess. Ch. Corolla bell-shaped, in five obtuse spreading segments, with a nectary of five incumbent glands. Berry coated, of one cell, with several seeds.

1. *Th. americana.* Large-fruited Theophrasta. Linn. Sp. Pl. 212. Willd. n. 1. Swartz Obf. 59. (*Erefia foliis aquifolii longifimis*; Plum. Ic. 119. t. 126.)—Leaves obtuse. Clusters terminal, erect.—Native of barren dry bushy shady places in Hispaniola. *Swartz.* Stem shrubby, one or two feet high, erect, simple, leafy in its upper half, round, thorny, clothed with rusty down. *Leaves* opposite or whorled, on very short stalks, erect, oblong-lanceolate, obtuse, tapering at the base, very rigid, ferrated; their serratures alternately inflexed and reflexed, each tipped with a small, prominent, rigid, black-pointed spine. *Footstalks* thick, rufous, closely pressed to the stem. *Clusters* short, terminal, from the midst of the terminal leaves, many-flowered, partial *flower-stalks* numerous, short, curved, single-flowered. *Fruit* two inches in diameter, yellow, brittle, often for the most part hollow or empty, its *receptacle* juicy at the bottom. *Seeds* black, hard, attached by their base. *Swartz.* We presume the *clusters*, from Plumier's figure, to be erect, and the *seeds* numerous.

2. *Th. longifolia.* Small-fruited Theophrasta. Jacq. Coll. v. 4. 136. Hort. Schoenbr. v. 1. 62. t. 116. Willd. n. 2.—Leaves acute. Clusters lateral, drooping.—Native of the Caraccas. It flowered in the stove at Schoenbrun from August till November. The *stem* is said to be twenty feet high, but always unbranched. *Leaves* imperfectly whorled, near two feet long, reclining, with spinous serratures, smooth, of a dark shining green, with numerous transverse veins from the mid-rib. *Clusters* numerous, scattered between the whorls of leaves, stalked, drooping, a span long, of numerous little orange-coloured or scarlet *flowers.* *Fruit* in its native country about an inch in diameter, with about four *seeds*; but in the garden it did not attain more than half that size, and perfected only one. If there be no mistake in Dr. Swartz's description of the first species, there is a prodigious difference between the stature of the two. Yet we have a suspicion, that they may possibly not be more than varieties of each other. As to the generic character, Plumier's representation of the parts of the *flower* is too imperfect for us to suppose him more right than the faithful Jacquin. Swartz's description may easily be reconciled with the *Hortus Schoenbrunensis.*

THEOPHRASTICS, a name given to the followers of Paracelsus, from his name Theophrastus.

THEOPHRASTUS, in *Biography*, a distinguished Greek philosopher, the favourite pupil of Aristotle, and nominated by him as his successor in the school of the Lyceum, was born at Eresium, a maritime town of Lesbos, in the second year of the 102d Olympiad, B.C. 371. His first rudiments of education were received under Alcippus in his own country, and being sent by his father to Athens, he became first a disciple of Plato and afterwards of Aristotle. Such were his natural talents, that, under such tuition, he made great progress both in philosophy and eloquence: so that his original name, Tyrctamus, was changed, either by his master or his followers, into Theophrastus. After he undertook the Peripatetic school in the year B.C. 323, his reputation was so distinguished, that the number of his scholars was about 2000. His erudition and engaging manners recommended him to the notice of Cassander and

Ptolemy: by the former he was invited to Macedon, and by the latter to Egypt; and among the Athenians he was so great a favourite, that, when he was accused by one of his enemies of teaching impious doctrines, the accuser could not without difficulty escape the punishment which he endeavoured to bring upon Theophrastus. Theophrastus is no less highly celebrated for his generosity and public spirit, than for his industry, learning, and eloquence. He is said to have twice saved his country from the oppression of tyrants; and he contributed liberally towards defraying the expence of public meetings held by philosophers for learned and ingenious conversation. In the public schools he appeared, after the manner of Aristotle, in an elegant dress, and was very attentive to the graces of elocution: and hence it is said he obtained the appellation of Theophrastus, the divine speaker. Towards the close of life, which was prolonged to the age of 85 years, he became very infirm, and was conveyed to the school in a carriage. In contemplating the shortness of life, he expressed great regret; complaining that long life was granted to stags and crows, to whom it was of little value, but was denied to man, who, if it were of longer duration, might attain the summit of science: whereas now, as soon as he arrives within sight of it, he is taken away. His last advice to his disciples was, that since it is the lot of man to die as soon as he begins to live, they should take greater pains to enjoy life as it passes, than to acquire posthumous fame. A large body of Athenians attended his funeral.

The works of Theophrastus comprehended a variety of subjects, and were numerous. His doctrine differed in some respects from that of his master Aristotle. He taught that the predicaments, or categories, were as numerous as the motions and changes to which beings are liable; and that among motions, or changes, are to be reckoned desires, appetites, judgments and thoughts. He maintained, that all things are not produced from contraries; but some from contraries, some from similar causes, and some from simple energy; that motion is not to be distinguished from action; and that there is one divine principle of all things, by which all things subsist. By this divine principle, it is thought that Theophrastus meant the First Mover, without whom other things could not be moved, and therefore could not subsist. Of his moral maxims, the following are the most worthy of notice. "Respect yourself, and you will never have reason to be ashamed before others. Love is the passion of an indolent mind. Blushing is the complexion of virtue. Time is the most precious expenditure."

Few of his works, of which Diogenes Laertius enumerates more than 200, have reached our time: of these, the most famous is entitled "Characters," describing different moral classes of men, such as the flatterer, the impudent, the discontented, the garrulous, the superstitious, &c.; so distinguished and described, as to shew great knowledge of mankind. Of his other works on natural history, the principal are his "History of Plants," in nine books, which Haller has particularly recommended to the notice of botanical students; "On the Causes of Plants," relating chiefly to the natural and artificial means of bringing them to maturity; to agriculture and horticulture; to the tastes and odours of vegetables; "On Stones;" "On Winds;" "On Fire;" "On Honey;" "On the Signs of Fair Weather, and of Tempests and Rain;" "On Animals which change their Colour;" "On Animals which are born suddenly;" "On Fish which live out of Water." Theophrastus ranks amongst the most distinguished of the ancients for comprehensive genius and diligent enquiry into nature. The last edition of the whole extant works of Theophrastus is that

of Dan. Heinsius, Greek and Latin, fol. Lugd. Bat. 1613. Of his history of plants, the most complete is that of Budæus, Greek and Latin, fol. Amst. 1644. Among the most esteemed editions of his "Characters," which are numerous, we may reckon those of H. Casaubon, of Needham, with the notes of Duport, Cantab. 1712, and of J. Fr. Fischer, Coburg. 1763. Diog. Laert. Brucker by Enfield. Haller Bib. Bot.

THEOPHYLACT, named *Simocatta*, a Greek historian, a native of Greece, but of Egyptian origin, flourished about A.D. 612. His history of the reign of the emperor Maurice is comprehended in eight books, and terminates with the massacre of this prince and his children by Phocas. Casaubon reckons Simocatta one of the best of the later Greek historians. The work just mentioned was printed at the Louvre, in 1647, fol. and forms a part of the Byzantine historians. An edition of his "Epistles, Moral, Rural, and Amatory," was given by Aldus. His "Physical Problems" were published first by Vulcanius at Leyden, and afterwards by Andrew Schottus. His "History of the Habitable World" is cited by Eustathius, in his Commentary on the Periegesis of Dionysius. Gen. Biog.

THEOPHYLACT, archbishop of Acris, the capital of Bulgaria, was a native of Constantinople, and flourished under the emperors Michael Ducas, Nicephorus Botoniates, and Alexis Comnenus. After his elevation to the archbishopric of Acris, by the persuasion of the wife of Ducas, he diligently laboured in propagating the Christian faith, and composed several works, which give him rank among the principal ecclesiastical writers of his age. The time of his death is not known; but he was living in 1071. His "Commentaries on the Four Gospels, the Acts of the Apostles, and the Epistles of St. Paul," which are his chief work, are for the most part abridged from Chrysostom and others. He also wrote "Commentaries on the Minor Prophets." Several editions of his Commentaries have been published in Greek and Latin, and also in Latin only. "Seventy-five Epistles" of this author were published by Meursius, in Greek, in 1617, and a Latin translation in 1622. Some other tracts have been attributed to this author. Dupin says, that the Commentaries of Theophylact are very useful for the literal explanation of the Scriptures: and Lardner observes, that he quotes no forged writings or apocryphal books of the New Testament, many of which he excludes by his observation on John, i. 31—34. that Christ wrought no miracle in his infancy, or before the time of his public ministry. Dupin. Lardner.

THEOPNEUSTÆ, Θεοπνεύσταί, formed of Θεός, *God*, and πνεύω, *I breathe*, an epithet given to enthusiastical diviners.

THEOPOLIS, in *Ancient Geography*, a town of Gallia Narbonensis, belonging to the Aventici, N.E. of Forum Novum.

THEOPROPRIA, Θεοπροπρία, formed of Θεός, *God*, and προπρία, *I excel*, a designation given to oracles. See ORACLE.

THEOPSIA, Θεοψία, formed of Θεός, *God*, and οψομαι, *I see*, in *Mythology*, denoted the appearance of gods. Cicero, Plutarch, Arnobius, and Chrysostom, mention appearances of this kind.

THEORBO, Τηορβα, or Τιορβα, a musical instrument, made in form of a large lute; except that it has two necks, or jugs, the second and longer of which sustains the four last rows of chords, which are to give the deepest sounds. See LUTE.

The word is formed from the French *teorbe*, or *theorbe*,

and that from the Italian *tiorbe*, which signifies the same, and which some will have to be the name of the inventor.

The theorbo is an instrument which for many years succeeded to the lute, in the playing of thorough basses; it is said by some to have been invented in France, by the sieur Hotteman, and thence introduced into Italy, &c.

The only difference between the theorbo and the lute is, that the former has eight bass or thick strings twice as long as those of the lute; which excess of length renders their sound so exceedingly soft, and keeps it up so long a time, that it is no wonder many prefer it to the harpsichord itself. At least it has this advantage over it, that it is easily removed from place to place, &c.

All its strings are usually single; though there are some who double the bass-strings with a little octave, or the small strings with an unison; in which case, bearing more resemblance to the lute than the common theorbo, the Italians call it the *arcileuto*, or arch-lute.

THEOREM, in the *Mathematical Method*, a proposition which terminates in theory, and which considers the properties of things already made or done.

Or, a theorem is a speculative proposition, deduced from several definitions compared together. Thus, if a triangle be compared with a parallelogram standing on the same base, and of the same altitude, and partly from their immediate definitions, and partly from other of their properties already determined, it is inferred, that the parallelogram is double the triangle: that proposition is the theorem.

Theorem stands contradistinguished from *problem*.

There are two things to be chiefly regarded in every theorem, *viz.* the proposition and the demonstration: in the first is expressed what agrees to some certain thing under certain conditions, and what does not.

In the latter, the reasons are laid down, by which the understanding comes to conceive, that it does or does not agree to them.

Theorems are of various kinds: as,

THEOREM, Universal, is that which extends to any quantity without restriction, universally. As this, that the rectangle of the sum and difference of any two quantities is equal to the difference of their squares.

THEOREM, Particular, is that which extends only to a particular quantity. As this: in an equilateral right-lined triangle, each of the angles is sixty degrees.

THEOREM, Negative, is that which expresses the impossibility of any assertion. As, that the sum of two biquadrate numbers cannot make a square number.

THEOREM, Local, is that which relates to a surface. As, that triangles of the same base and altitude are equal.

THEOREM, Plane, is that which either relates to a rectilinear surface, or to one terminated by the circumference of a circle. As, that all angles in the same segment of a circle are equal.

THEOREM, Solid, is that which considers a space terminated by a solid; that is, by any of the three conic sections. *E. gr.* this: that if a right line cut two asymptotic parabolas, its two parts terminated by them shall be equal. See SOLID.

THEOREM, Reciprocal, is one whose converse is true. As, that if a triangle have two equal sides, it must have two equal angles: the converse of which is likewise true, that if it have two equal angles, it must have two equal sides.

THEOREM, in *Algebra* and *Analysis*, is sometimes used to denote a rule, particularly when that rule is expressed in symbols or formulae, of which there is of course a great number; but of these, some few, either from their importance,

THEOREM.

portance, curiosity, or other considerations, have retained particular denominations, under which they are frequently referred to by modern authors: it is therefore necessary to have them so classed, that a reader may be able to ascertain the principles on which they are founded, the purposes they are intended to answer, and the cases to which they will best apply. The theorems to which we here allude, are Bernoulli's theorem, the Binomial theorem, Cotes's, Taylor's, Maclaurin's, &c.

Bernoulli's Theorem, is a general formula for the development of any fluent or integral, of any proposed fluxion or differential; which may be stated as follows: viz. X being any function of x,

$$\int X dx = X \frac{x}{1} - \frac{dX}{dx} \cdot \frac{x^2}{1 \cdot 2} + \frac{d^2X}{dx^2} \cdot \frac{x^3}{1 \cdot 2 \cdot 3} - \frac{d^3X}{dx^3} \cdot \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4}, \&c.$$

Let us denote by Y, the value of this integral when $x = 0$, $X, \frac{dX}{dx}, \frac{d^2X}{dx^2}, \&c.$ being also denoted by $Y', Y'', Y''', \&c.$ and we shall have generally,

$$\int X dx = Y + Y' \frac{x}{1} + Y'' \frac{x^2}{1 \cdot 2} + Y''' \frac{x^3}{1 \cdot 2 \cdot 3} + \&c.$$

Now, in order to pass from the general value of $\int X dx$, which we shall represent by y , to that which answers to the case of $x = 0$, it is evident that we must in Taylor's formula make $h = -x$, which gives

$$Y = y - \frac{dy}{dx} \cdot \frac{x}{1} + \frac{d^2y}{dx^2} \cdot \frac{x^2}{1 \cdot 2} - \frac{d^3y}{dx^3} \cdot \frac{x^3}{1 \cdot 2 \cdot 3} + \&c.$$

Substituting in this equation, in the place of $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$

their respective values, and taking that of $\int X dx$, we shall have

$$\int X dx = Y + X \cdot \frac{x}{1} - \frac{dX}{dx} \cdot \frac{x^2}{1 \cdot 2} + \frac{d^2X}{dx^2} \cdot \frac{x^3}{1 \cdot 2 \cdot 3} - \&c.$$

the quantity Y being still a constant arbitrary. By integrating, we arrive also at this development: thus, if we decompose the differential X dx into its two factors X and dx, and integrate the second, we shall have

$$\int X dx = Xx - \int x dX.$$

But

$$\int x dX = \int \frac{dX}{dx} \cdot x dx = \frac{1}{2} x^2 \frac{dX}{dx} - \frac{1}{2} \int x^2 \frac{d^2X}{dx^2}$$

$$\int x^2 \frac{d^2X}{dx^2} = \int \frac{d^2X}{dx^2} \cdot x^2 dx = \frac{1}{3} x^3 \frac{d^2X}{dx^2} - \frac{2}{3} \int x^3 \frac{d^3X}{dx^3}$$

$$\int x^3 \frac{d^3X}{dx^3} = \int \frac{d^3X}{dx^3} \cdot x^3 dx = \frac{1}{4} x^4 \frac{d^3X}{dx^3} - \frac{3}{4} \int x^4 \frac{d^4X}{dx^4}$$

&c. &c. &c.

And putting successively for $\int x dX, \int x^2 \frac{d^2X}{dx^2}, \&c.$ their respective values, there results,

$$\int X dx = X \frac{x}{1} - \frac{dX}{dx} \cdot \frac{x^2}{1 \cdot 2} + \frac{d^2X}{dx^2} \cdot \frac{x^3}{1 \cdot 2 \cdot 3} - \&c.$$

which is the theorem of John Bernoulli, and is the same with regard to the integral calculus, as that of Taylor to the differential.

Binomial Theorem, or Newtonian theorem, is a general formula for the development of any binomial of the form $(a + x)^n$; viz.

$$(a + x)^n = a^n \times \left\{ 1 + \frac{n}{1} \left(\frac{x}{a}\right) + \frac{n}{2} \cdot \frac{n-1}{2n} \left(\frac{x}{a}\right)^2 + \frac{n}{3} \cdot \frac{n-1}{2n} \cdot \frac{n-2}{3n} \left(\frac{x}{a}\right)^3 + \&c. \right\}$$

See BINOMIAL Theorem.

Briggs's Theorem.—There are more than one formula that have received this designation, but we believe that the following is generally understood to be implied; viz.

“The n th differences of any consecutive n th powers, or of any n th powers whose roots are in arithmetical progression, are expressed by the formula

$$n(n-1)(n-2)(n-3)(n-4) \dots 1 \cdot d^n$$

d being the common difference of the roots.”

The demonstration of this theorem is commonly made to depend upon principles drawn from the fluxional analysis; but we prefer giving a sketch of that which appeared in vol. xi. of the Irish Transactions by Mr. Burk, being deduced from the most elementary considerations.

We know that the expansion of $(p + x)^n$, is of the form

$$p^n + nx p^{n-1} + Cx^2 p^{n-2} + Dx^3 p^{n-3} + \&c.$$

Let $o, p, q, r, s, \&c.$ be the terms of any decreasing arithmetical progression, of which the difference is d ; then since $o = p + d, p = q + d, \&c.$ we have

$$o^n = (p + d)^n = p^n + nd p^{n-1} + C d^2 p^{n-2} + \&c.$$

$$p^n = (q + d)^n = q^n + nd q^{n-1} + C d^2 q^{n-2} + \&c.$$

$$q^n = (r + d)^n = r^n + nd r^{n-1} + C d^2 r^{n-2} + \&c.$$

Taking the first, second, third, &c. differences, we have

First Differences

$$nd p^{n-1} + C d^2 p^{n-2} + \&c.$$

$$nd q^{n-1} + C d^2 q^{n-2} + \&c.$$

$$nd r^{n-1} + C d^2 r^{n-2} + \&c.$$

And since $p^{n-1} = (q + d)^{n-1} = q^{n-1} + (n-1)d q^{n-2} + \&c.$ we have for the

Second Differences

$$nd(n-1)d q^{n-2} + \&c.$$

$$nd(n-1)d r^{n-2} + \&c.$$

$$nd(n-1)d s^{n-2} + \&c.$$

Third Differences

$$nd(n-1)d(n-2)d r^{n-3} + \&c.$$

$$nd(n-1)d(n-2)d s^{n-3} + \&c.$$

Fourth Differences

$$nd(n-1)d(n-2)d(n-3)d r^{n-4} + \&c.$$

Whence, by an infallible and obvious deduction,

n th Differences

$$nd(n-1)d(n-2) \dots (n-n+1) d \omega^{n-n}$$

$(n+1)$ th Differences

$$nd(n-1)d(n-2) \dots (n-n) d \omega^{-1}.$$

THEOREM.

But since $n - n = 0$, the $(n + 1)$ th differences $= 0$; and since $w^{n-n} = w^0 = 1$, the n th differences become

$$n(n-1)(n-2)(n-3) \dots 3 \cdot 2 \cdot 1 d^n$$

It may not be amiss to observe, that we have only employed the first term of the several orders of differences, which however is sufficient for our purpose, since it is obvious that the n th difference can have but one term; for the development of $(p + d)^n$ gives $n + 1$ terms; and since one term vanishes with every difference, the first difference will have n terms, the second $n - 1$, the third $n - 2$, &c.; and consequently the n th difference will have $n - (n - 1) = 1$ term only. See Irish Transactions, vol. xi. or Monthly Review, vol. lxxiv.

Cotes's Theorem, or Cotesian Theorem.—The geometrical properties of this very interesting theorem are explained under the article *COTESIAN Theorem*; it will only be necessary therefore in this place to state the same analytically. In this case, the general enunciation is:

"All the imaginary roots of the binomial equation $x^n - 1 = 0$, are contained in the general formula $x^2 - 2 \cos \frac{2k\pi}{n} x + 1 = 0$; and those of $x^n + 1 = 0$, in the formula $x^2 - 2 \cos \frac{(2k+1)\pi}{n} x + 1 = 0$, k being any integer not divisible by n , and π representing the semi-circumference." See *RECIPROCAL Equations*.

Euler's Theorem is used to denote the theorem or formula first given by this author, for ascertaining the direct integrability of differential equations, which is as follows. The equation being reduced to the form

$$M dx + N dy = 0,$$

where M and N are functions of x and y ; if $\frac{M}{dy} = \frac{N}{dx}$, then

the integration may be obtained by a direct process; but if this equality have not place, the integration can then only be effected by indirect means, which frequently involve considerable difficulty.

Fermat's Theorem.—There are several theorems in the theory of numbers which are due to this ingenious analyst; but that which is more particularly designed by Fermat's theorem is this; *viz.* "Neither the sum nor difference of any two integral powers, above the square, can be equal to a rational power of the same dimension;" or, which is the same, the equation

$$x^n \pm y^n = z^n$$

is always impossible in rational numbers, if n be greater than 2.

The cases of $n = 3$ and $n = 4$ have been demonstrated; but notwithstanding the numerous attempts of the most celebrated analysts of the last and of the present age, the case of $n = 5$, and all the succeeding values of n , remain without demonstration; and as this is now the only theorem of this author which has not submitted to the power of the modern analysis, the National Institute of France has made it the subject of the prize of 3000 francs, to be decided by 1818.

Under the article *NUMBERS*, amongst the miscellaneous propositions, we have mentioned another theorem of Fermat's, which had not then been demonstrated, but which has since been effected by M. Cauchy, corresponding member of the Institute. The reader will also find some farther remarks relative to the equation $x^n \pm y^n = z^n$, under our article *POWER*.

Gauss's Theorem is used to denote a theorem invented by this distinguished mathematician, for the solution of certain binomial equations. We have seen, in the article *RECIPROCAL Equations*, in what manner the roots of binomial equations may be obtained by means of a table of sines and cosines; but Gauss's theorem is the converse of this, and shews in what manner the sines and cosines of certain angles may be obtained, by the numerical solution of such equations. See *POLYGON*.

Guldin's Theorem is the same as the *CENTROBARYC Method*; which see.

Lagrange's Theorem is commonly used to denote the general formula assumed by Lagrange as the foundation of his theory of functions; which may be thus enunciated.

"If ϕx be any function whatever of a variable quantity x , and if x changes its value, and becomes $x + i$, then the $\phi(x + i)$ may be represented or resolved into a series of the form

$$\phi(x + i) = \phi x + P i + Q i^2 + R i^3 + \&c.$$

in which the co-efficients of the powers of i are new functions of x , derived from the primitive function ϕx , independent of i ; and, moreover, that every co-efficient is derived from the preceding one, in the same manner as the first is derived from the original function." See *FUNCTIONS*.

Leibnitz's Theorem is a theorem proposed by this author for differencing under the sign \int , and it may be exhibited under the form $\frac{d f M dx}{dy} = \int \frac{d M}{dy} dx$, where $M = \frac{du}{dx}$, u being any function of x and y .

Since $\frac{du}{dx dy} = \frac{du}{dy dx}$ by the known principles of the differential calculus; if we make $u = \int M dx$, we shall have $\frac{du}{dx} = M$, $\frac{d^2 u}{dx dy} = \frac{d M}{dy}$; and integrating with regard to x , we shall find

$$\int \frac{d^2 u}{dx dy} dx = \int \frac{d^2 u}{dy dx} dx = \frac{du}{dy} = \int \frac{d M}{dy} dx.$$

This is called by Leibnitz *differentiatio de curva in curvam*, because in the question which he proposed to resolve, he passed from one curve to another of the same species, by making one of the constant quantities variable. See *LA CROIX* "Calculus Integral."

Maclaurin's Theorem is a formula which we owe to this author for expressing any function y , of a variable quantity x ; *viz.* adopting the differential notation,

$$y = (y) + \left(\frac{dy}{dx}\right) x + \frac{1}{2} \left(\frac{d^2 y}{dx^2}\right) x^2 + \frac{1}{2 \cdot 3} \left(\frac{d^3 y}{dx^3}\right) x^3 + \&c.$$

where (y) , $\left(\frac{dy}{dx}\right)$, $\left(\frac{d^2 y}{dx^2}\right)$, &c. represent what these several quantities become when $x = 0$.

Let $y = A + Bx + Cx^2 + Dx^3 + \&c.$ differencing, and dividing by dx , we have

$$\frac{dy}{dx} = B + 2Cx + 3Dx^2 + \&c.$$

$$\frac{d^2 y}{dx^2} = 2C + 2 \cdot 3 Dx + \&c.$$

$$\frac{d^3 y}{dx^3} = 2 \cdot 3 D + \&c.$$

confe-

THEOREM.

consequently, when x in each of these = 0, we have

$$(y) = A, \left(\frac{dy}{dx}\right) = B; \left(\frac{d^2y}{2 \cdot dx^2}\right) = C; \frac{1 d^3y}{2 \cdot 3 dx^3} = D;$$

therefore,

$$y = (y) + \left(\frac{dy}{dx}\right)x + \frac{1}{2} \left(\frac{d^2y}{dx^2}\right)x^2 + \frac{1}{2 \cdot 3} \left(\frac{d^3y}{dx^3}\right)x^3 + \&c.$$

See Maclaurin's "Fluxions," and Boucharlat's "Calcul Differential, &c."

Moirre's Theorem. See the next article.

Multinomial Theorem, sometimes called *Moirre's theorem*, having been first discovered by that author, is a general expression or formula for determining any power or root of a given quantity consisting of any number of terms. This theorem was first published by its author in N^o 230. of the Phil. Transf. 1697; but it was afterwards simplified by Euler in his "Calcul Differential," and the same has also been done by Arbogast in his "Calcul des Derivations."

The general form of this theorem, as given in Bonycastle's Algebra, is as follows:

$$\left(A_0 + \frac{A_1}{1}x + \frac{A_2}{2}x^2 + \frac{A_3}{3}x^3 + \dots + \frac{A_n}{n}x^n \right)^m = A^m +$$

$$\left. \begin{aligned} & m \frac{A_1}{1} B \cdot \frac{x}{A} + \frac{2m}{2} \frac{A_2}{2} B \left. \begin{aligned} & + (m-1) \frac{A_1}{1} \frac{A_1}{1} B \right\} \frac{x^2}{2 A} + \frac{3m}{3} \frac{A_3}{3} B \left. \begin{aligned} & + (2m-1) \frac{A_2}{2} \frac{A_1}{1} B \right\} \frac{x^3}{3 A} + \frac{4m}{4} \frac{A_4}{4} B \left. \begin{aligned} & + (3m-1) \frac{A_3}{3} \frac{A_1}{1} B \right\} \frac{x^4}{4 A} + \&c. \\ & + (m-2) \frac{A_2}{2} \frac{A_2}{2} B \left. \begin{aligned} & + (m-3) \frac{A_1}{1} \frac{A_1}{1} \frac{A_1}{1} B \right\} \end{aligned} \right\}$$

Where $B = A^m$, and $B, B, B, \&c.$ are the co-efficients of the terms immediately preceding those in which they first appear; and the manner of applying this theorem to any particular case, is by substituting the numbers or letters in the given example for $A, A, A, \&c.$ and the numerical value of m for m . It would lead us too far to attempt the demonstration of this theorem in this place, we must, therefore, refer the reader for such information to the works above-mentioned.

Newtonian Theorem. See *BINOMIAL Theorem*.

Taylor's Theorem, an elegant and highly valuable formula, which was first published by Dr. Brook Taylor in his "Methodus Incrementorum," which is as follows; viz.

"If Y represent any function whatever of the variable quantity x , and if x be increased by any difference Δx , the value of Y , viz. $Y + \Delta Y$, becomes (employing the differential notation)

$$Y + \Delta Y = Y + \frac{\Delta x dY}{1 \cdot dx} + \frac{\Delta x^2 d^2Y}{1 \cdot 2 \cdot dx^2} + \frac{\Delta x^3 d^3Y}{1 \cdot 2 \cdot 3 dx^3} + \&c.$$

$$\text{or } \Delta Y = \frac{\Delta x dY}{1 \cdot dx} + \frac{\Delta x^2 d^2Y}{1 \cdot 2 \cdot dx^2} + \frac{\Delta x^3 d^3Y}{1 \cdot 2 \cdot 3 dx^3} + \&c.$$

The demonstration of this celebrated theorem is given very concisely by La Croix, on the following principles.

Let Y be any function of x , and let Y' denote what this function becomes, when x becomes $x + b$, we may write

$$Y' = A + Bb + Cb^2 + Db^3 + \&c.$$

in which development, it is obvious that $A, B, C, \&c.$ are functions of x .

If now we difference this equation with b variable and x constant, we obtain, dividing by db ,

$$\frac{Y'}{db} = B + 2Cb + 3Db^2 + \&c.$$

Again, differencing with x variable and b constant, we have

$$\frac{Y'}{dx} = \frac{dA}{dx} + \frac{dB}{dx}b + \frac{dC}{dx}b^2 + \frac{dD}{dx}b^3 + \&c.$$

But as x and b enter exactly in the same manner, it follows

that $\frac{Y'}{dx} = \frac{Y'}{db}$, whence the first of these series is equal to the

second; equating, therefore, the co-efficients of the like powers of b , we have

$$B = \frac{dA}{dx}, C = \frac{dB}{2 dx}, D = \frac{dC}{3 dx}, \&c.$$

Now

$$A = Y, B = \frac{dY}{dx}, C = \frac{d^2Y}{1 \cdot 2 \cdot dx^2}, D = \frac{d^3Y}{1 \cdot 2 \cdot 3 dx^3};$$

whence

$$Y' = Y + \frac{dY}{1 \cdot dx} b + \frac{d^2Y}{1 \cdot 2 \cdot dx^2} b^2 + \frac{d^3Y}{1 \cdot 2 \cdot 3 dx^3} b^3 + \&c.$$

Or writing

$$Y' = Y + \Delta Y, \text{ and } x + b = x + \Delta x,$$

we have

$$\Delta Y := \frac{\Delta x dY}{1 \cdot dx} + \frac{\Delta x^2 d^2Y}{1 \cdot 2 \cdot dx^2} + \frac{\Delta x^3 d^3Y}{1 \cdot 2 \cdot 3 dx^3} + \&c.$$

See La Croix "Calcul Differential," p. 21.

Trinomial Theorem is only a particular case of the *Multinomial Theorem*, which see.

Wilson's Theorem is a curious formula relative to prime numbers, published first by Waring in his "Meditationes Algebrae," which is as follows.

"If n be any prime number, then will

$$1 \cdot 2 \cdot 3 \cdot 4, \&c. (n-1) + 1$$

be divisible by n ."

This curious theorem was not demonstrated by sir John Wilson, who first discovered it, nor by Waring, by whom it was first made public; it has, however, since received different demonstrations from Lagrange, Gauss, &c. the latter of which is very simple, and has been adopted by Barlow in his "Theory of Numbers," to which work we beg to refer our readers, as it would require more room than we can allow ourselves to give it at full length in this place.

The above include, we believe, all those theorems which are known by any particular designation; there are, doubtless, many others equally important, and which are equally entitled to bear the names of their respective authors, but custom has not sanctioned the adoption; and we have, therefore, not introduced them.

THEO-

THEORETIC, THEORETICAL, or *Theoric*, formed from *θεωρω*, *I see* or *contemplate*, something relating to theory, or that terminates in speculation. In which sense it stands opposed to *practical*.

The sciences are ordinarily divided into *theoretical*, as theology, philosophy, &c.; and *practical*, as medicine, law, &c. See SCIENCE.

THEORETIC, Theoreticus, is an appellation peculiarly given to an ancient sect of physicians, contradistinguished by it from the empirics. See EMPIRIC.

Theoretic physicians were such as applied themselves to a careful study and consideration of what relates to health and diseases; the principles of the human body, and its structure and parts; with their actions and uses; whatever befalls it, either naturally or preternaturally; the differences of diseases, their nature, causes, signs, indications, &c.; the textures, properties, &c. of plants, and other medicines, &c. In a word, the theoretic physicians were such as proceeded in their judgment and practice on the foot of reason, in opposition to the empirical physicians, who proceeded wholly on experience. See MEDICINE.

THEORETICAL Arithmetic and Philosophy. See the substantives.

THEORI, *θεορειν*, in *Antiquity*, an appellation given to those Athenians who performed the solemnity called *theoria*.

THEORIA, *θεωρειν*, a solemn annual voyage to Apollo's temple, in the island of Delos, performed by the Athenians always in the same ship in which Theseus went. For the particularities of this naval procession, see Potter Archæol. Græc. lib. ii. cap. 9. tom. i. p. 284, seq.

THEORIC MONEY, in *Ancient Authors*, was what was raised, by way of tax on the people, to defray the expences of theatrical representations, and other spectacles.

There were particular questors and treasurers of the theoric money. By a law of Eubulus, it was made a capital crime to pervert the theoric money to any other use; even to employ it in the occasions of war.

THEORICAL ASTRONOMY, is that part of astronomy which considers the true structure and disposition of the heavens, and heavenly bodies; and accounts for their various phenomena therefrom. See ASTRONOMY.

It is thus called, in opposition to that part which considers their apparent structure, or their disposition as viewed by the eye, which is called *spherical astronomy*.

The several parts of theoretical astronomy, see under SYSTEM, SUN, STAR, PLANET, EARTH, MOON, SATELLITE, and COMET.

THEORY, a doctrine which terminates in the sole speculation, or consideration, of its object, without any view to the practice or application of it.

To be learned in an art, &c. the theory suffices; to be a master of it, both the theory and practice are required. Machines, many times, promise very well in the theory, yet fail in the practice.

We say, theory of the moon, theory of the rainbow, of the microscope, the camera obscura, the motion of the heart, the operation of purgatives, &c.

THEORIES of the Planets, &c. are systems or hypotheses, according to which the astronomers explain the reasons of the phenomena or appearances of them. See SYSTEM.

THEORY, in *Music*, in the hands of a mere mathematician is confined only to ratios and the philosophy of sound. (See HARMONICS.) But among *practical musicians*, the theory of harmony or composition is connected with the combination of agreeable sounds, and the practice and performance of real music.

THEORY, Atomic, in *Chemistry*, the means of explaining

the composition and decomposition of chemical bodies, by considering their ultimate atoms or particles as peculiar and distinct elementary solids, never changing in their figure, weight, or volume, under any circumstances.

It would be difficult to conceive the existence of any compound, without supposing it to have originated by union, in some way or other, of particles of its elementary constituents: but the prevalence of a doctrine, which has been generally advanced by mathematicians, *viz.* the infinite divisibility of matter, has never allowed philosophers to conclude that the circumstance of compounds being made up of particles, must necessarily limit the proportions in which the elements combine. If the elementary bodies be conceived infinitely divisible, the molecules, or compound particles, may be conceived infinitely small, and the number of mean compounds existing between any two given extremes may be also considered infinite.

If such were the nature of elementary matter, and no other causes interfered, there could be no limitation to the proportions in which simple matter would combine. This, however, is contrary to fact; as it is a fact known from the earliest dawnings of chemical knowledge, that bodies are limited in the proportions of their elements; the most striking of these facts being the mutual saturation which takes place between an acid and an alkali, and the uniform proportions afforded in the analysis of many native compounds.

Philosophers were always satisfied to consider this fact of the limitation of the proportions of bodies as one of the hidden secrets of nature, as difficult to conceive as the nature of the attraction by which their elements were held together. Berthollet appears to have been the first to attempt this arduous task, in his ingenious work, entitled "Chemical Statics." He supposes that the particles of bodies, when brought within the sphere of attraction, combine without controul till the compound assumes some definite form, by which it is withdrawn from the situation in which it was formed. He supposes the chemical affinity of bodies to be distinct from that power on which their cohesion depends, and also that power by which they tend to an elastic state.

Hence he concludes, that every solid compound is determined by the cohesion which takes place at some limit in the proportion of its elements: such he supposes to be the case with salts and other crystallizable compounds. On the other hand, he supposes the limitations of the proportions of the elements of gaseous compounds to arise from the elastic form which they assume in certain stages of combination. This hypothesis was supported by so many striking facts, that it was thought by some to explain in general the cause of limited proportions. All agreed, that whatever might be the true theory, the causes pointed out by Berthollet had considerable influence in the composition and decomposition of bodies, but they saw at the same time numerous cases in which this hypothesis failed to explain the facts.

Chemists have, from the earliest times, been acquainted with those points of limitation which we call mutual saturation, and have been long familiar with those limited augmentations of their proportions, called by some doses and by others particles. Among the oxyds of metals, which had been little examined before the time of Lavoisier, it was found, that instead of having an infinite number of means between the lowest and highest stages of oxydation, only a certain number of oxyds of each metal could be formed, in which the ratio of the metal to the oxygen is uniform. Many of the salts in the same way are formed by limited doses of acid. Some of the facts in the latter have been explained on Berthollet's hypothesis, while its application

THEORY.

to the former facts is totally insufficient. Long previous to the true cause of these limited doses, the facts were so conspicuous, that a decided nomenclature was adopted for the purpose of expressing these different stages of combination. The oxyds have been distinguished by the Greek numerals *prot*, *deut*, *trit*, &c. The salts containing two doses of acid have been called *super-salts*; and those containing an extra dose of base, have been called *sub-salts*.

Although chemists have frequently used a language which appeared to shew their acquaintance with the real cause of the definite proportions, such as one compound being forced by one proportion, dose, or particle of one of its elements, and another with two proportions, doses, or particles: on the other hand, we find expressions which would favour the idea of indefinite proportions; such as bodies losing a small portion of their oxygen, or absorbing a little oxygen from the atmosphere. Salts are sometimes said to contain a slight excess of acid, or a small excess of base.

The most decided language used in any chemical work before the discoveries of Mr. John Dalton, giving any idea that the doses are limited by distinct atoms, will be found in a work by Mr. Higgins, entitled "A Comparative View of the Phlogistic and Antiphlogistic Theories." We beg leave to correct a mistake in a former article, in which we have entitled this work a Treatise on Phlogiston.

This work was written for the express purpose of combatting the phlogistic theory, and principally in answer to Mr. Kirwan's treatise of phlogiston. In order to shew the contradictions and absurdities of the phlogistic doctrine, which, under the name of phlogiston, confounded a number of bodies which were very different, he exhibited by diagrams a number of chemical operations, in which he supposed the elementary bodies concerned to be ultimate particles, and their immediate compounds molecules. He in the same diagrams also used numbers, which he supposed to be estimates of the strength of affinity of the combining particles. By this means he very successfully shewed many of the inconsistencies which must be admitted to explain the phenomena on the phlogistic theory. In this mode of proceeding, however, the numbers expressing the relative attractions, served his purpose much more than the consideration of the proportions being caused by distinct atoms; and the language which would induce the belief that he had such a conception of the nature of elementary matter, occurs only in a very few parts of his work.

After concluding that it is unnecessary to admit the existence of the imaginary substance phlogiston in sulphur, he concludes, in page 36, that sulphurous acid is compounded of one ultimate particle of sulphur with one of oxygen, and that sulphuric acid consists of one of sulphur and two of oxygen.

In the same page he also observes, that water is formed by one ultimate particle of water united to one of oxygen.

In page 81, he supposes sulphuretted hydrogen to consist of nine ultimate particles of sulphur with five of hydrogen. Previous, however, to this conclusion, he believes that the sulphur and hydrogen are not chemically combined, but that the sulphur is dissolved in hydrogen, as a salt dissolves in water.

After using arguments to shew, in answer to Mr. Kirwan, that the nitric acid does not contain what was thought to be phlogiston, he concludes, in page 132, with giving what he conceives to be its constituents, *viz.* that the nitrous oxyd consists of one ultimate particle of azote and one of oxygen; nitrous gas, of one of azote and two of oxygen; red nitrous vapour, one of azote and three of oxygen; straw-

coloured nitrous acid, one of azote to four of oxygen; and lastly, that the nitric acid is constituted by one of azote and five of oxygen. These facts are certainly very remarkable, as they agree with the conclusions in the present time, and give a strong proof of Mr. Higgins's genius at the time he wrote.

He does not, however, lay any stress upon these remarks, and was not probably aware that they would be confirmed by future research. We are induced to think so, from the manner in which he expresses himself in other parts of his work, in which he frequently speaks of the absorption of small portions of oxygen, and of bodies having a small portion of oxygen more than they can retain. This vague manner of speaking, and others which we do not immediately recollect, is sufficient to shew that Mr. Higgins had no fixed notions of the cause of definite proportions, and that the language in which he has used the words ultimate particles and molecules, was employed rather with a view to illustrate his examples, than to broach any new theory to explain indefinite proportions. Indeed it would have been inconsistent to have treated two subjects, so very different in their objects, in the same pages.

As a proof that there was nothing striking in the remarks in which the words ultimate atoms and molecules are mentioned, we only need refer to the article which Mr. Higgins himself quotes from the Analytical Review, written soon after the appearance of the work in question. The reviewer gives him the highest praise for the able manner in which he has refuted the doctrine of phlogiston, but does not even hint at his diagrams or the ultimate particles. Indeed we can venture to assert, that if no more had been said on the subject of definite proportions than is to be found in this work, we might yet have been as much in the dark as we were twenty years after the publication of Mr. Higgins's "Comparative View."

It was not enough to know that compound bodies were formed of particles, to enable us to explain the cause of definite proportions; and we want no greater proof of this, than the fact of the true cause not being known till twenty-eight years after Mr. Higgins had told us that one particle of sulphur and one of oxygen formed sulphurous acid, and that one to two formed sulphuric acid. These loose expressions were but a small step indeed towards the discovery of the atomic theory in its present form, which has placed chemistry on the same ground with that on which the discovery of the laws of gravity placed the science of astronomy.

We are inclined to believe that the first step towards this important discovery was given by Richter. He found, in the double decomposition of salts, that the acid of one salt was always just sufficient to saturate the base of the other, and *vice versa*. He also ascertained, that when one metal was precipitated by another, the oxygen of the precipitated metal was just what was required by the precipitating metal.

The inference to be drawn from these facts was, that if A combine with x to saturation, and B with y to the same; then, if A should be found to saturate y , B would also saturate x . This inference may be still further extended; for if A be a body capable of combining with B, they will mutually saturate each other.

It is the means of drawing these inferences arising from the mutual fitness of those parts of bodies which combine, that constitutes the importance of the atomic theory, and it is for the establishment of this new principle that we are indebted to Mr. John Dalton. When Mr. Higgins can shew, from the data given in his work, that similar infer-

ences

THEORY.

ences could be drawn, he then will be entitled to share in the merit of the discovery of the atomic theory. We say share with him, for we are firmly convinced that Mr. Dalton had never read Mr. Higgins's book previous to the publication of his own work.

We perfectly recollect the time, not more than four or five years ago, even when Mr. Dalton's book was before the public, very few chemists understood the true spirit of the atomic theory; and those who conceived they did understand it, in general discarded it. All knew that he considered compounds to be formed of atoms united 1 to 1, 1 to 2, 1 to 3, &c.: but it was not till the reciprocal fitness of these atoms with each other was found to agree with analysis, that it was generally received. When they saw that the numbers, which Dalton called the weights of the atoms, expressed the simple proportions in which bodies combine, they knew it could not be the effect of chance, and have willingly joined in the research. It is for this part of the discovery that Mr. Dalton justly merits the fame he has acquired.

We have given all the facts on which Mr. Higgins could possibly found his claim to the discovery; and we must leave it to our readers to judge, whether they contain the smallest data on which to establish what in the present time we call the atomic theory.

In all the chemical articles since the article IRON, we have had the greatest confidence in the atomic theory; and we have never failed to compare the analyses of different authorities with the results given by theory. We have in general found, that these results have been nearer to the best of these authorities, than they have been to each other.

We have already given an outline of the atomic theory, with a table of the weights of the simple atoms, and another of some of the most conspicuous compounds, in our articles *Definite Proportions*, and *Simple Bodies*.

The French chemists have adopted the atomic theory under another form, which will be found to agree with the language given by Berzelius, who uses the word *volume* for atom, as we have already explained in the article above alluded to.

Gay Lussac several years ago published a new law respecting the combination of gaseous bodies. He held that gases which combine chemically, either unite in equal volumes, or 1 to 2, or some multiple of 1, by a whole number. Although a number of facts seemed to agree with this law, the truth of it was doubted by some chemists, and principally because no apparent reason appeared for such a law.

In stating (under the article *Proportions*) the notion of Berzelius respecting volumes, we have pointed out a curious coincidence between the specific gravity and the weight of atoms of the gases, which has since been confirmed by Dr. Prout in *Dr. Thomson's Annals*. In order that the weights of the atoms may be equal to their specific gravities, we have there stated, that the number of particles in equal volumes of all gases must be equal, and the distance between the centres of the particles of all gases the same, so that the weights of equal volumes of different gases, would be as the weights of the atoms.

This would also require, that the attraction between the particles should either be the same in all, or that it should be nothing; and the distance of the particles be at points where the repulsion of the caloric atmosphere is balanced by the incumbent pressure.

The state here supposed, however, is not the case, since we find that the weights of the atoms of the gases generally are not equal to the specific gravity, when reduced to

the same standard, although it is strictly the case with a great proportion of them. And in those cases where they are not equal, the one is said to be some multiple of the other, by a whole number.

This circumstance favours the hope that some general law exists, by which the weights of the atoms of bodies are intimately connected with their specific gravities in the elastic form. When the specific gravity is double the weight of the atom, as is the case with oxygen, we have to suppose, that the particles are nearer each other in the proportion of 2 to 1, or that two particles come together, and are surrounded by the caloric, which belongs to one of them in their single state.

It would appear that the oxygen puts on this single state of existence in the formation of carbonic oxyd, because that gaseous body contains only one atom of oxygen; hence its specific gravity is the same as if it were formed from a gaseous oxygen of half the real specific gravity united to an atom of carbon without any change of volume, the same as takes place when sulphur or carbon is burned in oxygen gas. Hence we may explain the great tendency that oxygen has to combine in double doses with bodies, as is the case with carbon, sulphur, phosphorus, iron, and many other bodies.

We have also an instance of a compound gaseous body becoming of double the specific gravity which would be expected in olefiant gas, which is composed of an atom of carbon and an atom of hydrogen. The specific gravity (hydrogen being 1) ought to be $1 + 5.4 = 6.4$; but in fact it is about the double of this. Hence we should conclude, that the repulsion between the particles is halved, or that the compound atoms have united in pairs, by which the density is doubled.

Theory of the Manufacture and Production of Bread, in Rural Economy, the explanation of the principles and practices on which it depends in different cases. The means which are employed in such cases are mostly well understood; but the principles upon which they depend are far from being so well known. The writer of a late work on the "Elements of Agricultural Chemistry," has, however, thrown some light on this hitherto intricate subject. He has noticed, that a number of the changes taking place in the vegetable principles, depend upon the separation of oxygen and hydrogen as water from the compound; but that there is one of very great importance, in which a new combination of the elements of water is the principal operation: this is in the manufacture of bread. When any kind of flour, which consists principally of starch, is made into a paste with water, and immediately and gradually heated to about 440° , it increases, it is said, in weight, and is found entirely altered in its properties; it has lost its solubility in water, and its power of being converted into sugar. In this state it is unleavened bread.

And when the flour of corn, or the starch of potatoes, mixed with boiled roots of the same kind, is made into a paste with water, kept warm, and suffered to remain thirty or forty hours, it ferments, carbonic acid gas is disengaged from it, and it becomes filled with globules of elastic fluid. In this state it is raised dough, and affords by baking leavened bread; but this bread, it is said, is sour and disagreeable to the taste; and that leavened bread for use is made by mixing a little dough that has fermented, with new dough, and kneading them together, or by kneading the materials for the bread with a small quantity of yeast.

It is stated, that in the formation of wheaten bread, more than one-fourth of the elements of water combine with the flour;

flour; that more water in proportion is consolidated in the formation of bread from barley, and still a larger quantity in that from oats; but that the gluten in wheat, being in much larger quantity than in other grain, seems to form a combination with the starch and water, which renders wheaten bread more digestible than other species or kinds of bread.

On this principle too it is probable, that this sort of bread may be more suitable and proper for the less laborious classes of society, though the other kinds may be equally or more nourishing and lasting for those who are engaged in hard work.

THEOSOPHISTS, the denomination of a class of philosophers, who profess to derive their knowledge of nature from divine revelation. Not contented with the natural light of human reason, nor with the simple doctrines of scripture understood in their literal sense, these persons have recourse to an internal supernatural light, superior to all other illuminations, from which they pretend to derive a mysterious and divine philosophy, manifested only to the chosen favourites of heaven. They boast, that, by means of this celestial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have access to the most sublime secrets of nature. They ascribe it to the singular manifestation of divine benevolence, that they are able to make such an use of the element of fire, in the chemical art, as enables them to discover the essential principle of bodies, and to disclose stupendous mysteries in the physical world. (See *FIRE Philosophers*.) They even pretend to an acquaintance with those celestial beings, which form the medium of intercourse between God and man, and to a power of obtaining from them, by the aid of magic, astrology, and other similar arts, various kinds of information and assistance. This they affirm to have been the ancient secret wisdom, first revealed to the Jews under the name of Cabbala, and transmitted by tradition to posterity. Philosophers of this class have no common system; but every one follows the impulse of his own imagination, and constructs an edifice of fanaticism for himself. They only agree in abandoning human reason, and pretending to divine illumination. Many traces of the spirit of Theosophism are to be found in the whole history of philosophy, in which fanatical and hypocritical pretensions to divine illumination frequently occur. Among moderns, the first name that is mentioned with any distinction in this class of philosophers is Paracelsus. (See his biographical article.) He was succeeded by Robert Fludd, who compounded into a new mass of absurdity all the mysterious and incomprehensible dreams of the Cabbalists and Paracelsians. He supposed two universal principles, the northern or condensing power, and the southern or rarefying power; and over these he placed innumerable intelligences and geniuses, and called together whole troops of spirits from the four winds, to which he committed the charge of diseases. (See his article.) Another dazzling luminary in the constellation of Theosophists was Jacob Boehmen. See **BEHMEN**.

A more scientific Theosophist than Boehmen was Van Helmont. (See **HELMONT**.) The most elegant and philosophical of all the Theosophists was Peter Poiret, who was born at Metz in the year 1646, and educated in the academy of Basil. In 1668 he became a student in the university of Heidelberg, with a view of qualifying himself for the clerical profession, and in 1672 he assumed the character of an ecclesiastic in the principality of Deux-Ponts. After a severe fit of illness, he wrote his "Cogitationes Rationales de Deo, Anima, et Malo," in which he mostly followed the principles of Des Cartes, having in his youth studied the

Cartesian philosophy; a work which he defended against the censures of Bayle. Being obliged by the public tumults to withdraw from his clerical cure, he removed to Holland, and afterwards to Hamburg, where he became acquainted with the celebrated mystic Mad. Bourignon, and enlisted himself in the number of her disciples. Abandoning Cartesianism, and fascinated with Bourignonian mysticism, he rejected the light of reason as useless and dangerous, and inveighed against every kind of philosophy that was not the effect of divine illumination. Towards the close of his life he settled at Rheinburg, in Holland, and employed himself in writing mystical books; such were his treatises "De Oeconomia Divina," "De Eruditione Triplici," and the last edition of his "Cogitationes Rationales." He died in the year 1719. Some of his mystical notions may be collected from the preliminary dissertation prefixed to his works; they are such as these: "It hath pleased God, in order that he may enjoy a vivid and delightful contemplation of himself, beyond that solitude which belongs to the divine essence, to create external beings in whom he may produce an image of himself. The essence of the human mind is 'thought,' capable and desirous of light, and joyful complacence; the properties in which it bears a resemblance of the divine essence. Nothing is more intimate or essential to the mind than this desire; by which it is borne always towards the true and infinite good. In order to satisfy this desire, the illumination of faith is necessary; by means of which the mind, conscious of its weakness and impotence, disclaims all the fictions of human reason, and directs itself towards God with an intense and ineffable ardour, till, by the silent contemplation of him, it is filled with tranquillizing light and joyful complacence; although, whilst oppressed with the load of mortality, it cannot behold his unveiled face. From this divine illumination proceeds the most pacific serenity of mind, the most ardent love of God, and the most intimate union with him."

To the class of Theosophists it has been usual to refer the entire society of *Rosycrucians*; which see.

It will be sufficient to observe, at the close of this article, that the whole system of Theosophism is founded in delusion, and that it is injurious both to philosophy and religion. These supposed illuminations are to be ascribed either to fanaticism or to imposture. The fastidious contempt, with which these pretenders to divine wisdom have treated those who are contented to follow the plain dictates of common sense, and the simple doctrine of scriptures, has unquestionably imposed upon the credulous vulgar, and produced an indifference to rational enquiry, which has obstructed the progress of knowledge. And their example has encouraged others to traduce philosophy and theology in general, by representing them as resting upon no better foundation than enthusiasm and absurdity. It is to be charitably presumed, that these deluded visionaries have not been themselves aware of the injury which they have been doing to the interests of science and religion. Nevertheless, it must be regretted, both on their own account, and on account of the multitudes they have misled, that whilst they have thought themselves following a bright and steady luminary, they have been led astray by wandering meteors. Brucker by Enfield.

THEOTOCUS, DEIPARA. See *MOTHER of God*.

THEOXENIA, Θεοξενια, in *Antiquity*, a festival in honour of all the gods, and celebrated in many cities of Greece, but especially Athens.

THEOXINI MALAGMA, the name of a sort of cataplasm, good against pains of the feet.

THERA, in *Ancient Geography*, one of the islands called

Sporades, in the *Ægean* sea, between the island of Crete and the Cyclades. It is said to have taken its name from Theras, a prince of the race of Cadmus, who removed from Lacedæmon into this island, which was occupied by the descendants of the Memblariani, who had possession of it 1550 years before our era; whereas Pliny says that it first appeared in the fourth year of the 135th olympiad. This island is now called *Santorin*; which see.—Also, a town of the island of the same name.—Also, a town of Asia Minor, in Caria, between Idymus and Pyltus.—Also, a town of Asia, in Sogdiana.

THERAMBUS, a town of Macedonia, in the peninsula of Pallené.

THERAMNÆ, a town of Asia Minor, in Lycia; consecrated to Apollo.

THERAPEUTÆ, *θεραπευται*, a Greek term signifying servants, more especially those employed in the service of God. The Greeks gave the appellation *therapeutæ* to such as applied themselves to a contemplative life, whether it were from the great concern they had for their souls, or from the particular mode and manner of their religion; the word *θεραπευσις*, whence *therapeutæ*, signifying the care a physician takes of his patient, or the service any one renders another.

Philo, in his first book of the *Contemplative Life*, relates, that there were a people spread throughout most of the known world, but particularly throughout Egypt, and about Alexandria, who renounced their friends, their goods, &c. and who, after discharging themselves of all temporal concerns, retired into solitary places, where they had each their separate mansion, called *semnium*, or *monastery*, and placed their whole felicity in the contemplation of the divine nature.

The principal society of this kind was formed near Alexandria, where they lived, not far from each other, in separate cottages, each of which had its own sacred apartment, to which the inhabitant retired for the purposes of devotion. After their morning prayers, they spent the day in studying the law and the prophets, endeavouring, by the commentaries of their ancestors, to discover some allegorical meaning in every part. They also amused themselves with composing sacred hymns in various kinds of metre. Six days of the week were thus passed in solitude. On the seventh day they met, decently clothed, in a public assembly, where, seated according to their age, they held the right hand between the breast and the chin, and the left at the side. Then one of the elders, stepping to the middle of the assembly, discoursed, gravely and calmly, on the doctrines of the sect; the audience remaining silent and occasionally expressing their approbation by a nod. The chapel in which they assembled was separated into two apartments, one for the men, the other for the women. At the close, the speaker sung a hymn of praise to God, in the last verse of which the whole assembly joined. On great festivals, sacred music was performed, accompanied with solemn dancing; and these vigils were continued till morning, when the assembly, after a morning prayer, in which their faces were directed towards the rising sun, was broken up. Such was their abstemiousness, that they commonly ate nothing before the setting sun, and often fasted two or three days. They wholly abstained from wine, and their ordinary food was bread and herbs.

There are two points relating to these *therapeutæ* exceedingly controverted among critics, *viz.* 1. Whether they were Jews or Christians; and, 2. If they were the latter, whether they were monks or seculars?

Mosheim affirms, that the *therapeutæ* were neither Chris-

tians nor Egyptians, as some have erroneously imagined: they were undoubtedly Jews; nay, they gloried in that title, and styled themselves, with particular affectation, the true disciples of Moses, though their manner of life was equally repugnant to the institutions of that great lawgiver, and to the dictates of right reason, and shewed them to be a tribe of melancholy and wrong-headed enthusiasts.

Camel also, in his Dictionary of the Bible, alleges a variety of reasons to prove, that the *therapeutæ* were Jews and not Christians; and that they were not monks in the sense which ecclesiastical writers affix to this term. Some have imagined that they were judaizing Gentiles; but Philo, by classing them with the Essenes, evidently supposes them to be Jews. Others have maintained, that they were an Alexandrian sect of Jewish converts to the Christian faith, who devoted themselves to a monastic life. But this is impossible; for Philo, who wrote before Christianity appeared in Egypt, speaks of this as an established sect. From a comparison of Philo's account of this sect with the state of philosophy in the country where it flourished, we may reasonably conclude, that the *therapeutæ* were a body of Jewish fanatics, who suffered themselves to be drawn aside from the simplicity of their ancient religion by the example of the Egyptians and Pythagoreans. It is uncertain how long this sect continued; but it is thought not improbable, that, after the appearance of Christianity in Egypt, it soon became extinct. See *ESSENES*.

THERAPEUTICE, **THERAPEUTICS**, *θεραπευτικη*, formed from *θεραπευσις*, to attend, to nurse, cure, &c. that part of medicine which is employed in seeking out remedies against diseases, and in prescribing and applying them to effect a cure.

Therapeutice teaches the use of diet, pharmacy, surgery, and the *methodus medendi*.

THERAPEUTICĒ is also used figuratively, in speaking of the mind, and of discourses made to correct the errors and defects of it.

Such is the *Therapeutice* or *Therapeutics* of Theodoret; being a treatise against the errors of unwholesome opinions of the Greeks, *i. e.* the heathens.

THERAPHIM, or **TERAPHIM**, an Hebrew term, which has given great exercise to the critics. We meet with it thirteen or fourteen times in Scripture, where it is commonly interpreted *idols*: but the rabbins are not contented to have them simply signify idols, but will have it denote a peculiar sort of idols or images intended for the knowledge of futurity, *i. e.* oracles.

R. David de Pomis observes, that they were called *theraphim*, from *רפח*, *raphah*, to leave, because people quitted every thing to consult them.

Others hold, that the *theraphim* were brazen instruments which pointed out the hours and minutes of future events, as directed by the stars.

R. Eliezer tells us the reason why the rabbins will have the *theraphim* to speak, and render oracles: it is, says he, because it is written in the prophet Zechariah, x. 2. "The *theraphim* have spoken vain things."

The same rabbin adds, that to make the *theraphim*, they killed a first-born child, clove his head, and seasoned it with salt and oil: that they wrote on a plate of gold the name of some impure spirit, laid it under the tongue of the dead, placed the head against the wall, lighted lamps before it, and prayed to it, and that it then talked with them.

Vorstius also observes, that, beside the passage of Zechariah, just quoted, it appears likewise from Ezekiel, xxi. 21. that the *theraphim* were consulted as oracles.

F. Kircher directs us to seek the origin of the *theraphim*

in Egypt; adding, that the word is Egyptian. Spencer, in his dissertation on the *urim* and *thummim*, maintains the word to be Chaldee, and to signify the same with *seraphim*: the Chaldeans being frequently known to change the *ש* into *ס*, that is *s* into *t*. He adds, that those images were borrowed from the Amorites, Chaldeans, or Syrians; and that the *Serapis* of the Egyptians is the same thing with the theraphim of the Chaldeans. See Selden de *Diis Syris*, synt. i. cap. 2.

Calmet observes, that the figure of a winged serpent, called *seraph*, whence the name *seraphim*, has given rise to the appellation *theraphim*, because in the *abraxas* and other talismans of the ancients, which are real theraphims, we find the figures of serpents both with and without wings; whence he infers, that the theraphims of Laban, which were stolen by Rachael, were real talismans. Jurieu conjectures, that these theraphims were the penates, or household gods of Laban, which, he says, were the souls of the heroes of families, deified and worshipped; and he adds, that the theraphims of Laban were the images of Noah, the restorer of the human race, and of Shem, the chief of the family of Laban. But Calmet, in reply to this conjecture, observes, that it is by no means credible, that the worship of the penates and lares was known in the time of Laban; and that it is not likely, that Laban should have ranked among the gods Noah and Shem, who had died so near his own time: for Noah died A.M. 2006, and Shem A.M. 2158, about eighty-seven years before Jacob came to Mesopotamia after Laban.

THERAPIDION, in *Botany*, a name given by some authors to the common oyster-green, or sea-laver, a substance of the tremella kind.

THERASIA, in *Geography*, a small rocky island in the Grecian Archipelago, separated from the N.W. coast of Santorin (the ancient Thera) by a narrow channel, which forms a secure harbour for boats; 3 miles N. of St. Nicolo. Therasia is said by Tournefort and Sonnini to be the present *Aspronisi* (which see); but Olivier mentions them as distinct islands. Therasia, says this last-mentioned traveller, on which Ptolemy places a town, and which Pliny conjectures, with reason, to have been detached from Thera, cannot be taken for *Aspronisi*, nor the latter for the former, as Tournefort imagines. *Aspronisi* is not large enough to have had upon it the smallest village, or the smallest habitation; whereas Therasia has sufficient extent, and its territory is sufficiently good, to have been always the site of a town, as one is still to be seen there at the present day.

THERESA, a river of Africa, which runs into the Atlantic, S. lat. 13°.

THERESA, *Order of Maria*, a military order instituted by the empress-queen in Germany, on the 18th of June, 1757, and composed of two classes, *viz.* grand crosses and knights. To these the emperor Joseph II., in the year 1765, added an intermediate class, under the appellation of commanders. The number of knights is not fixed, and the emperor is grand-master. The badge of the order is, "a cross of gold, enamelled white, edged with gold;" on the centre are the arms of Austria, *viz.* "gules, a fesse-argent, encircled with the word *Fortitudini*;" on the reverse is "a cipher of the letters M. L. F. in gold, on an enamelled green ground." The badge is worn pendant to a striped crimson and white ribbon.

THERGUBIS, in *Ancient Geography*, a town of Asia, in the interior of Mesopotamia, situated on the bank and towards the source of the river Chaborras.

THERIACA, *Θηριακὰ*, *Treacle*, in *Medicine*, a name given by the ancients to various compositions esteemed good

against poisons; but afterwards chiefly restrained to what, by way of distinction, has been called *theriaca Andromachi*, or *Venice treacle*: but now altogether out of use.

This is a compound of no less than sixty-four drugs, prepared, pulverized, and reduced, by means of honey, into an electuary. The basis or foundation of the composition is viper's flesh. M. Charas has written a particular history of the animals, plants, and minerals, which enter the composition of this famed remedy.

It is said to be sovereign against the bites of venomous beasts, and in the wind-colic; and was also used in intermitting fevers, and in cases requiring perspiratives and diaphoretics; also in continual fevers, especially such as are malignant, and where the pulse is low and ticking; and in the small-pox and measles: and, as most of the ingredients of it are very hot, in all diseases where the natural heat is weak and languid.

Andromachus, Nero's physician, passes for the inventor of the theriaca; at least, it was he who gave the first description of it in elegiac verses; his son did the same in prose, and Damocrates in iambs.

Anciently, the treacle made at Venice had all the vogue: and many still retain the ancient prejudice; but it has been since prepared at Montpellier, at Paris, and at London, with as much advantage as at Venice.

There is another vulgar kind of theriaca, called *diatesaron*, because it only consists of four ingredients.

Treacle-water and treacle-vinegar are found good preservatives against putrid air, whether by only being smelt at, or by rubbing the wrists, temples, and nose with them.

THERIACA Rusficorum, a name given to garlic, from its use as an antidote against the contagion of pestilential and other putrid disorders.

THERIOMA, from *θρησκω*, to rage, in *Surgery*, a malignant ulcer.

THERMA, in *Ancient Geography*, a town of Cappadocia, on the route from Tavia to Casarea, between Tavia and Souda. Anton. Itin.—Also, a town situated on the confines of Macedonia, or rather of Thessaly, towards Thermopylæ. This town was situated on the gulf called Thermæus, whence its name.

THERMA Pythia, baths of Asia Minor, in Bithynia. Propertius mentions this place, and says that Justinian constructed here a bath for public use, and a canal to conduct into it fresh water, and that he also provided others, which indicated a magnificence truly royal.

THERMÆ, *Σημαί*, in *Architecture*, ancient buildings, furnished with baths, especially of the hot kind.

Among the noblest monuments of ancient Rome, are reckoned the thermæ, or baths of Dioclesian. See **BATHS**.

Thermæ, or hot springs, it is commonly argued, owe heat to a coagulation, or effervescence, of the minerals in them. Though Dr. Woodward ascribes it to the subterraneous heat, or fire, which communicates with them by some spiracle, or canal, whereby a greater quantity of heat is derived thither, than to ordinary springs. See **BATH**.

THERMÆ, in *Ancient Geography*, a place on the southern coast of Sicily. Pliny denominates this place a Roman colony; and Antonine calls the sources of the hot water which gave the name of Thermæ to this place "Aque Larodæ." There were also baths at Selinonti in Sicily, called Thermæ Selinuntia. The name *thermæ* was also given to those highly saline warm waters that were found in the neighbourhood of Corinth.

THERMÆUS SINUS, a gulf of the Ægean sea, on the coast of Macedonia.

THERMASMA, a word used by some of the ancients

to express any thing that warms the body, and by others particularly for a warm fomentation, prescribed by Hippocrates for removing pains in the side, and giving ease in pleurifies.

THERMES, in *Ancient Geography*, a town of Hispania Citerior, S. of Numantia.

THERMI, in *Geography*, a town of Asiatic Turkey, in the province of Natolia; 24 miles N. of Burfa.

THERMIA, an island in the Grecian Archipelago, so called from its abounding with hot springs. It is not so mountainous as some of the other islands, and the soil, when well cultivated, produces very large quantities of barley, wine, and figs. The island also affords plenty of honey, wax, partridges, a great quantity of fine silk, and as much cotton as the inhabitants require for their own use. The Greek Christians in this island are computed at 16,000. Thermia is the see of a bishop, and contains fifteen or sixteen churches, and several convents. On the island are still visible the ruins of two cities; one of which, on the south coast, must have been of extraordinary splendour. N. lat. $37^{\circ} 20'$. E. long. $24^{\circ} 32'$.

THERMIA, a town and capital of the island of Thermia. N. lat. $37^{\circ} 24'$. E. long. $24^{\circ} 26'$.

THERMOMETER, **THERMOMETRUM**, derived from $\theta\epsilon\rho\mu\omicron\varsigma$, heat, and $\mu\epsilon\tau\rho\epsilon\upsilon$, to measure, an instrument shewing, or rather measuring, the increase and decrease of the heat and cold of the air.

The degree of heat, as ascertained by a thermometer, is only to be considered in relation to the surrounding bodies, by virtue of which a body supports the equilibrium of temperature, when it is in the neighbourhood of bodies equally heated: thus, if a thermometer stands at 60° , both in a vessel of water and in another of mercury, we may infer that the water and the mercury may be mixed without any change of their temperature; but the absolute quantity of heat contained in equal weights, or in equal bulks, of any two bodies at the same temperature, is by no means the same. See **HEAT**.

The general principles upon which the construction and use of thermometers, or measurers of heat depend, are stated and explained under the articles **CALORIC**, **COLD**, **CONGELATION**, **FREEZING**, **HEAT**, &c.

It will be sufficient to observe in this place, that the well-known and most general effect of heat, whether it be obtained by compressing a certain substance into a narrower space, so that a quantity of heat may come out of it and be communicated to certain bodies, or by expanding a certain substance into a larger space, so that it may absorb a quantity of heat from surrounding bodies, and thus cool these bodies, or in whatever other way it be procured, is a dilatation of bodies, or an augmentation of their bulks. The contrary effect is produced by cold, *i. e.* by a diminution of the free caloric. It must, however, be observed, that bodies of equal bulks, but of different kinds, are not expanded alike by being heated to the same degree; nor are the increments of bulk in the same body always proportional to the quantities of heat which are communicated to it. *E. gr.* if a given quantity of water, by being heated to a certain degree, be increased in bulk one cubic inch, the addition of double or treble that quantity of heat will not increase its bulk two or three cubic inches respectively; therefore the expansions of water are not proportional to the increments of heat.

The only practicable method of measuring the expansions of fluids, is by inclosing them in certain vessels, and by measuring that part of the cavity of each vessel which is occupied by the particular fluid which fills it in different temperatures.

It is evident, that the substance of the vessel is also expanded by the heat, and of course its cavity is enlarged: Therefore, when we find that the bulk of the fluid is increased, that apparent increment is only the difference between the enlarged capacity of the vessel and the increased bulk of the fluid. For this reason those vessels must be made of such substances as are least expansible by heat. Indeed glass is the substance which is universally used for such purposes, both on account of its little expansibility, and of its transparency, besides its having other remarkably useful properties.

A glass vessel filled to a certain degree with a liquid, for the purpose of shewing the expansion of that liquid in different temperatures, or for the purpose of shewing the temperature by the corresponding expansion of that liquid, is called a *thermometer*.

The thermometer and thermoscope are ordinarily accounted the same thing: Wolfius, however, makes a difference; but shews, at the same time, that what we call thermometers are, in reality, no more than thermoscopes.

The invention of the thermometer is attributed to several persons by different authors, *viz.* to Sanctorio, Galileo, Father Paul, and Drebbel. The invention is ascribed to Cornelius Drebbelius of Alcmæer, about the beginning of the seventeenth century, by his countrymen Boerhaave (*Chem. i. p. 152. 156.*) and Muschenbroeck, *Introd. ad Phil. Nat. vol. ii. p. 625.*

Fulgenzio, in his life of Father Paul, gives him the honour of the first discovery. Vincenzio Viviani (*Vit. de l'Galil. p. 67.* See too *Oper. di Galil. pref. p. 47.*) speaks of Galileo as the inventor of thermometers. But Sanctorio himself (*Com. in Galen. Art. Med. p. 736—842. Com. in Avicen. Can. Fen. i. p. 22. 78. 219.*) expressly assumes this invention; and Borelli (*De Mot. Animal. ii. prop. 175.*) and Malpighi (*Oper. Posth. p. 30.*) ascribe it to him without reserve. Upon which Dr. Martine remarks, that these Florentine academicians are not to be suspected of partiality in favour of one of the Patavinian school. But whoever was the first inventor of this instrument, it was very rude and imperfect; and as the various degrees of heat were indicated by the different contraction or expansion of air, it was afterwards found to be an uncertain and sometimes a deceiving measure of heat, because the bulk of air was affected, not only by the difference of heat, but likewise by the variable weight of the atmosphere.

There are various kinds of thermometers; the construction, defects, theory, &c. of which, are as follow:

Construction of the Thermometer, depending on the Rarefaction of the Air.—This aerial thermometer, which was first invented by Drebbel, consists of a glass tube BE (*Plate XVI. Pneumatics, fig. 1.*), connected at one end with a large glass ball A, and at the other end immersed in an open vessel, or terminating in a ball DE, with a narrow orifice at D; which vessel, or ball, contains any coloured liquor that will not easily freeze. Aqua fortis tinged of a fine blue colour with solution of vitriol or copper, or spirit of wine tinged with cochineal, or Brasil wood, will answer this purpose. But the ball, A, must be first moderately warmed, so that a part of the air contained in it may be expelled through the orifice D; and then the liquor pressed by the weight of the atmosphere will enter the ball DE, and rise, *e. g.* to the middle of the tube at C, at a mean temperature of the weather; and in this state the liquor by its weight, and the air included in the ball A, &c. by its elasticity, will counterbalance the weight of the atmosphere. As the surrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower

THERMOMETER.

lower ball, and consequently its surface will descend; on the contrary, as the ambient air becomes colder, that in the ball is condensed, and the liquor pressed by the weight of the atmosphere will ascend: so that the liquor in the tube will ascend or descend more or less, according to the state of the air contiguous to the instrument. To the tube is affixed a scale of the same length, divided upwards and downwards from the middle, C, into one hundred equal parts, by means of which the ascent and descent of the liquor in the tube, and consequently the variations in the cold or heat of the atmosphere, may be observed.

It must be acknowledged, that the expansion of elastic fluids affords, in some cases, a test of heat, which is very convenient from its great delicacy, and because a very small quantity of heat is sufficient to raise their temperature very considerably.

A similar thermometer may be constructed by putting a small quantity of mercury, not exceeding the bulk of a pea, into the tube B C (*fig. 2.*) thus bent in wreaths, that taking up the less height, it may be the more manageable and less liable to harm; divide this tube into any number of equal parts to serve for a scale.

Here the approaches of the mercury towards the ball, A, will shew the increase of the degree of heat. The reason is the same as in the former.

The defect of both these instruments consists in this, that they are liable to be acted on by a double cause: for, not only a decrease of heat, but also an increase of weight of the atmosphere, will make the liquor rise in the one, and the mercury in the other; and, on the contrary, either an increase of heat, or decrease of weight of the atmosphere, will make it descend.

In winter, for example, the liquor would rise and sink too much; for a frost condensing the internal air, the liquor would ascend, but as the air is heavier in frosty weather, its pressure on the liquor in the vessel D E (*fig. 1.*) being increased, would raise the liquor still higher in the tube, and thus indicate a degree of cold greater than it really is. On the other hand; if the weather grows warm, as it does in rainy weather in winter, the air in the ball will expand, and the liquor descend in the tube; but as the weight of the atmosphere is less in foul weather, the liquor in D E will be less pressed than it was, and suffer the liquor to descend more than it should do, and shew a greater degree of warmth than that of the ambient air. The reverse of this will happen in summer: for warm weather being fair weather, and the atmosphere being then heavier than usual, the liquor will be made to stand higher in the tube than it should do, and shew the degree of heat to be less than it really is. And as in summer, the weather becomes cold with rain; but the weight of the atmosphere being diminished, the liquor will not ascend so far as it ought to ascend by the condensation of the internal air, and therefore indicate the cold to be less than it really is: and when the two causes, thus contributing to the rise and fall of the liquor, act equally in opposite directions, the liquor would appear neither to ascend nor descend, whatever might be the changes in the temperature of the atmosphere, on account of equal corresponding variations in its gravity. Besides, the air in the ball, &c. is liable to be affected more or less in its elastic quality by the vapours that detach themselves from the included liquor according to the degree in which it is heated or cooled. For these and other measures, thermometers of this kind have been long diffused.

Instruments of this kind, when they are subject to the variations of the pressure of the atmosphere, as well as to those of its temperature, are properly called manometers,

and require, for enabling us to employ them as thermometers, a comparison with the barometer; while, on the other hand, they may be used as barometers if the temperature be otherwise ascertained. They are, however, very useful without this comparison, in delicate experiments of short duration; besides, the changes of the barometer are seldom very rapid, and they may also be wholly freed from the effects of the pressure of the atmosphere in various ways.

Bernoulli's method consists in closing the tube of a common barometer so as to leave the column of mercury in equilibrium with the air contained in the bulb at its actual temperature, and capable of indicating, by the changes of its height and of its pressure, any subsequent changes in the temperature of the air, which must affect both its bulk and its elasticity. (*See fig. 3.*) Mr. Leslie's photometer, or *Differential THERMOMETER* (which see), has some advantages which render it better than this instrument; but it can only be employed when the changes of the temperature can be confined only to a part of the instrument. The elasticity of the air contained in the bulb is here counteracted, not by the pressure of a column of mercury, but by the elasticity of another portion of air in a second bulb, which is not to be exposed to the heat or cold that is to be examined; and the difference of the temperatures of the two bulbs is indicated by the place of a drop of a liquid, moving freely in the tube which joins them.

M. Amontons, in 1702, with a view of perfecting the *aerial thermometer*, contrived his *universal thermometer*. Finding that the changes produced by heat and cold in the bulk of the air were subject to invincible irregularities, he substituted for these the variations produced by heat in the elastic force of this fluid. This thermometer consisted of a long tube of glass (*see fig. 4.*) open at one end, and recurved at the other end, which terminated in a ball. A certain quantity of air was compressed into this ball by the weight of a column of mercury, and also by the weight of the atmosphere. The effect of heat on this included air was to make it sustain a greater or less weight; and this effect was measured by the variation of the column of mercury in the tube, corrected by that of the barometer, with respect to the changes of the weight of the external air. This instrument, though much more perfect than those in the room of which it was substituted by its inventor, is nevertheless subject to very considerable defects and inconveniences. Its length of four feet renders it unfit for a variety of experiments, and its construction is difficult and complex: it is extremely inconvenient for carriage, as a very small inclination of the tube would suffer the included air to escape: and the friction of the mercury in the tube, and the compressibility of the air, contribute to render the indications of this instrument extremely uncertain. Besides, the dilatation of the air is not so regularly proportional to its heat, nor is its dilatation by a given heat nearly so uniform as he supposed. This depends, as the abbé Nollet has suggested, much on its moisture; for dry air does not expand near so much by a given heat, as air stored with watery particles; which by being converted into steam, very much increase the seeming volume of the air. For these and other reasons enumerated by M. de Luc, (*Récherches sur les Mod. de l'Atm. tom. i. p. 278, &c.*) this instrument was imitated by very few, and never came to be of general use.

Construction of the Florentine Thermometer.—The academists del Cimento, about the middle of the seventeenth century, considering the inconveniences of the air-thermometers above described, attempted another, that should measure heat and cold by the rarefaction and condensation of spirit of wine; though much less than those of air, and consequently

THERMOMETER.

frequently the alterations in the degree of heat likely to be much less sensible.

The spirit of wine was enclosed in glass tubes, hermetically sealed; so that these thermometers could be subject to no inconvenience by the evaporation of the liquor, or the variable gravity of the incumbent atmosphere. Instruments of this kind were first introduced into England by Mr. Boyle, and they were soon universally used among philosophers in other countries. The *Florentine* thermometer consists of a small narrow tube B C D (*fig. 5.*) connected with a glass ball A. The tube should be procured as cylindrical as possible: and it may be tried, by putting into one end of it as much mercury as will fill the length of one inch, and letting this quantity of mercury pass from one part of the tube to another, through its whole length; measure with compasses the length it occupies in every part of the tube; and if it every where takes up an inch, the tube is cylindrical, and a scale of equal divisions will agree with it: otherwise it will be longer where the tube is smaller, and shorter than an inch where the tube is larger; and in this case, the divisions must be suited to the contents of the bore. The glass ball may then be joined to the tube, and a small cavity be made at the other end. Fill the ball and tube with rectified spirit of wine to a convenient height, as to C, when the weather is of a mean temperature, which may be done by inverting the tube into a vessel of stagnant coloured spirit, under a receiver of the air-pump, or by many other ways. The spirit may be coloured by pouring a quantity of it on small pieces of turmeric, which will hereby receive a red tincture; and the spirit may be repeatedly filtrated through brown paper, in order to separate from it the coarser particles of the root. Some persons, in filling the ball and tube, for preventing the spirit from wholly descending into the ball in winter, recommend putting the ball into a lump of snow, mixed with salt; or if the instrument be made in summer, into spring-water impregnated with salt-petre, that the condensed spirit may shew how far it will retire in extreme cold. If it rises to too great a height from the ball, part of it is to be taken out; and that the tube may not be made longer than necessary, it is convenient to immerge the ball, filled with its spirit in boiling water, and to mark the farthest point to which it then rises. When the thermometer is properly filled, with a lamp heat the little bubble left at the end of D red-hot, and seal it hermetically, leaving, as Dr. Defaguliers recommends, in the thermometer only the third part of the air that was in it, which will give room to the dilatation of the spirit; and this rarefied air will prevent the air left in the spirit, even after the air-pump has been applied, from dividing the spirit by its expansion. To the tube apply a scale, divided into one hundred equal parts, from C towards D, and also from C towards B.

Now, spirit of wine rarefying and condensing very considerably; as the heat of the ambient air increases, the spirit will dilate, and consequently will ascend in the tube; and as the heat decreases, the spirit will descend: and the degree or quantity of ascent and descent will be seen in the scale. Yet as the ratio of yesterday's heat to to-day's is not hereby discovered, this instrument is not strictly a thermometer, any more than the former.

It is to be here observed, 1. That as the natural gravity of the liquor makes it tend downwards, so it resists its ascent out of the ball into the tube; and that the more, as it rises higher; for which reason, some have advised to have the tube horizontal.

2. Since there must of necessity be some air left in the void part of the tube, over the liquor, that air, by its elasticity, will tend downwards, and of consequence will resist

the rise of the liquor, and be compressed by it as it does rise: its elasticity therefore is thus increased.

3. Since it is found from experience, that a less degree of heat is communicated more easily to the spirit of wine in the ball than a greater, the rarefactions of the spirit of wine are not proportionable to their producing causes; especially since a greater degree of heat finds more liquor in the tube than a less does, to which, notwithstanding, the heat may be more easily communicated than to that stagnating in the ball.

4. Spirit of wine is incapable of bearing very great heat or very great cold. It boils sooner than any other liquor, and, therefore, the degrees of heat of boiling fluids cannot be determined by this thermometer. And though it retains its fluidity in pretty severe cold, yet it seems not to condense very regularly in them: and at Torneo, near the polar circle, the winter cold was so severe, as Maupertuis informs us, that the spirits were frozen in all their thermometers. So that the latitude of heat and cold, which spirit of wine is capable of indicating, is much too limited to be of very great or universal use. On these accounts, the Florentine thermometer, though it has been much used, is far from being an accurate measure of heat, &c. to which may be added what Dr. Halley observes in the *Philosophical Transactions*, that he has learned from those who have kept spirit of wine long, that it always loses part of its expansive force in course of time.

This objection, suggested by Dr. Halley, and often insisted on by others, has, according to Dr. Martine, no great weight. Well rectified spirit of wine, if sealed up in a glass, is in a considerable degree unalterable. It cannot evaporate; and by many years experience its force of expansion has continued the same; as, beside other observations, we know especially from the *Annual Registers* of M. de la Hire's spirit thermometer, that have been kept in the *Observatory* for many years.

Another great defect of these, and other thermometers, is, that their degrees are not comparable with each other. They mark, indeed, the different degrees of heat and cold; but each marks only for itself, and after its own manner; because they do not proceed from any point of heat, or cold, that is common to them all. It is with them as with two clocks, which for want of having been first set to the same hour by the sun, will, indeed, mark that one, two, or more hours are passed, but not what hour it is by the day. Nor can we be assured, that when the liquor is risen a degree in two different thermometers, they have both suffered the same impression of an equal additional heat: since the spirit of wine may not be the same in both; and, in proportion as the spirit is more or less rectified, it will rise more or less high by the same heat. Nor is this all; for in graduating thermometers, they often take equal lengths of the tube for equal ascents of the spirit: whereas, supposing the diameters of the tube equal throughout, which very rarely happens, there are so many irregularities within, that a certain length of tube sometimes requires double the quantity of liquor to fill it, that the same length in another tube of the same diameter requires. All which arises from the unequal thickneses of the parietes of tubes in different places; and from accidental prominences and cavities, always found in the inner surfaces of tubes; and especially from their being always bigger at one end than the other.

Besides, the divisions of the scale cannot accurately indicate the quantity of rarefaction, unless the proportion of the cavity of the tube D B to that of the ball A were known. Hence it is, that the comparison of thermometers becomes so precarious and defective. Yet the most curious and interesting use of thermometers is, what ought to arise from such

THERMOMETER.

such comparifon. It is by this we fhould know the heat or cold of another feafon, of another year, another climate, &c. and what is the greateft degree of heat or cold in which men and other animals can fubfift.

M. de Reaumur contriv'd a new thermometer for the purpofe; wherein the inconveniences above recited are propofed to be remedied. He took a large ball and tube, and knowing the content of the ball as well as that of the tube in every part, he graduated the tube, fo that the fpace from one divifion to another might contain a thoufandth part of the liquor, which liquor would contain one thoufand parts when it flood at the freezing point: then putting the ball of his thermometer, and part of the tube, into boiling water, he obferv'd whether it rofe eighty divifions; and if it exceeded thefe, he chang'd his liquor, and by adding water lower'd it, fo that on the next trial from the freezing point to the point of boiling water, it fhould only rife eighty divifions: but if the liquor, being too low, fell fhort of eighty divifions, he rais'd it by adding rectified fpirit to it. The liquor thus prepar'd fuit'd his purpofe, and ferv'd for making a thermometer of any fize, whole fcale would agree with his ftandard. Such liquor, or fpirits, being about the ftrength of common brandy, may eafily be had any where, or made of a proper degree of density by raifing or lowering it.

The abbé Nollet made many excellent thermometers upon M. de Reaumur's principle. Dr. Martine, however, expreffes his apprehenfions that thermometers of this kind are conftituted on principles, that will by no means be found fo accurate as were to be wifh'd and expected. The balls, or bulbs, being large, as three or four inches in diameter, are neither heated nor cool'd foon enough to fhew the variations in the heat of bodies, and in the weather. Small bulbs and fmall tubes, he fays, are much more convenient, and may be conftituted with fufficient accuracy. Though it muft be allow'd, that Reaumur, by his excellent fcale, and by depriving the fpirit of wine of its air, and expelling the air by means of heat from the ball and tube of his thermometer, has brought it to as great a degree of perfection as it may poffibly admit; yet it is liable to fome of the inconveniences of *spirit* thermometers, and much inferior to the *mercurial* thermometers. Thermometers of this kind, and thofe of mercury, do not agree in indicating the fame degrees of extreme cold; for when the mercury has flood at 22° below 0, the fpirit indicat'd only 18°; and when the mercury flood at 28° or 37° below 0, the fpirit refted at 25° or 29°. See the defcription of Reaumur's thermometer at large in Mem. de l'Acad. R. des Scienc. an. 1730, p. 645. Hift. p. 15. Ibid. an. 1731, p. 354. Hift. p. 7.

In 1740, M. Micheli du Creft conftituted a fpirit thermometer, to which he annexes four fcales befides its own, viz. that of the old thermometer in the Obfervatory at Paris, Reaumur's, de l'Ifle's, and Fahrenheit's. See *Fixed Points of THERMOMETERS*.

THERMOMETER, Mercurial. It is a circumftance of principal importance in the conftituted of thermometers, to procure a fluid that meafures equal variations of heat by correfponding equal variations in its own bulk or volume: and the fluid which poffeffes this effential requifite in the moft perfect degree is mercury: the variations in its bulk approaching nearer to a proportion with the correfponding variations of its heat than any other fluid. This general propofition M. de Luc has very elaborately evinc'd, by fhewing that the condenfations of fluids, which increafe in bulk when they freeze, are not proportional to the diminutions of heat; and that the dilatations of fluids, which are

eafily converted into vapour by heat, are not proportional to the augmentations of heat: whereas the bulk of mercury is not enlarg'd when it freezes, and it refifts evaporation more than every other liquid that has been ufed in the conftituted of thermometers. Befides, it is of all liquids the moft eafily purg'd of its air. It is alfo the moft proper for meafuring very confiderable variations of heat; for, if a fcale be graduated with 0 at the point of melting ice, and 80 at that of boiling water, mercury well purg'd of its air will indicate feven times this difference of heat, or 561 degrees in fuch a fcale; as it will condense without freezing to - 261 of this fcale, and expand without boiling to 300 of the fame fcale. Mercury is alfo more fenfible than any other fluid, air excepted, and conforms more readily to the feveral variations of heat. Moreover, as mercury is an homogeneous fluid, it will in every thermometer exhibit the fame dilatation or condenfation by the fame variations of heat. The expansion of mercury is fcarcely lefs regular than that of folids, which probably approaches the neareft to the fteps of the natural fcale, though not without fome inequality; and therefore a portion of mercury inclos'd in a bulb of glafs, having a fine tube connect'd with it, forms a thermometer the moft convenient and probably the moft accurate of any, for common ufe; the degrees correfponding very nearly with thofe of the natural fcale, although, according to the moft accurate experiments, they appear to indicate, towards the middle of the common fcale of Fahrenheit, a temperature two or three degrees too low. There is an inequality of the fame kind, but ftill greater, in the degrees of the fpirit thermometer; and this inftrument has alfo the difadvantage of being liable to burft in a heat below that of boiling water; neverthelefs, it is well calculated for the meafurement of very low temperatures, fince pure alcohol has never yet been frozen, while mercury has been reduced to a folid by the cold of Siberia and of Hudfon's Bay; but both mercury and linfeed oil fupport a heat of between 500° and 600°, without ebullition.

In order to render thermometers uniform and comparable, it is defirable that mercury, fo excellently adapted for this purpofe, fhould be the only fluid ufed in the conftituted of them, more efpecially as a thermometer with mercury may be more eafily conftituted than any others. De Luc's *Récherches*, &c. vol. i. part ii. cap. 2. paffim.

Dr. Halley, though apprifed only of fome of the remarkable properties of mercury above recited, feems to have been the firft who fuggest'd the application of this fluid to the conftituted of thermometers. *Phil. Tranf. Abr.* vol. ii. p. 34.

Boerhaave (*Chem. i.* p. 720.) fays, thefe mercurial thermometers were firft contriv'd by Olaus Roemer; but the claims of Fahrenheit of Amfterdam, who gave an account of his invention to the Royal Society in 1724 (*Phil. Tranf. N° 381*, or *Abr.* vol. vii. p. 49.), have been generally allow'd. And though Prins and others, in England, Holland, France, and other countries, have made this inftrument as well as Fahrenheit, moft of the mercurial thermometers are graduated according to his fcale, and are call'd *Fahrenheit's* thermometers. Thefe are made of different lengths, and with fome variation in the form of the bulb, according to the purpofes for which they are defign'd. Inftead of the ball, ufed in the fpirit thermometer, a cone or cylinder is annex'd to the tube, which may be eafily enlarg'd or diminifh'd, and made of fuch a magnitude, that its capacity may have a certain and known proportion to that of the tube; and by this means feveral thermometers may be conftituted to the fame fcale: befides, the heat more eafily

THERMOMETER.

easily penetrates and reaches the inmost parts of the cylindric bulb, and causes the whole content to expand uniformly, and the mercury to rise almost immediately; whereas in thermometers with a spherical bulb it is seen first to fall, and then to rise. This phenomenon has been long since noticed both in Florentine and mercurial thermometers, when they are suddenly plunged into a heated liquor, the spirit of wine or mercury first descends, and then ascends; and when they are plunged into a cold fluid, the included liquor first ascends and then descends: this is the more remarkable in thermometers whose bulb is made of thick glass; and the reason of the phenomenon is obvious. The bulb of glass is sooner affected by the heat or cold applied to it than the included fluid; and as the glass expands by heat, the capacity of the bulb is enlarged, and the liquor descends in the tube, but being condensed by cold, and its capacity diminished, the liquor is pressed upwards in the tube: and both these effects continue till the heat and cold equally affect the included fluid. Hence it follows, that all the variations of ascent and descent, to which the spirit or mercury is subject in the thermometer, are only the difference of the rarefactions and condensations of glass, and of the contained fluid. Hist. Ac. Royal, 1705.

The cone, or cylinder, of the thermometer is made of glass of a moderate thickness, left, when the exhausted tube is hermetically sealed, its internal capacity should be diminished by the weight of the ambient atmosphere. When the mercury is thoroughly purged of its air and moisture by boiling, the thermometer is filled with a sufficient quantity of it; and before the tube is hermetically sealed, the air is wholly expelled by heating the mercury, so that it may be rarefied and ascend to the top of the tube. To the side of the tube is annexed a scale (see *fig. 4.*) which Fahrenheit divided into six hundred parts, beginning with that of the severe cold which he had observed in Iceland in 1709, or that produced by surrounding the bulb of the thermometer with a mixture of snow or beaten ice and sal ammoniac or sea-salt. This he apprehended to be the greatest degree of cold, and accordingly he marked this, as the beginning of his scale, with 0; the point at which mercury begins to boil, he conceived to shew the greatest degree of heat, and this he made the limit of his scale. The distance between these two points, he divided into six hundred equal parts or degrees; of which 32 reckoned from 0, indicates the degree of cold when snow or ice thaws naturally, or water begins to freeze, and this is called the *freezing point*: and he marked the heat of boiling water with 212, &c. In order more particularly to explain the divisions of this scale, and to shew how the dilatation and condensation of the mercury are estimated by it, we may observe that the bulb is supposed to contain, according to Boerhaave and Muschenbroek, 11124 parts of quicksilver, which stands at the lowest mark, or *gr.* 0, in an intense cold, &c. as above determined: if the bulb be immersed in snow or ice thawing naturally, or in water beginning to freeze, the quicksilver is dilated, and rises in the tube 32 of these 11124 parts; and therefore the space of the tube from *gr.* 0 to the freezing point *gr.* 32, is divided into thirty-two equal parts. When the thermometer is placed in water brought to a strong boiling at a middle state of the atmosphere in places near the level of the sea, when the mercury in the barometer stands at about 30 inches or a very little under it, the quicksilver is dilated 212 of these parts beyond its original bulk of 11124, so as now to possess in the bulb and tube together a space equal to 11336 such parts; and the space from *gr.* 32 to *gr.* 212, is divided into 180 equal parts or degrees of the thermometer;

which, if the tube be long enough, may be protracted as far as is convenient. It may extend well enough to *gr.* 600, and not much farther, for with a heat but little greater than that the mercury begins to boil.

Dr. Boerhaave, in one place, makes the number of parts into which the mercury in the bulb is supposed to be divided to be 10782 instead of 11124, and in another place states it at 11520, which Dr. Martine apprehends to be nearer the truth, or about 11790 parts; and he thinks the easiest and surest method is to fill the bulb and tube, without being solicitous about the bulk of the quicksilver, so that in freezing water, or melting ice, the mercury shall stand at a convenient height, which must be very nicely marked *gr.* 32; and then as accurately to observe where it stands when dilated by the heat of boiling water to *gr.* 212. The intermediate space is then divided into 180 degrees, which scale may be protracted upwards or downwards as far as we shall judge convenient. See *Fixed Points of THERMOMETERS.*

In the above method of graduating the scale, the bore of the tube is supposed to be perfectly cylindric, which cannot always be obtained. But though it be tapering or somewhat unequal, it is easy to manage that matter, in the manner proposed by the abbé Nollet (*Leçons de Phys. Exp. tom. iv. p. 376.*) by making a small portion of the quicksilver, *e. g.* as much as fills up an inch or half an inch, slide backward and forward in the tube; and thus to find the proportions of all its inequalities, and from thence to adjust the divisions to a scale of the most perfect equality. See *Observations on the Construction of THERMOMETERS.*

Other thermometers of a similar construction have been accommodated to common use, the scale of which is only a part of that above described. They have been made of a small size and portable form, and the tube with its annexed scale has been enclosed in another thicker glass hermetically sealed, in order to preserve it from injury. Mr. Ramsden, at the desire and for the use of Mr. Hunter in his experiments on the heat of animals and vegetables, constructed very small thermometers, six or seven inches long, and not above two twelfths of an inch thick in the stem; having the external diameter very little larger than that of the stem, on which was marked the freezing point. The stem was embraced by a small ivory scale, so as to slide upon it easily, and retain any position. Upon the hollow surface of this scale were marked the degrees which were seen through the stem. *Phil. Transf. vol. lxxviii. part i. p. 8.*

Several varieties of thermometers are constructed for philosophical purposes. For comprehending the whole range of thermometrical temperature from the most intense artificial cold to the boiling point of mercury, it is necessary to be provided with a very long tube; but for most chemical purposes, it need only be graduated to about ten degrees above the boiling point, which will reach the temperature of most saline solutions when boiling. For experiments in intense cold, a spirit thermometer should be graduated about 100 degrees below 0, and the lower extremity of the scale should be at some distance from the bulb, that the temperature may be observed without lifting the bulb out of any deep vessel that may contain the freezing mixture. The most delicate and sensible thermometers are made with a very small bulb, scarcely larger than the stem, and a tube of an extremely narrow bore, not larger than a horse-hair. For chemical purposes also, the scale should either be scratched on the glass itself, or, as this is difficult to be seen in a common light, an ivory scale should be attached without reaching so low as the bulb, that the latter may be safely immersed in acid or corrosive liquors.

THERMOMETER.

In 1733, M. de l'Isle of Peterburg constructed a *mercurial* thermometer (see *fig. 4.*) on the principles of Reaumur's *spirit* thermometer. In his thermometer, the whole bulk of quicksilver, when immersed in boiling water, is conceived to be divided into 10,000, or rather 100,000 parts; and from this one fixed point, the various degrees of heat, either above or below it, are marked in these parts on the tube or scale, by the various expansion or contraction of the quicksilver in all the imaginable variety of heat. Dr. Martine apprehends it would have been better if M. de l'Isle had made the integer of 100,000 parts, or fixed point at freezing water, and from thence computed the dilatations or condensations of the quicksilver in those parts. All the common observations of the weather, &c. would have been expressed by numbers increasing as the heat increased, which is the more natural way; nor would there have been any great incongruity, or inconvenience, in expressing, after the manner of Reaumur, the few observations that occur below simple freezing by numbers of contraction below *gr. 0.* or 100,000. However, in practice, it will not be very easy to determine exactly all the divisions from the alteration of the bulk of the contained fluid. And besides, as glass itself is dilated by heat, though in a less proportion than quicksilver, so that it is only the excess of the dilatation of the contained fluid above that of the glass that is observable; if different kinds of glass be differently affected by a given degree of heat, this will make a seeming difference in the dilatation of the quicksilver in the thermometers, constructed in the Newtonian method, either by M. de Reaumur's or M. de l'Isle's rules. Accordingly, it has been found, that the quicksilver in thermometers, constructed in M. de l'Isle's way, has stood at different degrees of the scale when immersed in thawing snow. In some it was at *gr. 154.* in others at 156, and in another at 158: and it appears by M. de l'Isle's own account, that his thermometers disagree considerably from one another. *Celsius's* thermometer has been chiefly used in Sweden, and hence it has been called the *Swedisch* thermometer. The French chemists have lately adopted it, under the name of *centigrade* thermometer. See *Fixed Points of THERMOMETERS*, and the table at the close of this article.

THERMOMETER, Metalline, is a name given to a machine composed of two metals, which, whilst it indicates the variations of cold and heat, serves to correct the errors that result from hence in the construction of pendulum clocks. Instruments of this kind have been contrived by Graham, Le Roy, in 1738, Ellicot, Harrison, &c. See *Compound PENDULUM*.

We have also an account of instruments of this kind invented by Mortimer, Frothingham, and Fitzgerald, in the *Phil. Transf.* vol. xlv. p. 689, vol. xlv. p. 129, and vol. li. p. 823; to which we must refer for a particular description of each, illustrated by figures.

M. de Luc has likewise described two thermometers of metal, which he uses for correcting the effects of heat upon a barometer, and an hygrometer of his construction connected with them. In one of these, a strong rod of well-hardened brass, supports upon an edge, at a convenient distance from the centre of motion, a lever, which holds the scale of the barometer suspended, and makes it rise or fall by the dilatation or condensation of the brass rod, as the quicksilver rises or falls in the barometer, by the corresponding variations of heat. This scale of the barometer, when it moves, draws or loosens a thread of silk-grafs, which goes over a small pulley placed upon the same axis with a much larger one, to which the scale of the hygrometer is hung likewise by a similar thread, which thus varies, by the proportion of the diameters of the pulleys, as the heat makes

VOL. XXXV.

the quicksilver in the hygrometer vary. This instrument is convenient for meteorological observations: because it saves one observation and two corrections for the heat; but it is necessary from time to time to correct an irregularity in it, which is easily perceived by means of an index, carried by the moveable scales of the two instruments, which, going over immovable scales of the same sort, shews their difference of height. When this difference is no longer conformable to the indication of the thermometer, it is easily rectified by turning small pegs, on which is twisted the thread of silk-grafs, which serves for the suspension of the scales. The irregularity just mentioned consists in this, that when the heat, after having varied, returns to the same point of the quicksilver thermometer, the metallic thermometer does not return to it exactly, but varies nearly in the following manner: during the summer, the latter gains constantly on the former, *i. e.* amidst its variations, it always preserves a small part of the lengthening, which is at that time its ordinary state. In winter, on the contrary, it becomes insensibly a little too short. The other metallic thermometer, which is more curious than useful, on account of its greater irregularity, consists of a rod of lead, which, communicating by a thread of silk-grafs with a small pulley fixed to the same axis with a greater one, conducts, by means of another pulley, a needle through whose axis, which is bored, passes another axis that carries the needle of a pulley barometer. Thus this instrument marks the heat and weight of the air upon two concentric circles, by means of two needles turning upon the same centre, as in clocks; besides which, the needle of the thermometer points out upon a third circle the correction for the heat, to be made on the barometer. See *Phil. Transf.* vol. lxxviii. part i. p. 437, &c.

THERMOMETERS, Oil. To this class belongs sir Isaac Newton's thermometer, constructed in 1701, with linseed oil instead of spirit of wine. This liquor has the advantage of being sufficiently homogeneous, and capable of a considerable rarefaction, not less than fifteen times greater than that of spirit of wine. It has not been observed to freeze even in very great colds, and it is able to bear a great heat, about four times that of water, without boiling. With these advantages it was made use of by sir Isaac Newton, who discovered by it the comparative degree of heat for boiling water, melting wax, boiling spirit of wine, and melting tin; beyond which it does not appear that this thermometer was applied. The method he used for adjusting the scale of this oil-thermometer was as follows: supposing the bulb, when immersed in thawing snow, to contain 10,000 parts, he found the oil expanded by the heat of the human body so as to take up one thirty-ninth more space, or 10256 such parts; and by the heat of water boiling strongly, 10725; and by the heat of melting tin, 11516. So that, reckoning the freezing point as a common limit between heat and cold, he began his scale there, marking it *gr. 0.* and the heat of the human body he made *gr. 12*; and, consequently, the degrees of heat being proportional to the degrees of rarefaction, or 10256 : 10725, *i. e.* 256 : 725 :: 12 : 34, the heat of boiling water was expressed by *gr. 34* = $\frac{725 \times 12}{256}$; and that

of the melting tin by *gr. 72.* *Phil. Transf.* No. 270, or *Abr.* vol. iv. part ii. p. 3.

Although in this graduation sir Isaac Newton does not specify any degree of cold below that of freezing water, yet it would be easy to protract his scale downward below *gr. 0.* or the freezing point, and thus to adapt it for estimating greater degrees of cold, like other thermometers. But there is another insuperable inconvenience that attends all

THERMOMETER.

thermometers made with oil, or any other viscid liquor, *viz.* that such a liquor adheres too much to the sides of the tube. In a sudden cold or fall of the oil, much of it sticks by the way, and only sinks gradually afterwards, so that at first the surface appears really lower than the present temperature requires. And besides, as at all times some of the oil must continue to stick and moisten the inside of the tube, in different degrees of heat and cold, the oil, becoming alternately more or less viscid, will adhere sometimes more and sometimes less; and will, therefore, inevitably disturb the regularity and uniformity of the thermometer. Martine's Essays, Ess. iii.

THERMOMETERS, Fixed Points of. Various methods have been proposed by various authors, for finding a fixed point, or degree, of heat and cold, from which to reckon the other degrees, and adjust the scale; so that observations made at the same or different times, in different places, might be compared together. For want of this, notwithstanding all the numerous registers of the weather, &c. that have been kept and published by different authors, we are much at a loss to determine the comparative differences of heat and cold in different countries and climates, and the result of many other observations. If all the weather-glasses in the world had been made according to one determined scale, these inconveniences and uncertainties would have been prevented; which, indeed, are now unavoidable, and must still continue so, till all agree to graduate their thermometers in the same manner, or at least determine some fixed or unalterable points of heat, to which all the different scales of those instruments may be reduced. The honourable Mr. Boyle was very sensible of this inconvenience, and much laments it; and he proposed the freezing of the essential oil of aniseeds, as a term of heat and cold that might be of use in making and judging of thermometers, and so to graduate them from this point according to the proportional dilatations or contractions of the included spirits. He mentioned also the coldness requisite to begin the congelation of distilled water as another fixed term that might be adopted; for he was persuaded, that among the ordinary waters, some were apt to freeze more easily than others. But he was deterred from prosecuting this scheme of fixing a standard for making and graduating all thermometers in the same way. Experiments, &c. on cold, in his works abridged by Shaw, vol. i. p. 579.

Dr. Halley (Phil. Trans. Abr. vol. ii. p. 36.) seems to have been fully apprized of the bad effects of the indefinite method of constructing thermometers, and wished to have them adjusted to some determined points. What he seems to prefer for this purpose is the degree of temperature which is found in subterranean places, where the heat in summer and cold in winter appears to have no influence. But this degree of temperature is shewn by Dr. Martine to be a term for the universal construction of thermometers, both inconvenient, as it cannot be easily ascertained; and a precarious one, as the difference of soils and depths may occasion a considerable variation. Another term of heat which he thought might be of use in a general graduation of thermometers, is that of boiling spirit of wine that has been highly rectified: but a much more convenient term of heat, though less insisted on by Dr. Halley, is that of boiling water. The first trace that occurs of the method of actually applying fixed points or terms to the thermometer, and of graduating it, so that the unequal divisions of it might correspond to equal degrees of heat, is the project of Renaldinus, professor, of Padua, in 1694: it is thus described in the Acta Erud. Lips. "Take a slender tube, about four palms long, with a ball fastened to the

fame; pour into it spirit of wine, enough just to fill the ball, when surrounded with ice, and not a drop over: in this state, seal the orifice of the tube hermetically, and provide twelve vessels, each capable of containing a pound of water, and somewhat more; and into the first pour eleven ounces of cold water, into the second ten ounces, into the third nine, &c.: this done, immerge the thermometer in the first vessel, and pour into it one ounce of hot water, observing how high the spirit rises in the tube, and noting the point with unity: then remove the thermometer into the second vessel, into which are to be poured two ounces of hot water, and note the place the spirit rises to with 2. By thus proceeding till the whole pound of water is spent, the instrument will be found divided into twelve parts denoting so many terms or degrees of heat; so that at 2 the heat is double to that at 1, at 3, triple, &c."

But this method, though plausible, Wolfius shews, is deceitful, and is built on false suppositions; for it takes for granted, that we have one degree of heat, by adding one ounce of hot to eleven of cold water; two degrees, by adding two ounces to ten, &c.: it supposes, also, that a single degree of heat acts on the spirit of wine in the ball with a single force; a double with a double force, &c. lastly, it supposes, that if the effect be produced in the thermometer by the heat of the ambient air, which is here produced by the hot water, the air has the same degree of heat with the water.

Soon after this project of Renaldinus, *viz.* in 1701, Sir Isaac Newton constructed his *oil* thermometer, and fixed the base or lowest fixed point of his scale at the temperature of thawing snow, and twelve at that of the human body, &c. in the manner explained under the article *Oil THERMOMETER.*

M. de Luc observes, that the second term of his scale should have been at a greater distance from the first, and that the heat of boiling water would have answered this purpose better than that of the human body.

In 1702, M. Amontons contrived his *universal* thermometer, the scale of which was graduated in the following manner. He chose for the first term the weight that counterbalanced the air included in his thermometer, when it was heated by boiling water: and in this state he so adjusted the quantity of mercury contained in it, till the sum of its height in the tube, and of its height in the barometer at the moment of observation, was equal to seventy-three inches. Fixing this number at the point to which the mercury in the tube rose by plunging it into boiling water, it is evident, that, if the barometer at this time was twenty-eight inches, the height of the column of mercury in the thermometer above the level of that in the ball was forty-five inches; but if the height of the barometer was less by a certain quantity, the column of the thermometer ought to be greater by the same quantity, and reciprocally. He formed his scale on the supposition that the weight of the atmosphere was always equal to that of a column of mercury of twenty-eight inches, and divided it into inches from the point 73 downwards, marking the divisions with 72, 71, 70, &c. and he subdivided the inches into lines.

But as the weight of the atmosphere is variable, the barometer must be observed at the same time with the thermometer, that the number indicated by this last instrument may be properly corrected, by adding or subtracting the quantity of which the mercury is below or above twenty-eight inches in the barometer. In this scale, then, the freezing point is at 51½ inches, corresponding to *gr.* 32 of Fahrenheit, and the heat of boiling water at 73 inches,

THERMOMETER.

inches, answering to *gr.* 212 of Fahrenheit's: and thus they may be easily compared together.

The fixed points of Fahrenheit's thermometer, which is generally used in Great Britain, (as we have already observed under *Mercurial THERMOMETER*,) are the congelation produced by sal ammoniac and the heat of boiling water. The interval between these points is divided into 212 equal parts; the first of these points is marked 0, 32 degrees below the freezing point, and the other 212; the distance of course between the freezing and boiling points being 180. The reason why Fahrenheit fixed his scale so far below the water-freezing point was founded on an erroneous hypothesis relative to the real *zero* or point of absolute privation of heat; nevertheless it has this advantage, that the distinction between the positive and negative terms, or those which express degrees above or below the *zero*, much less frequently occurs in any experiments, and scarcely ever in the register of natural cold in temperate climates, by which many accidental errors are avoided. Reaumur, in his thermometer, the construction of which he published in 1730, and which is generally used in France and other parts of the continent, begins his scale at an artificial congelation of water in warm weather, which, as he uses large bulbs for his glasses, gives the freezing point much higher than it should be, and at boiling water he marks *gr.* 80, (the distance between both points being 80,) which point Dr. Martine apprehends to be more vague and uncertain than his freezing point. The spirit in the thermometer, he observes, is absolutely incapable of such a great heat as Reaumur ascribed to it, and that not by a small or trifling difference. He finds, that highly rectified spirit of wine cannot be heated beyond *gr.* 175 in Fahrenheit's thermometer, while boiling water raises the quicksilver 37 degrees higher; and common brandy was able to conceive a heat no greater than about *gr.* 190. So far, he concludes, was Reaumur in the wrong, when he thought that all spirits, weak and strong, immersed in boiling water, received a given degree of heat, and that equal to the heat of the surrounding water. He supposes his standard heat could take a heat only of about *gr.* 180; less by 32 degrees than what he reckoned. In order to determine the correspondence of his scale with that of Fahrenheit, it is to be considered that his boiling-water heat is really only the boiling heat of weakened spirit of wine, coinciding nearly, as Dr. Martine apprehends, with Fahrenheit's *gr.* 180. And as his *gr.* 10 $\frac{1}{2}$ is the constant heat of the cave of the observatory at Paris, or Fahrenheit's *gr.* 53, he thence finds his freezing point, instead of answering just to *gr.* 32, to be something above *gr.* 34.

The thermometer of M. de l'Isle, of which he presented an account to the Academy of Sciences at Petersburg in 1733, has only one fixed point, which is the heat of boiling water, and, contrary to the common order, the several degrees are marked downwards from this point or *zero*, according to the condensations of the contained quicksilver, and consequently by numbers increasing as the heat decreases to 150, the freezing point. In order to determine the extent of the degrees of this scale, M. de l'Isle first weighed the empty tube, and then weighed it full of mercury; and the difference of these two weights gave him that of the mercury. He then exposed the thermometer to the heat of boiling water, and took care to preserve the mercury, which this increase of heat forced out of it; this he accurately weighed, and deducting its weight from the total weight of the mercury, he made the remainder, or that which was left in the thermometer, equal to 10000: he then found by calculation how many 10000 parts of this

residue that forced out of the tube contained, and these parts formed the divisions of the scale from the point, determined by the condensation of the mercury to the same point at which it stood before it was plunged in boiling water, to the upper end of the tube; and these divisions formed the extent of the degrees of M. de l'Isle's scale. According to his standards, the freezing point, says Dr. Martine, is near to his *gr.* 150, corresponding to Fahrenheit's *gr.* 32, by which means they may be compared; but M. Ducrest says, that this point ought to be marked at least at *gr.* 154.

M. Ducrest, in his spirit thermometer, constructed in 1740, made use of two fixed points; the first, or 0, indicated the temperature of the earth, and was marked on his scale in the cave of the Royal Observatory at Paris; and the other was the heat of boiling water, which the spirit in his thermometer was made to endure, by leaving the upper part of the tube full of air. He divided the interval between these points into 100 equal parts; calling the divisions upwards degrees of heat, and those below 0 degrees of cold.

He afterwards regulated his thermometer by the degree of cold indicated by melting ice, which he found to be 10 $\frac{3}{4}$. In Celsius's, or the centigrade thermometer, the freezing point, like that of Reaumur's, was 0, the boiling point at 100, and the distance between both 100. See the table at the close of the article.

The Florentine thermometers made and used by the members of the famous academy *del' Cimento*, being some of the first instruments of the sort, were vaguely graduated, some of them having many more degrees than others; but those of their most common graduation were of two sorts; in one sort the freezing point, determined by the degree at which the spirit stood in the ordinary cold of ice or snow (probably in a thawing state), and coinciding with *gr.* 32 of Fahrenheit, fell at *gr.* 20; and in the other sort at *gr.* 13 $\frac{3}{4}$; and the natural heat of the viscera of cows and deer, &c. raised the spirit in the latter, or less sort, to about *gr.* 40, coinciding with their summer heat, and nearly with *gr.* 102 in Fahrenheit's, and in their other long thermometer, the spirit, when exposed to the great midsummer heat in their country, rose to the point at which they marked *gr.* 80. The freezing point of one was 20, the boiling point 174, and the distance between both was 154: in the other the freezing point was 13 $\frac{1}{2}$, the boiling point 81 $\frac{1}{2}$, and the distance 68 $\frac{1}{2}$.

In the Parisian thermometer, or the ancient thermometer of the Academy of Sciences, the freezing point was at 25, the boiling point at 239, and the distance between both 214.

In the thermometer of the observatory at Paris, made of spirit of wine by M. de la Hire, the spirit always stands at *gr.* 48, in the cave of the observatory, corresponding to *gr.* 53 in Fahrenheit's; and his *gr.* 28 corresponded with 51 inches six lines in Amontons's thermometer, and consequently with the freezing point, or *gr.* 32 of Fahrenheit's. This thermometer of De la Hire, which stood in the observatory of Paris above 60 years, seems to have been graduated thus; the freezing point 28, the boiling point 199 $\frac{1}{2}$, and the distance between both 171 $\frac{1}{2}$. In Amontons's thermometer the freezing point was 51 $\frac{1}{2}$, the boiling point 73, and the distance between them 21 $\frac{1}{2}$.

In the thermometer of Poleni, made after the manner of Amontons's, but with less mercury, 47 inches corresponded, according to Dr. Martine, with 51 in that of Amontons's, and 53 with 59 $\frac{1}{2}$. It was graduated thus; the freezing point at 47 $\frac{1}{2}$, the boiling point at 62 $\frac{1}{2}$, and

THERMOMETER.

the distance between them $15\frac{1}{2}$. In Crucequius's, the freezing point was 1070, the boiling point 1510, and the distance 440.

In the ancient standard thermometer of the Royal Society, after which thermometers were for a long time constructed in England, Dr. Martine found that *gr.* $34\frac{1}{2}$, answered to *gr.* 64 in Fahrenheit's, and *gr.* 0 to 89 or 88. From that point the numeration ascended and descended thus; the freezing point was $73\frac{1}{2}$, the boiling point $141\frac{1}{2}$, and the distance between them $215\frac{1}{2}$. In sir Isaac Newton's, the freezing point was 0, the boiling point 34, and the distance 34.

In the thermometers graduated for adjusting the degrees of heat proper for exotic plants, &c. in stoves and green houses, the middle temperature of the air is marked at *gr.* 0, and the degrees of heat and cold are numbered both above and below. Many of these are made on no regular and fixed principles. But in that formerly much used, called Fowler's regulator, the spirit fell, in melting snow, to about *gr.* 34 under 0; and Dr. Martine found, that his *gr.* 16 above 0, coincided with nearly *gr.* 64 of Fahrenheit. His 0 seems to have coincided with about the 53d or 54th degree of Fahrenheit's, and from that point the numeration ascended and descended thus; the freezing point 34, the boiling point $250\frac{1}{2}$, and the distance between them $284\frac{1}{2}$.

Dr. Hales (Statistical Essays, vol. i. p. 58.) in his thermometer made with spirit of wine, and used in experiments on vegetation, began his scale with the lowest degree of freezing, or *gr.* 32 of Fahrenheit, and carried it up to *gr.* 100, which he marked where the spirit stood when the ball was heated in hot water, on which wax swimming first began to coagulate, and this point Dr. Martine found to correspond with *gr.* 142 of Fahrenheit. But by experience Hales's *gr.* 100 falls considerably above our *gr.* 142. According to others, his freezing point was 0, his boiling point was 163, and the distance of course 163.

In the Edinburgh thermometer, made with spirit of wine, and used in the meteorological observations published in the Medical Essays, the scale is divided into inches and tenths. In melting snow the spirit stood at $8\frac{2}{5}$, and the heat of the human skin raised to $22\frac{2}{5}$. Dr. Martine found, that the heat of the person who graduated it was *gr.* 97 of Fahrenheit. It seems to have been graduated thus; the freezing point $8\frac{1}{2}$, the boiling point 47, and the distance between them $38\frac{1}{2}$.

As it is often of use to compare different thermometers, in order to judge of the result of former observations, we have annexed from Dr. Martine's Essays, the table by which he compared fifteen different thermometers. See *Plate XVI. Pneumatics, fig. 4.* See also the table at the close of this article.

There is a thermometer which was formerly much used in London, called the thermometer of Lyons, because M. Cristin brought it there into use, which is made of mercury: the freezing point is marked *gr.* 0, and the interval from that point to the heat of boiling water is divided into 100 equal degrees.

From the above abstract of the history of the construction of thermometers, it appears that freezing and boiling water have furnished the distinguishing points that have been marked upon almost all thermometers. The inferior fixed point is that of freezing, which some have determined by the freezing of water, and others by the melting of ice; and though the difference between these two temperatures is not commonly very considerable, yet it is not invariable.

It is now well known, that all, or almost all bodies, by changing from a fluid to a solid state; or from the state of an elastic to that of an unelastic fluid, generate heat; and that cold is produced by the contrary process.

In order to obtain this fixed point or limit, melting ice, or ice powdered and mixed with water, will produce the same temperature. And though there may be some trifling difference between the temperature of ice disposed to melt, and that of melted ice or the water produced by it; this difference, however, has no sensible effect on the thermometer; consequently, the temperature of water successively produced by ice, and accumulated in its interstices, or from powdered ice mixed with the water which is produced by it in melting, affords, as De Luc observes, a fixed point, which is easily obtained, and which should be adopted in the construction of all thermometers.

The superior fixed point of almost all thermometers, is the heat of boiling water; but this point cannot be considered as fixed, unless the heat be produced by the same degree of boiling, and under the same weight of the atmosphere. With regard to the first circumstance, it is observed, that water, when it begins to boil, has not attained to its greatest degree of heat, which is known by its bubbling or foaming from the bottom of the vessel, and over the whole surface of the water, with the greatest violence which it is capable of acquiring; and in this state the water discovers an augmentation of heat more than one degree above the heat it had when it began to boil. The temperature of water which boils with vehemence should, therefore, be the standard of the fixed point of thermometers: nevertheless it is to be considered farther, that this degree of heat with which water violently boils, is invariably the same, only under a given pressure of the atmosphere; but if the pressure be diminished or increased, the boiling heat is diminished or increased. It is well known that water, placed under the exhausted receiver of an air-pump, will be converted into steam with a degree of heat far inferior to that which is necessary to its boiling in the open air; and under the pressure of its own vapour, confined in Papin's digester, it is said to sustain a degree of heat, without boiling, far exceeding that which, in the open air, would convert it into steam. Hence it follows that, in climates where the pressure of the atmosphere is liable to considerable change, the heat of boiling water, in open air, will be different at different times. Consequently thermometers, made in different states of the barometer, will disagree; unless allowance has been made for the effect of the variation of the barometer upon accurate principles. That the heat of boiling was variable, according to the pressure of the atmosphere, seems to have been known to Fahrenheit as early as the year 1724. See *Phil. Transf. N^o 385.*

Some time after this period, Messrs. le Monnier and Cassigni (*Mem. de l'Acad. des Sc. for 1740*) made some decisive observations, in order to shew that this quantity was very considerable.

M. de Luc, in 1762, made a much more complete series of experiments, which he has described and reduced into a system in his *Récherches sur les Mod. de l'Atmosphère*, vol. i. p. 382, &c. vol. ii. p. 338, &c. and these have been since verified by sir George Shuckburgh, in 1775 and 1778. See *Phil. Transf. vol. lxxix. part ii. p. 362, &c.*

M. de Luc fixes the boiling point of his thermometer when the barometer is at 27 Paris, or 28.75 English inches, that being its mean height at Geneva. He divides the fundamental interval, *i. e.* the whole extent of the scale, between melting ice and boiling water, after the French manner, into eighty equal parts; and by a great number of experiments

THERMOMETER.

periments on the heat of boiling water, at different heights above the level of the sea, he hath found, that the height of his thermometer, plunged in boiling water, may be expressed, in all states of the barometer, by the following formula, *viz.*

$$\frac{99}{200000} \log. y - a = T : \text{ in which } y \text{ denotes the height of}$$

the barometer in sixteenths of a Parisian line, T the height of a thermometer, plunged in boiling water, above melting ice, in hundredths of a degree of his scale; and *a* the constant number 10387.

By logarithms he always means the tabular or Briggsian logarithms, and considers the seven figures given by the tables, besides the index, as integral figures, *i. e.* he considers the eighth figure of the logarithm as standing in the place of units. But as it is more usual with mathematicians, and, in general, more convenient, to consider all the figures after the index as decimals, the number which M. de

Luc expresses by $\frac{99}{200000} \log. y$, would in that case be

$$\frac{99 \times 100}{2} \log. y; \text{ or } 99 \times 50 \log. y. \text{ However, in the}$$

sequel, M. de Luc's notation is retained.

Now if care were taken by the above formula, or in any other way, to adjust the boiling point to the main height of the barometer in every country, the instruments of the same country would always be consistent; but those of different countries would still disagree; that is, they would express the same temperature differently, though their similar intervals should be similarly divided; for in every scale, the number of degrees above or below melting ice, by which any given temperature is expressed, will be as the value of each degree inversely; that is, if each be a given part of the fundamental interval, as the value of the fundamental interval inversely; but if the degrees of different scales be different parts of the fundamental intervals, as the value of the fundamental interval inversely, and the number of degrees contained in it directly.

In order, therefore, to compare the thermometers of different countries, the proportions of their fundamental intervals to each other must be ascertained, or we must have some means of finding, upon one scale, the place of the boiling point of another. For this purpose, a general solution is requisite of the following problem, *viz.* the fundamental interval being given for a given height of the barometer, to find the fundamental interval for any other given height of the barometer. The solution is furnished by M. de Luc's researches; and his formula, above given, is reduced to English measures, and adapted to English instruments, by Dr. Horsley. As the subject is curious and important, we shall subjoin the process he has pursued for this purpose. It is but seldom that the barometer in this country stands so low as 27 Paris inches. Its main height upon the plain country about London is near 30 English inches. It may, therefore, be proper for the London workmen to fix their boiling point when the barometer is at 30 inches. Fahrenheit's division of the scale, which makes 180 degrees between melting ice and boiling water, and places the point 0 at the 32d degree below melting ice, may be retained: and the thermometer thus constructed is called by Dr. Horsley, Bird's Fahrenheit, because Mr. Bird, he apprehends, is the first workman who took the pains to attend to the state of the barometer in making thermometers, and has always fixed the boiling point when his barometer has stood at 30 inches.

T, then, being put for the height of a thermometer

plunged in boiling water, above melting ice, in 100ths of a degree of De Luc's scale, in any given state of the barometer; let \ominus denote the same height in 100ths of a degree of Bird's Fahrenheit; put *y* for the height of the barometer, in 16ths of a Paris line; *v*, for its height in Paris lines; *x*, in 10ths of a Paris inch; *z*, in 10ths of an English inch; and for 10387 put *a*; for 16, *b*; for 10, *c*; for 12, *d*; and let E and F represent numbers expressing the proportion of the English foot to the French foot.

M. de Luc hath found that, whatever be the value of *y*,

$$\frac{99}{200000} \log. y - a = T. \text{ But } \log. y = \log. v + \log. b;$$

$$\text{and } \log. v = \log. x + \log. d - \log. c; \text{ and } \log. x = \log. z + \log. E - \log. F; \text{ therefore } \log. y = \log. z + \log.$$

$$E + \log. d + \log. b - \log. F - \log. c; \text{ and } \frac{99}{200000} \log.$$

$$z + \frac{99}{200000} \log. E + \log. d + \log. b - \log. F - \log. c$$

$$- a = T. \text{ But } \frac{99}{200000} \log. E + \log. d + \log. b - \log.$$

$$F - \log. c - a = -4171.55; \text{ the French foot being}$$

$$\text{to the English as 2.1315 to 2. Therefore } \frac{99}{200000} \log. z$$

$$- 4171.55 = T; \text{ and } \frac{99}{2000000} \log. z - 41.7155 =$$

$$\frac{T}{100} = \text{the height of the thermometer, plunged in boiling}$$

water, above melting ice, in degrees of De Luc's scale, when the height of the barometer in tenths of an English

inch, is *z*. For *z* write 300: then $\frac{T}{100} = 80.902$; which

is therefore the height of the thermometer, in boiling water, above melting ice, in degrees of De Luc's scale, when the barometer is at 30 inches English. And in the same state of the barometer, the height of the thermometer plunged in boiling water, above melting ice, in degrees of Bird's Fahrenheit, or $\frac{\ominus}{100}$, is 180. Hence the numbers T and \ominus

are in the constant proportion of 809 and 1800, whatever be the value of *z*. For the change produced in the heat of boiling water, by any change of *z*, being always the same for both thermometers, the temperature expressed by T in parts of one scale is always the same, as \ominus ex-

presses in parts of the other; and therefore putting $\frac{1}{L}$

and $\frac{1}{B}$ for the values of the 100th part of a degree of the

scales of De Luc and Bird respectively, the fractions $\frac{T}{L}$,

$\frac{\ominus}{B}$ are always equal, and T, \ominus are in the constant propor-

tion of the invariable numbers L, B: consequently, when the proportion of T and \ominus is determined for any particular value of *z*, it is found generally for all: consequently T: \ominus

$$:: 809 : 1800. \text{ And } T = \frac{809}{1800} \ominus = \frac{899}{2000} \ominus \text{ very nearly}$$

in all values of *z*: and substituting this value for T in the equation

THERMOMETER.

equation exhibiting the relation between z and T , we have,

for the relation between z and Θ , $\frac{99}{20000000} \log. z -$

$41.7155 = \frac{899}{2000 \times 100} \Theta$: or, $\frac{99}{10000 \times 899} \log. z -$

$92.804 = \frac{\Theta}{100}$ = the height of the thermometer in boiling

water, above melting ice, in degrees of Bird's Fahrenheit, when the height of the barometer in tenths of an English inch, is z . And thus M. de Luc's formula, for the variation of the boiling point, is adapted to English instruments, and reduced to English measures of length.

For z write 287.7525, the length of 27 French inches in tenths of an English inch, and $\frac{\Theta}{100}$, the height of De Luc's

boiling point above melting ice, in degrees of Bird's Fahrenheit, comes out 177.989. Hence M. de Luc's boiling point falls upon 209.989 of Bird's scale, *i. e.* upon 210 very nearly, or infensibly more than two degrees below Bird's point of boiling. But as 899 is a troublesome divisor, the computation will be more easy and expeditious, by writing

for $\frac{11}{1000000} \log. z$, s . Then $s + \frac{1}{900} s - 92.804 =$

$\frac{\Theta}{100}$ very nearly. Upon these principles Dr. Horsley has

computed the table following, for finding the heights to which a good Bird's Fahrenheit will rise, when plunged in boiling water, in all states of the barometer, from 27 to 31 English inches; which will serve, among other uses, to direct instrument-makers in making a true allowance for the effect of the variation of the barometer, if they are obliged to finish a thermometer, when the barometer is above or below 30 inches; though it is best to fix the boiling point when the barometer is at the height prescribed.

Equation of the Boiling Point.

Barometer.	Equation.	Difference.
31.0	+ 1.57	0.78
30.5	+ 0.79	0.79
30.0	0.00	0.80
29.5	- 0.80	0.80
29.0	- 1.62	0.82
28.5	- 2.45	0.83
28.0	- 3.31	0.85
27.5	- 4.16	0.86
27.0	- 5.04	0.88

The numbers in the first column of this table express heights of the quicksilver in the barometer in English inches and decimal parts: the second column shews the equation to be applied, according to the sign prefixed, to 212° of Bird's Fahrenheit to find the true boiling point for every such state of the barometer. The boiling point for all intermediate states of the barometer may be had with sufficient accuracy by taking proportional parts, by means of the third column of differences of the equations. (See Phil. Transf. vol. lxiv. part i. art. 30. See also an excellent paper on this subject by Dr. Maskelyne, in the Phil. Transf. vol. lxiv. part i. art. 20.) In the following table we have the result of fifteen different observations

made by Sir George Shuckburgh (*ubi supra*) compared with the result of M. de Luc's rules.

Height of the Barometer reduced to the same Temperature of 50° .	Mean Boiling Point by Observation.	Boiling Point by De Luc's Rules.
Inch.	Deg.	Deg.

31.0	+ 1.69	.84	+ 1.57	.78

The Royal Society, fully apprized of the importance of adjusting the fixed points of thermometers, appointed a committee of seven gentlemen to consider of the best method for this purpose; and their report is published in the Phil. Transf. vol. lxvii. part ii. art. 37. From a variety of experiments and observations, relating to this subject, the committee have deduced the following practical rules, which they recommend in adjusting the fixed points of thermometers. The most accurate way of adjusting the boiling point is, not to dip the thermometer into the water, but to expose it only to the steam, in a vessel closed up in the manner represented in *Plate XVI. Pneumatics, fig. 6.* where *ABba* is the vessel containing the boiling water, *Dd* the cover, *E* a chimney made in the cover intended to carry off the steam, and *Mm* the thermometer passed through a hole in the cover. In the pursuit of this method the following particulars must be regarded: the boiling point must be adjusted when the barometer is at 29.8 inches; unless the operator corrects the observed point in the manner

THERMOMETER.

manner directed in the sequel of this article. The ball of the thermometer must be placed at such a depth within the pot, that the boiling point may rise very little above the cover; and the surface of the water in the pot should be at least one or two inches below the bottom of the ball. Care must be taken to stop up the hole in the cover through which the tube is inserted, and to make the cover fit pretty close, so that no air shall enter into the pot that way, and that not much steam may escape. A piece of thin flat tin-plate must also be laid on the mouth of the chimney, so as to leave no more passage than what is sufficient to carry off the steam.

If the artist pleases, he may tie each corner of this plate by a string to prongs fixed to the chimney, and standing on a level with the plate, as it will be thus always kept in its place.

Fig. 7. is a perspective view of the chimney and tin-plate; ABCD is the plate, E the chimney, Ff, Gg, Mm, and Nn, the prongs fastened to the chimney, to which the four corners of the plate are to be tied by the strings AF, BG, CM, and DN; the ends F, G, M, and N, of the prongs must be on a level with the plate, and the strings should not be stretched tight. The chimney ought not to be less than half a square inch in area, and not less than two or three inches in length. The cover should be made to take on and off easily, and a ring of woollen cloth may be placed under it, so as to lie between it and the top of the pot. The hole in the cover may be stopped up by a cork, with a hole bored through it, big enough to receive the tube, and then cut into two, parallel to the length of the hole. Another method, more convenient in use, but not so easily made, is represented in fig. 8. which exhibits a perspective view of the apparatus: Aa is the cover, H the hole through which the thermometer is passed, Bb a flat piece of brass fixed upon the cover, and DdEe a sliding piece of brass, made so as either to cover the hole H, or to leave it uncovered, as in the figure, and to be tightened in either position by the screw s sliding in the slit Mm; also in the edge Dd, to enclose the tube of the thermometer: pieces of woollen cloth should also be fastened to the edges Bb and Dd, and also to the bottom of the sliding-piece DdEe, unless that piece and the cover are made sufficiently flat to prevent the escape of the steam. In order to keep the thermometer suspended at the proper height, a clip may be used like that represented in fig. 9. which, by the screw s, must be made to embrace the tube tightly, and may rest on the cover.

Another method, which is rather more convenient, when the top of the tube of the thermometer is bent into a right angle, in the manner often practised at present for the sake of more conveniently fixing it to the scale, is represented in fig. 10.: GgFf is a plate of brass standing perpendicularly on the cover, and L/Nn a piece of brass bent at the bottom into the form of a loop, with a notch in it, so as to receive the tube of the thermometer, and to suffer the bent part to rest on the bottom of the loop; this piece must slide in a slit Kk, in the plate L/Nn, and be tightened at any height by the screw T.

Moreover, it is best to make the water boil pretty briskly, as otherwise the thermometer is apt to be a great while before it acquires its full heat, especially if the vessel is very deep; and the observer should wait at least one or two minutes after the thermometer appears to be stationary, before he concludes that it has acquired its full height.

Another way of adjusting the boiling point is to try it in a vessel of the same kind as the former, only with the water

rising a little way, viz. from one to three or four inches above the ball, taking care that the boiling point shall rise very little above the cover. In this method there is no need to cover the chimney with the tin-plate, and there is less need to make the cover fit close, unless to prevent the operator from being incommoded with the steam. The height of the barometer in this method is 29½ inches.

It will be convenient to have two or three pots of different depths for adjusting thermometers of different lengths. A third way of adjusting the boiling point is to wrap several folds of linen rags or flannel round the tube of the thermometer, and to try it in an open vessel, taking care to pour boiling water on the rags, in order to keep the quicksilver in the tube as nearly of the heat of boiling water as possible. In this method the barometer should be at 29.8 inches; the water should boil fast, and the thermometer should be held upright, with its ball two or three inches under water, and in that part of the vessel where the current of water ascends.

Whichever of these methods of adjusting the boiling point is used, it is not necessary to wait till the barometer is at the proper height, provided the operator will take care to correct the observed height according to the following table.

Height of the Barometer when the Boiling Point is adjusted according to the		Correction in 1000ths of the Interval between 32° and 212°	Height of the Barometer when the Boiling Point is adjusted according to the		Correction in 1000ths of the Interval between 32° and 212°

In using this table, seek the height of the barometer in the column answering to the method of adjusting the boiling point, the corresponding number in the third column shews how much the point of 212° must be placed above or below the observed point: e. gr. suppose the boiling point to be adjusted in them when the barometer is at 29 inches, and that the interval between the boiling and freezing points is 11 inches; the nearest number to 29 in the left-hand column is 29.03, and the corresponding number in the table is 7 higher, and therefore the mark of 212° must be placed higher than the observed point by $\frac{7}{1000}$ ths of the interval between boiling and freezing, i. e. by $\frac{11 \times 7}{1000}$, or .077

of an inch. This method of correcting the boiling point is not strictly just, unless the tube is of an equal bore in all its parts; but the tube is seldom so unequal as to cause any sensible error, where the whole correction is so small. The trouble of making the correction will be abridged by a diagonal scale, such as is represented in fig. 10.

Although it is of no great consequence what kind of water is used in adjusting the boiling point, so that it is not salt,

THERMOMETER.

salt, or, if it be hard, that it should be kept boiling at least ten minutes before it is used; yet the committee recommend, for the adjustment of thermometers intended for nice experiments, to employ rain or distilled water, and to perform the operation in steam.

It is observed, that though the boiling point be placed so much higher on some of the thermometers now made than on others, yet this does not produce any considerable error in the observations of the weather, at least in this climate; for an error of $1\frac{1}{2}^{\circ}$ in the position of the boiling point, will make an error only of half a degree in the position of 92° , and of not more than a quarter of a degree in the point of 62° .

It is only in nice experiments, or in trying the heat of hot liquors, that this error in the boiling point can be of much signification.

In adjusting the freezing, as well as the boiling point, the quicksilver in the tube ought to be kept of the same heat as that in the ball. When the freezing point is placed at a considerable distance from the ball, the pounded ice should be piled to such a height above the ball, that the error which can arise from the quicksilver in the remaining part of the tube, not being heated equally with that in the ball, shall be very small, or the observed point must be corrected on that account, according to the following table.

Heat of the Air.	Correction.
42°	.00087
52	.00174
62	.00261
72	.00348
82	.00435

The correction in this table is expressed in 1000th parts of the distance between the freezing point and the surface of the ice: *e. g.* if the freezing point stands seven inches above the surface of the ice, and the heat of the room is 62° , the point of 32° should be placed $7 \times .00261$, or $.018$ of an inch lower than the observed point. A diagonal scale will facilitate this correction.

The committee observe, that in trying the heat of liquors, care should be taken that the quicksilver in the tube of the thermometer be heated to the same degree as that in the ball; or if this cannot be done conveniently, the observed heat should be corrected on that account; for the manner of doing which, and a table calculated for this purpose, we must refer to their excellent report in the *Phil. Trans.* vol. lxxvii. part ii. art. 37.

Several experiments made by governor Hutchins, at Albany Fort, in Hudson's Bay, in 1782, in pursuance of a method suggested by Dr. Black and Mr. Cavendish, and for which he obtained Sir Godfrey Copley's medal from the Royal Society in 1783, have not only confirmed the observations before made, relative to the solid state into which quicksilver can be brought by cold, its metalline splendour and polish when smooth, its roughness and crystallization where the surface was unconfined, its malleability, softness, and dull sound when struck; but have also clearly demonstrated, that its point of congelation is no lower than -40° , or rather -39° , of Fahrenheit's scale; that it will bear, however, to be cooled a few degrees below that point, to which it jumps up again on beginning to congeal; and that its rapid descent in a thermometer, through many hundred of degrees, when it has once passed the above-mentioned

limit, proceeds merely from its great contraction in the act of freezing. See *Phil. Trans.* vol. lxxiii. part ii. art. 20, 21.

THERMOMETERS, Observations on the Construction of. It is absolutely necessary that those who would derive any advantage from these instruments, should agree in using the same liquor, and in determining, according to the same method, the two fundamental points. If they agree in these fixed points, it is of no great importance whether they divide the interval between them into a greater or less number of equal parts. The scale of Fahrenheit, in which the fundamental interval between 212° , the point of boiling water, and 32° , that of melting ice, is divided into 180 parts, should be retained in the northern countries, where Fahrenheit's thermometer is used: and the scale, in which the fundamental interval is divided into 80 parts, will serve for those countries where the thermometer of M. de Reaumur is adopted. But no inconvenience is to be apprehended from varying the scale for particular uses, provided care be taken to signify into what number of parts the fundamental interval is divided, and the point where 0 is placed.

With regard to the choice of tubes, it is most desirable to have them exactly cylindrical through their whole length. See *Mercurial THERMOMETER.*

The capillary tubes are preferable to others, because they require less bulbs, and they are also less brittle, and more sensible. Those of the most convenient size for common experiments are such as have their internal diameter about the fourth of a line: and those made of thin glass are better than others, as the rise and fall of the mercury may be more distinctly perceived. The length of nine inches will serve for all common occasions; but for particular purposes, the length both of the tubes and of the divisions should be adapted to the uses for which they are designed.

In determining the best size of the balls or bulbs, it has been usual to compare new tubes with such thermometers as are well proportioned. But M. Durand has proposed a formula for finding the proportion which the balls ought to bear to their respective tubes. With this view he expresses the length of the tube, measured in diameters of itself, by a ; the whole capacity of the ball and tube by c ; the capacity of the fundamental interval, expressed in the same parts with the whole capacity, by d ; the number of degrees of the fundamental interval by m ; the number of other degrees which the scale is to contain, besides those of the fundamental interval both above and below it, by n ; and the diameter of the ball measured in diameters of the tube by b : and $b =$

$$\sqrt[3]{\frac{2}{3} a \times \frac{c m}{d \times m + n}} - 1. \quad \text{For two cylinders having}$$

equal bases being as their heights, $m : n :: d : \frac{dn}{m}$, which is

the capacity of that part of the tube which exceeds the fundamental interval, to which adding d , that interval,

we have the total capacity of the tube $= \frac{dn}{m} + d$, or

$\frac{dn + dm}{m}$. Subtracting this from c , we shall have the

capacity of the ball $= c - \frac{dn + dm}{m} = \frac{cm - dm - dn}{m}$.

If this quantity be divided by the capacity of the tube, the quotient will shew how often the capacity of the ball contains that of the tube; and this quotient is $=$

THERMOMETER.

$\frac{cm - dm - dn}{dm + dn}$. Consequently the ball is equal to as many

cylinders having a diameters of the tube, for their respective height, and 1 diameter for the base, as are contained in this last quotient; and, therefore, its cylindric solidity expressed in the cylindric solidities of the tube will be $= a \times$

$\frac{cm - dm - dn}{dm + dn}$. But the diameter of this ball is equal to

the base of the cylinder in which it may be inscribed, and the solidity of this cylinder is equal to $\frac{2}{3}$ ds the solidity of the circumscribing sphere. Consequently the solidity of this cylinder

will be $= \frac{2}{3} a \times \frac{cm - dm - dn}{dm + dn}$; and the diameter of

its base equal to the diameter of the ball, will be $=$

$$\sqrt[3]{\frac{2}{3} a \times \frac{cm - dm - dn}{dm + dn}} \text{ or } \sqrt[3]{\frac{2}{3} a \times \frac{cm}{d \times m + n}} - 1.$$

It is evident that, *ceteris paribus*, the larger the bulb is, in proportion to the diameter of the cavity of the tube, or the narrower the latter is in proportion to the former, the greater will the motion of the surface of the fluid be in the tube. But it must be observed, that when the bulb is very large, the thermometer will not easily arrive at the precise temperature of any place, wherein it may be situated. Some persons, in order to give the bulb a greater surface, and of course to render it more capable of readily attaining a given temperature, have made it not globular, but cylindrical (which shape was adopted by Fahrenheit), or flat, or bell-like, &c.; but those shapes are improper, because they are liable to be altered by the varying gravity of the atmosphere, consequently those thermometers cannot be accurate. The bulb should be clean and colourless; since coloured surfaces are apt to be partially heated by a strong light. If you take two equal thermometers, and paint the bulb of one of them black, or of any dark colour, and expose them both to the sun; the mercury in that whose bulb is painted will rise several degrees higher than in the other: even a strong day-light, independently of the direct rays of the sun, will affect them differently. The ball of the thermometer should not be in contact with the substance of the scale, lest it should be influenced by the temperature of that substance.

When a proper tube and ball are procured, and their proportion ascertained, the next object which requires peculiar attention is that of filling the thermometer. For this purpose the tubes should be clean and dry, and the mercury very pure. (See MERCURY and BAROMETER.) The mercury may be introduced into the tube by means of a kind of reservoir fixed at the top of it, and proportioned in size to the bulk of the ball, or by rolling upon the tube a slip of fine paper, about two or three inches broad. In order to clear the tube of its air and moisture, it should be held over a gentle fire, so disposed, as that it may heat at once the whole extent of the tube, till its heat becomes too great for the operator's hand to bear, who therefore uses a glove or nippers for this purpose; care being taken that the ball is not heated at the same time. After the inclosed air is thus rarefied, and the particles that might obstruct the free motion of the mercury are made to float in vapours within the bore of the tube, the tube is to be held upright, and the ball suddenly heated, by which means the air contained in it will be dilated, and carry off the impurities of the tube, so that it will be rendered clean and free from air. When the ball is heated to a considerable degree, the mercury may be poured

into the reservoir fixed at the top of the tube, through a small corner of the paper. When the reservoir is almost full, the ball should be withdrawn from the fire, and the air will then be condensed, and the space left by it will be soon occupied by the mercury. By alternately heating and cooling the ball, it may thus be filled with mercury; but when it is nearly full, the mercury contained in it must be made to boil, by placing it over burning coals, in order to purge it of its air. However, as a small quantity of air will be left in the ball after this operation, it will be expedient to remove the mercury, which remains in the reservoir, immediately after the thermometer is withdrawn from the fire; and thus the whole column, un supplied with mercury from the reservoir, will descend into the ball by the condensation of that which is contained in it, and the tube being empty, the small bubble of air will escape. Let the tube be again heated successively through its whole length, commencing from the bottom, and preserving the heat of the ball, that the mercury may occupy it entirely, and no air be allowed to enter. During this operation, when the mercury of the thermometer begins to appear in the reservoir, let the mercury contained in a paper funnel be poured into it in such a quantity as will more than fill the thermometer, which is then to be removed from the fire. The mercury of the tube, and that discharged from the funnel, will unite, and pass together into the thermometer, and thus it will be wholly filled. In this state it may be left for any time at pleasure, without any apprehension of its imbibing either air or moisture. Nothing now remains but to get rid of the superfluous quicksilver, and to seal the tube. For this purpose the thermometer is held in the hand and heated, till a drop of mercury falls out of it, and is then left to recover the temperature of the air; by which means there will remain at the top of the tube a small empty space. Then with a blow-pipe and the flame of a candle, let the end of the tube be formed into a fine point, of such a length as will admit of its being properly sealed. When this preparatory process is completed, let the thermometer be gradually plunged into boiling water, so that the superfluous mercury may issue from it slowly; and when it ceases to be discharged, withdraw the thermometer from the boiling water; wipe it dry, and as soon as possible, put the ball of it over a small fire, covered with ashes, and previously prepared for the purpose. In this part of the operation, it is necessary to be quick, that the mercury may not have time to condense, and the air enter into the tube. In this state the thermometer may be left to heat, till it parts with more or fewer drops of the mercury, according to the proportion which the length of the tube bears to that of the scale applied to it. The thermometer is then sealed, by melting only the end of the point above mentioned, and at the same instant withdrawing it from the fire.

The method of filling the thermometer with a paper tube, or funnel, is as follows. Let the ball be heated, so that the mercury may rise to the top of the tube; whilst it approaches it, apply the tube of paper to the end of the tube, so that it may serve for a reservoir. The thermometer being placed near the fire, so that it may always preserve the same degree of dilatation, take some well purified mercury in a paper cornet, and communicate a little more heat to the ball. When the mercury rises, and forms a small drop at the end, pour the mercury of the cornet into the reservoir of paper, and withdraw the ball from the fire. Having removed the paper reservoir, place the ball again over the fire, and seal the point of the tube at the moment when the mercury rises to it, and withdraw the thermometer from the fire. This operation will be acquired by use.

THERMOMETER.

Thermometers that are desired for measuring great degrees of heat, require to be filled with particular precautions, which M. de Luc has minutely described.

When the thermometer is filled and sealed, nothing more is necessary than to mark the two fixed points, graduate the scale, and attach it to a proper frame. See de Luc's *Récherches*, &c. vol. i. p. 393, &c.

The frame may be made of any substance, or kind of wood, at pleasure: and the degrees may be marked on metal or wood, or paper, or ivory, &c.; but such substances should be preferred for the scales of thermometers as are not apt to be bent or shortened, or otherwise altered by the weather, especially if the instruments are not defended by a glass case, or by a box with a glass face. Thermometers for indicating the temperature of the atmosphere need not have scales that are much extended; if they go as high as 120° it is sufficient. The lower degrees may be carried down as low as may be necessary for the cold of any particular climate. The mercurial thermometer need not be graduated lower than 40° below 0, because at about that degree mercury ceases to be fluid. The spirit thermometer may be graduated lower, if necessary.

Thermometers used for observation, must be situated in the open air out of the house, and at the distance of a foot (at least) from the wall, and where the light of the sun may not fall directly upon them. For chemical purposes, the bulbs and part of the tubes of the thermometers should project some way below the scales, that they may be dipped in liquids, mixtures, &c. For other purposes, as for botanical observations, hot-houses, brewing manufactories, baths, &c. the thermometers must be made longer or shorter, or narrower; and particular directions may be given with regard to the scales and other appendages.

Great inconvenience has attended the use of various kinds of thermometers with different graduations. Kirwan proposed to lay all these aside, and to construct a general one, beginning at the congelation of mercury, and terminating at the boiling of water, and divided into 250°. Mr. Murray of Edinburgh has since suggested, that it would be convenient to form a scale whose extreme points should be the temperatures of freezing and boiling mercury, both which are now capable of being accurately ascertained, and to divide this scale into 1000°.

THERMOMETERS, Experiments with. We shall here insert a table of some observations made with the thermometers of Fahrenheit, Reaumur, sir Isaac Newton, and Dr. Hales.

Observations by Fahrenheit's Thermometer.

Deg.		
At 600	Mercury boils	}
546	Oil of vitriol boils	
242	Spirit of nitre boils	
240	Lixivium tartari boils	
213	Cow's milk boils	
212	Water boils.	
206	Fresh human urine boils.	
190	Brandy boils.	
174	Alcohol boils.	
176	— according to Muschenbroeck.	
156	Serum of blood and white of eggs hardens.	} According to Muschenbroeck, the barometer being at 29 Rhinland inches.
146	Killing heat for animals, in a few minutes.	
108	A hen hatching eggs, but seldom so hot.	
From 107	Heat of skin in ducks, geese, hens, pigeons, partridges and swallows.	
to 103		
At 106	Heat of skin in a common ague and fever.	

Deg.	
From 103	Heat of skin in dogs, cats, sheep, oxen, swine, and other quadrupeds.
to 100	
From 99	Heat of the human skin in health.
to 92	
At 97	Heat of a swarm of bees.
96	A perch died in three minutes, in water so heated.
80	
80	Heat of the air in the shade, in very hot weather.
74	Butter begins to melt.
64	Heat of the air in the shade, in warm weather.
48	
43	Temperate air, in England and Holland.
43	Oil of olive begins to stiffen and grow opaque.
32	Water just freezing, or snow and ice just thawing.
30	
30	Milk freezes.
28	Urine and common vinegar freezes.
25	Blood out of the body freezes.
20	Good Burgundy, strong claret, and Madeira freezes.
7	
7	One part of spirit of wine mixed with three parts water freezes.
5	Greatest cold in Pennsylvania in 1731-2, 40° lat.
4	
4	Greatest cold at Utrecht, in 1728-9.
0	A mixture of snow and salt, which is able to freeze oil of tartar <i>per deliquium</i> , but not brandy.
0	
- 39	Mercury freezes.

Martine's Essays, p. 284, &c.

We must here observe, that the heat of a hen hatching chickens is placed, by this table, at 108° of Fahrenheit's thermometer: but it appears from M. Reaumur's experiments, that eggs will hatch in a heat no greater than that of the human skin. See **HATCHING**.

See on the general subject of thermometers, Martine's Essays, Medical and Philosophical, printed at London in 1740, 8vo. Desaguliers's Exp. Phil. vol. ii. p. 289, &c. Muschenbroeck's Int. ad Phil. Nat. vol. ii. p. 625, &c. ed. 1762. De Luc's Recherches sur les Modifications de l'Atmosphere, tom. i. part ii. c. 2. Nollet's Leçons de Physique, tom. iv. p. 375, &c.

Thermometers for particular Uses. In 1757, the right hon. the earl of Cavendish presented to the Royal Society an account of a curious construction of thermometers, of two different forms; one contrived to shew the greatest de-

gree of heat, and the other the greatest cold, that may happen at any time in a person's absence. The first consists of a cylinder of glass joined to a tube, and differs from the common sort only in having the top of the stem drawn out into a capillary tube, which enters into a glass ball C (Plate XVI. Pneumatics, fig. 11.) joined on to the stem at the place where it begins to be contracted. The cylinder, and part of the tube, are filled with mercury, the top of which shews the common degrees of heat as usual. The upper part of the tube above the mercury is filled with spirit of wine, and some of the same liquor is left in the ball C, so as to fill it almost to the top of the capillary tube.

When the thermometer rises, the spirit of wine will be driven out of the tube, and will fall into the ball C. When the thermometer sinks again, as the spirit cannot be returned back from the ball, the top of the tube will remain empty, and the length of the empty part will be proportional to the fall of the thermometer. Consequently, by means of a proper scale, the top of the spirit of wine will shew how many degrees it has been higher than when observed, which being added to the present height, will give the greatest degree of heat it has been at. To fit this thermometer for a new observation, it is necessary to fill the upper part of the tube with spirits, by inclining the instrument till the spirits in the ball C cover the end of the capillary tube; for if the cylinder is then heated, by applying the hand to it, or by the flame of a lamp held at some distance, till the spirits rise to the top of the tube, and run over into the ball C, and is then suffered to cool in the same position, the tube will remain full of spirits, and the thermometer will be fitted for a new experiment.

The scale of degrees at top, which shews the descent of the thermometer from the highest point it has arrived at, ought not, in strictness, to be the same at all times of the year; for these degrees exceed the common degrees of heat pointed out by the top of the mercury, as much as the column of spirit of wine expands, and therefore are greatest when that column is so; *i. e.* when the greatest heat to which the instrument has been exposed is least. A difference of 30 degrees of Fahrenheit's scale, in the greatest rise of the thermometer, would require the scale to be altered one sixtieth part; and the error arising from making use of the same scale, will be about one-sixth of a degree, if the thermometer is observed when it has fallen ten degrees.

In the thermometer here described, the bore of the tube is about 0.027 inches; and one inch of it contains two grains of mercury, and answers to about ten degrees, the cylinder containing about 2280 grains. When the scale of degrees is large, the cylinder must be of considerable size. The quicksilver in the ball C serves to supply the tube, in case any of it should be driven into the ball by the thermometer's being exposed to too great a heat.

If the weight of the mercury be thought inconvenient, it may be avoided by the construction in fig. 12. where the bottom of the tube is bent so as to point upwards, and is joined to a ball A, which communicates with a cylinder placed above it. It is in all other respects the same as the former instrument. It is filled with spirits of wine and mercury; the quantity of the latter being sufficient to fill the whole tube and the ball A.

The thermometer for shewing the greatest degree of cold that happens in any place during the time the instrument is left in it, is represented in fig. 13. The tube is bent into the shape of a siphon, of unequal legs, standing parallel to one another; the top of the shorter leg is bent to a right angle, and opens into a ball A, which, by means of a short bent tube on the opposite side, communicates with a cylinder

THERMOMETER.

der standing parallel to the legs of the siphon, and pointing downwards. This cylinder contains the greatest part of the fluid, and is added only to make the thermometer more sensible than it would be, if the ball A was made of a sufficient size to contain the proper quantity of fluid. This instrument is filled with spirit of wine, with the addition of as much mercury as is sufficient to fill both legs of the siphon, and about a fourth or fifth part of the ball A. The common degrees of heat are shewn by the top of the mercury in the longest leg, or by the top of the spirit, in case any of it is left above the mercury. When the mercury in the longest leg sinks by cold, that in the shorter leg will rise, and will run over into the ball A; from whence it cannot return back when the thermometer rises again, as the surface of the mercury in the ball is below the orifice of the tube *n*. Therefore the upper part of the shorter leg will be filled with a column of spirits of a length proportional to the increase of heat; the bottom of which, by means of a proper scale, will shew how much the thermometer has been lower than it is; which being subtracted from the present height, will give the lowest point that it has been at. In order to prevent the mercury from falling into the ball A in large drops, which would affect the accuracy of the instrument, the top of the shorter leg, close to the ball, is contracted, by being held in the flame of a lamp, and the passage farther straightened by a solid thread of glass placed within the tube, and extending from the bottom of the shorter leg to the part near the ball A, where it is most contracted. By this means, as soon as any small portion of mercury is got beyond the thread of glass, it breaks off, and falls into the ball in very small drops.

In order to fill the shorter leg with mercury, for a new experiment, it must be inclined till the mercury in the ball covers the orifice of the tube *n*. The cylinder being then heated, the mercury will be forced into the shorter leg, and will run down the thread of glass in drops, which will soon unite. Thus such a quantity of mercury must be got into the shorter leg, as, upon the cooling of the instrument, will be sufficient to drive all the spirit of wine into the ball, with a less degree of cold than what the thermometer is likely to be exposed to. The ball A must always have some mercury in it, but never enough to fill it up to the orifice of the tube *n*. It will be best to leave a little of the spirit above the mercury in the longest leg; in which case the top of the spirit will shew the common degrees of heat. The scale of degrees on the shorter leg will, in different seasons, be liable to an error similar to that which was explained in the first mentioned thermometer; but it will be less considerable, as the space between the two scales is filled with mercury, whose expansion is about six times less than that of the spirit of wine. In the thermometer now described, the bore of the tube is about 0.054 inches; and one inch of it contains eight grains of mercury, and answers to seven degrees of Fahrenheit's scale. The drops of mercury which fall into the ball A, answer to about one-eighth of a degree.

Instruments of this kind, with some alteration in their construction, would serve for finding the temperature of the sea at great depths, and also for finding that of the air at considerable heights. Lord Charles Cavendish has shewn how to adapt them for such purposes. See *Phil. Trans.* vol. I. art. 38. p. 300, &c.

Since the publication of Mr. Canton's discovery of the compressibility (see COMPRESSION) of spirits of wine and other fluids, there are two corrections necessary to be made in the result given by lord Charles Cavendish's thermometer. For in estimating, *c. g.* the temperature of the sea at any depth, the thermometer will appear to have been colder than

it really was: and besides, the expansion of spirits of wine by any given number of degrees of Fahrenheit's thermometer is greater in the higher degrees than in the lower. For the method of making these two corrections by Mr. Cavendish, see Phipps's Voyage to the North Pole, p. 145.

Instruments of this kind, for determining the degree of heat or cold in the absence of the observer, have been invented and described by others. Van Swinden (*Diff. sur la Comparison du Therm.* p. 253—255.) describes one, which, he says, was the first of the kind made on a plan communicated by M. Bernouilli to M. Leibnitz. M. Kraft, he also tells us, made one nearly like it. Mr. Six, in 1782, proposed another construction of a thermometer of the same kind, which has been well received.

This is properly a spirit thermometer, though mercury is employed in it for the purpose of supporting a certain index: *ab* (*fig.* 14.) is a tube of thin glass, about sixteen inches long, and $\frac{1}{16}$ ths of an inch in diameter; *cdefgh* is a smaller tube, with the inner diameter about $\frac{1}{8}$ th, joined to a larger at the upper end *b*, and bent down first on the left side, and then, after descending two inches below *ab*, upwards again on the right, in the several directions *cde*, *fgh*, parallel to, and one inch distant from it. At the end of the same tube at *b*, the inner diameter is enlarged to half an inch from *b* to *i*, which is two inches in length. This glass is filled with highly rectified spirit of wine to within half an inch of the end *i*, excepting that part of the small tube from *d* to *g*, which is filled with mercury. From a view of the instrument it will be readily conceived, that when the spirit in the large tube is expanded by heat, the mercury in the small tube on the left side will be pressed down, and cause that on the right side to rise: on the contrary, when the spirit is condensed by cold, the reverse will happen. Fahrenheit's scale, which begins with 0 at the top of the left side, has the degrees numbered downwards, while that at the right side, beginning with 0 at the bottom, ascends. The divisions are ascertained by placing the thermometer with a good standard mercurial one in water, gradually heating or cooling, and marking the divisions of the new scale at every five degrees. The divisions below the freezing point are taken by means of a mixture of sea-salt and ice, as described by Nollet, De Luc, and others. In order to shew how high the mercury has risen in the observer's absence, there is placed within the small tube of the thermometer, above the surface of the mercury on either side, immersed in the spirit of wine, a small index, so fitted as to pass up and down as occasion may require. One of these indices is represented in *fig.* 15; *a* is a small glass tube, three-quarters of an inch long, hermetically sealed at each end, inclosing a piece of steel wire nearly of the same length; at each end *c, d*, is fixed a short piece of a tube of black glass, of such a diameter as to pass freely up and down within the small tube of the thermometer. The lower end, floating on the surface of the mercury, is carried up with it when it rises, while the piece at the upper end, being of the same diameter, keeps the body of the index parallel to the sides of the thermometrical tube. From the upper end of the body of the index at *e* is drawn a spring of glass to the fineness of a hair, about five-fourths of an inch in length, which being set a little oblique, presses lightly against the surface of the tube, and prevents the index from following the mercury when it descends, or being moved by the spirit passing up and down, or by any sudden motion given to the instrument; but at the same time the pressure is so adjusted as to permit this index to be readily carried up by the surface of the rising mercury, and downwards, whenever the instrument is rectified for observation. This index, by not returning

THERMOMETER.

turning with the mercury when it descends, shews distinctly and accurately how high the mercury has risen, and consequently what degree of cold or heat has happened. To prevent the spirit from evaporating, the tube at the end is closely sealed. The daily rectification of this instrument is performed, by applying a small magnet to that part of the tube against which the index rests; by the action of which the included piece of steel wire, and consequently the index, is easily brought down to the surface of the mercury. When this has been done, the instrument is rectified for the next day's observation, without heating, cooling, separating; or at all disturbing the mercury, or moving the instrument. With a thermometer of this sort, Mr. Six observed the greatest heat and cold that happened every day and night throughout the year 1781. But for the more particular description of this instrument, the illustration of it by figures, and an account of its advantages, the limits of this work require our referring to Phil. Trans. vol. lxxii. part i. p. 72, &c.

A similar effect to that produced by Six's thermometer is obtained in Rutherford's arrangement of a pair of thermometers, one with mercury, the other with spirit of wine, placed in a horizontal position; one index being without the surface of the mercury, the other within that of the spirit: the thermometers being in contrary directions, both indices may be brought back to their places, by merely raising the end of the instrument. (See fig. 16.) Self-registering thermometers have also sometimes been constructed for keeping a still more accurate account of all the variations of temperature that have occurred, by describing a line on a revolving barrel, which shews the height for every instant during the whole time of their operation.

M. de Luc has described the best method of constructing a thermometer, fit for determining the temperature of the air, in the mensuration of heights by the barometer. He has also shewn how to divide the scale of a thermometer, so as to adapt it for astronomical purposes in the observation of refraction. See *Récherches, &c.* tom. ii. p. 35, &c. p. 265, &c.

Mr. Cavallo, in 1781, proposed the construction of a thermometrical barometer, which, by means of boiling water, might indicate the various gravity of the atmosphere, or the height of the barometer. This thermometer, he says, with its apparatus, might be packed up into a small portable box, and serve for determining the heights of mountains, &c. with greater facility than with the common portable barometer. The instrument, in its present state, consists of a cylindrical tin vessel, about two inches in diameter, and five inches high, in which vessel the water is contained, which may be made to boil by the flame of a large wax-candle. The thermometer is fastened to the tin vessel in such a manner, as that its bulb may be about one inch above the bottom. The scale of this thermometer, which is of brass, exhibits on one side of the glass tube a few degrees of Fahrenheit's scale, *viz.* from 200° to 216° . On the other side of the tube are marked the various barometrical heights, at which the boiling water shews those particular degrees of heat which are set down in sir G. Shuckburgh's table. With this instrument the barometrical height is shewn within one-tenth of an inch. The degrees of this thermometer are somewhat longer than one-ninth of an inch, and therefore may be divided into many parts, especially by a Nonius. But the greatest imperfection of the instrument arises from the smallness of the tin vessel, which does not admit a sufficient quantity of water; but when the quantity of water is sufficiently large, *e. g.* 10 or 12 ounces, and is kept boiling

in a proper vessel, its degree of heat under the same pressure of the atmosphere is very settled; whereas when a thermometer is kept in a small quantity of boiling water, the quicksilver in its stem does not stand very steady, sometimes rising or falling even half a degree. Mr. Cavallo proposes a farther improvement of this instrument in the Phil. Trans. vol. lxxi. part ii. p. 524.

The ingenious Mr. Wedgwood, so well known for his various improvements in the different sorts of pottery-ware, has contrived to make a thermometer for measuring the higher degrees of heat, by means of a distinguishing property of argillaceous bodies, *viz.* the diminution of their bulk by fire. This diminution commences in a low red heat, and proceeds regularly, as the heat increases, till the clay becomes vitrified. The total contraction of some good clays which he has examined in the strongest of his own fires, is considerably more than one-fourth part in every dimension. If, therefore, we can procure at all times a clay sufficiently apyrous or unvitrescible, and always of the same quality in regard to contraction by heat; and if we can find means of measuring this contraction with ease and accuracy, we shall be furnished with a measure of fire sufficient for every purpose of experiment or business. Some of the purest Cornish porcelain clays (which, by the analysis of Mr. Wedgwood, appear to contain no calcareous earth nor gypseous matter, but to consist of pure argillaceous or alum earth, and another indissoluble earth, which he apprehends to be of the siliceous kind, in the proportion of three parts of the former to two parts of the latter) seem the best adapted, both for supporting the intensity, and measuring the degrees of fire. This material is prepared for use by washing it over, and whilst in a diluted state passing it through a fine lawn: it is then dried and put up in boxes. The dry clay is to be softened for use with about two-fifths its weight of water; and formed into small pieces, in little moulds of metal, $\frac{5}{8}$ ths of an inch broad, with the sides exactly parallel; about $\frac{3}{8}$ ths of an inch deep, and an inch long. The moulds are to be oiled and warmed. These pieces, when perfectly dry, are put into another iron mould or gage, consisting only of a bottom, with two sides, $\frac{5}{8}$ ths of an inch deep, to the dimensions of which sides the breadth of the pieces is to be pared down. For measuring the diminution which they are to suffer from the action of fire, another gage is made of two pieces of brass, twenty-four inches long, with the sides exactly straight, divided into inches and tenths, fixed five-tenths of an inch asunder at one end, and three-tenths at the other, upon a brass plate; so that one of the thermometric pieces, when pared down in the iron gage, will just fit to the wider end. If this piece be supposed to have diminished in the fire one-fifth of its bulk, it will then pass on to half the length of the gage; if diminished two-fifths, it will go on to the narrowest end: and in any intermediate degree of contraction, if the piece be slid along till it rests against the converging sides, the degree at which it stops will be the measure of its contraction, and consequently of the degree of heat it has undergone. The thermometric pieces may be formed much more expeditiously than in the single mould by means of an instrument, consisting of a cylindrical iron vessel, with holes in the bottom, of the form and dimensions required.—The soft clay, put in the vessel, is forced by a press down through these apertures, in long rods, which may be cut while moist, or broken when dry, into pieces of convenient lengths. After which, recourse should be had to the paring gage for ascertaining and adjusting their breadth when perfectly dry.

Each division of the scale, though so large as a tenth of

THERMOMETER.

an inch, answers to $\frac{1}{10}$ th part of the breadth of the little piece of clay. When one gage is accurately adjusted to the proportional measures above stated, two pieces of brads should be made, one fitting exactly into one end, and the other into the other; which will serve as standards for the ready adjustment of other gages to the dimensions of the original, and thus we may be assured, that thermometers on this principle, though made by different persons, and in different countries, will all be equally affected by equal degrees of heat, and all speak the same language. The scale commences at a red heat fully visible in day light; and the greatest heat which Mr. Wedgwood has hitherto obtained in his experiments, is 160° . Swedish copper has been found to melt at 27° , silver at 28° , and gold at 32° , of this thermometer. Brads is in fusion at 21° : the welding heat of iron is from 90° to 95° , and the greatest heat that could be produced in a common smith's forge, 125° . Cast iron melted at 130° ; and the heat by which iron is run down among the fuel for casting is 150° . A Hessian crucible melted into a slag-like substance at about 150° . The fusing heat of glass furnaces, or that by which the perfect vitrifications of the materials is produced, was at one of them 114° for flint-glass, and 124° for plate-glass. Delft-ware is fired by a heat of 40° or 41° ; Queen's-ware by 86° ; and stone-ware by 102° , which degree of heat changes it to a true porcelain texture. The thermometer pieces begin to acquire a porcelain texture at about 110° . A piece of an Etruscan vase melted completely at 33° ; pieces of other vase and Roman ware about 36° ; Worcester china vitrified at 94° ; Mr. Sprimont's Chelsea china at 105° ; the Derby at 112° ; the Bow at 121° ; but Bristol china shewed no appearance of vitrification at 135° . The common sort of Chinese porcelain does not perfectly vitrify by any fire which Mr. Wedgwood could produce: but began to soften about 120° , and at 156° became so soft as to sink down and apply itself close upon an irregular surface underneath. The true stone Nankeen does not soften in the least, by this strong heat; nor even acquire a porcelain texture. The Dresden porcelain is more refractory than the common Chinese, but not equally so with the stone Nankeen. The cream-coloured or Queen's-ware bears the same heat as the Dresden. Mr. Pott says, that to melt a mixture of chalk and clay in certain proportions, which appear from his tables to be equal parts, is "among the master-pieces of art." This mixture melts into a perfect glass at 123° of this thermometer. For other curious particulars, see Phil. Trans. vol. lxxii. part ii. p. 305, &c.

This thermometer, says Dr. Young, (Lect. on Nat. Philos. vol. i. 648.) may be extremely useful for identifying the degree of heat which is required for a particular purpose; but for the comparison of temperatures by an extension of the numerical scale, we have not sufficient evidence of its accuracy to allow us to depend on its indications; and it is scarcely credible, that the operation of furnaces of any kind, can produce a heat of so many thousand degrees of a natural scale, as Mr. Wedgwood's experiments have led him to suppose; nor is the supposition consistent with the observations of other philosophers.

THERMOMETER, Differential, a curious sort of thermometer invented by professor Leslie, which expresses not the absolute degree of heat, but the difference, when any exists, between the temperatures of the two spots where its two bulbs are placed. The method of constructing it is as follows. (See Plate XVI. *Pneumatics*, fig. 17.) Select two thermometer tubes with bores rather wider than usual, and one a little wider than the other. Let the balls be blown

as equal as the eye can judge, and from .4 to .7 of an inch in diameter, and let the open end of the tube also be widened in a slight degree. The tubes must be of unequal length, the longest being nearly twice the length of the other. Then introduce into the longer tube a little sulphuric acid tinged with carmine, sufficient to fill about an inch of its cavity; join the two tubes together by the blow-pipe, and when joined, bend them in the form of the letter U, with the bulbs about three or four inches asunder, making one flexure just below the juncture of the two tubes, where the small cavity (which is represented in the plate) facilitates the adjustment of the instrument, which by a little dexterity is performed by forcing a few globules of air by the heat of the hand from one bulb to the other. Attach a graduated scale to the shorter tube, making the zero about the middle of it, and adjust to it the quantity of air in each bulb, so that when the bulbs are at the same temperature, the upper surface of the coloured liquor may just correspond with the zero. Sulphuric acid is chosen as the liquor interposed between the bulb, on account of its bearing any heat or cold that would be used without being evaporated or congealed.

In this instrument the air inclosed in the bulbs is the substance, which, by its expansion or contraction, causes the motion of the coloured liquor up or down the scale, and as gases are much more expansible than liquids, the instrument is sooner affected by minute changes of heat. But as the two bulbs are of equal size, and both filled with air, and separated from each other by the intervening liquor, it is obvious that when the temperature is the same in each bulb, be it high or low, the pressure on each side of the liquor is also equal, and it must remain stationary: so that it can only move when one bulb is warmer than the other. Hence the particular and sole use of this instrument as a differential thermometer. The lower part of the instrument (or the space included between the two bends) is cemented to an upright stem, by which it is supported.

This instrument has been employed by the inventor in a variety of curious experiments on caloric, or the matter of heat. The peculiar advantage which this instrument possesses is, that, besides its extreme sensibility, in using it the common temperature of the surrounding air may, in general, be disregarded; this being always the zero of the scale, whatever be the actual variation of heat in the surrounding atmosphere; and hence a much greater degree of simplicity is introduced into the delicate researches on this subject. For the reflection of heat mirrors were employed, generally of block-tin, highly polished, and hammered to fit a wooden gage, the segment of a parabolic curve, by which much of the dispersion produced by a simple concave form was avoided; so that when exposed to the direct rays of the sun, they collected them into a pretty distinct focus, of about half an inch in diameter. The substance employed to generate the radiant heat was a hollow cubic tin canister, placed directly in front of the mirror of its focal point, and when used, filled with boiling water, and fitted with a common thermometer, passing through a hole in the cover, and immersed in the water. The cubical form of the canister allowed of four sides, of perfectly equal dimensions, each of which, when turned to the mirror, afforded a heated surface for the transmission of radiant caloric, and they were occasionally coated with various substances to ascertain the effect of colour, polish, and the like, in retarding or promoting the radiation of the heat within. With this apparatus, and his differential thermometer, Mr. Leslie performed a variety of interesting experiments,

THERMOPOLIUM, formed of *θερμός*, hot, and *πόλις*, I fell, a name for a sort of public houses among the ancients, in which hot liquors were sold, in the manner of our coffee-houses.

THERMOPSIS, in Botany, from *θερμός*, a Lupine, and *opsis*, appearance or aspect, indicating a general resemblance to that genus of plants.—Brown in Ait. Hort. Kew. v. 3. 3.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Ess. Ch. Calyx oblong, five-cleft half way down, two-lipped; convex behind; tapering at the base. Corolla papilionaceous; petals nearly of equal length; standard reflexed at the sides, keel obtuse. Stamens permanent. Legume compressed, linear, with many seeds. *Br.*

1. *Th. lanceolata*. Sharp-leaved Thermopsis. Ait. n. 1. (*Podalyria lupinoides*; Willd. Sp. Pl. v. 2. 504. *Sophora lupinoides*; Linn. Sp. Pl. 534. "Pallas Astrag. 119. t. 89.")—Leaflets oblong-lanceolate. Stipulas lanceolate, twice as long as the footstalks. Flowers whorled.—Native of Siberia; from whence the late duke of Northumberland is said to have received it in 1776. This is a hardy perennial herbaceous plant, flowering in June and July. The stems are spreading or decumbent, about a foot long, branched in an alternate manner, round, hairy, leafy. Leaves ternate, light green, hairy, on short stalks; their leaflets about an

inch long. Stipulas half as large, or more. Flowers stalked, about three in each whorl, yellow, much resembling those of a Lupine. Calyx hairy.

By Mr. Brown's specific character, we presume there are more species of this genus, though not in our gardens, of which he will one day give an account. For the soundness of the generic distinctions, we rely on him. The compressed legume seems the most important difference between *Thermopsis* and the *Baptista* of Ventenat and Brown; see Ait. Hort. Kew. v. 3. 5; also our articles SOPHORA and PODALYRIA.

THERMOPYLÆ, in *Ancient Geography*, a strait or pass, rendered famous by the valour of Leonidas and his companions, who defended it against the army of Xerxes in the year 480 B.C; and which, long after that celebrated event, was defended against the Gauls. This pass is the only road by which an army can penetrate from Thessaly into Locris, Phocis, Bœotic, Attica, and the adjacent countries. The following succinct description is given of this strait by the abbé Barthelemy, in his "Anacharsis." On quitting Phocis to go into Thessaly, having passed the little country of the Locrians, we arrive, says the abbé, at the town of Alpenus, situated by the sea. As it stands at the entrance of the strait, it has been fortified. The road at first is only wide enough for the passage of a waggon; but

it afterwards enlarges itself between morasses formed by the waters of the sea and almost inaccessible rocks, which terminate the chain of mountains known by the name of Oeta. After leaving Alpenus, a stone is discovered on the left, consecrated to Hercules Melanpygus, and a path presents itself that leads to the summit of the mountain. Farther on, the traveller crosses a current of hot water, which gives this place its name of Thermopylæ. Next to this stream is the town of Anthela; and in the plain which furrounds it are a small eminence and a temple of Ceres, in which the Amphictyons annually held one of their assemblies. On coming out of the plain there is a road, or rather causeway, only about seven or eight feet wide. Here the Phocians had formerly built a wall, to protect their country from the inroads of the Thessalians. After passing the Phœnix, which at last falls into the Afopus, a river that rises in an adjacent valley, we come to the last defile, half a plethrum (15 or 16 yards) in breadth. The road then widens as far as Trachinia, which takes its name from the city of Trachis, that was inhabited by the Mahians. This country presents to the view of the traveller extensive plains watered by the Sperchius and other rivers. To the E. of Trachis stood the city of Heraclea, which did not exist in the time of Xerxes. The whole strait, from the defile before we arrive at Alpenus to that which is beyond the Phœnix, may be about 48 stadia (about 2 leagues) in length. Its breadth varies almost at every step; but through its whole extent it is shut in on one side by steep mountains, and on the other by the sea, or impenetrable morasses. The road is often destroyed by the torrents, or by stagnant waters. Leonidas posted his little army near Anthela, rebuilt the wall of the Phocians, and dispatched a few advanced troops to defend the approaches. But it was not sufficient to guard the passage at the foot of the mountain; on the mountain itself there was a path, which, beginning at the plain of Trachis, terminated, after various windings, near the town of Alpenus. Leonidas entrusted the defence of this path to the thousand Phocians he had with him, and who took post on the heights of mount Oeta. As soon as these arrangements were completed, the army of Xerxes was discovered, spreading itself over Trachinia, and covering the plain with its innumerable tents. The Greeks deliberated on the measures proper to be adopted; most of the generals were for retiring to the isthmus; but Leonidas rejected this counsel. A Persian horseman was deputed to reconnoitre the advanced post of the Greeks, which was composed of Spartans; and as the rest of the army was concealed from him by the wall, he only gave an account to Xerxes of the 300 men he had seen at the entrance of the defile. After various messages from Xerxes to Leonidas, and the firm and calm replies of the latter, the Persian king was enraged, and gave orders for an attack. The Medes rushed on with fury, and one rank fell after another, while the Greeks, pressing close against each other, and covered with large bucklers, presented an impenetrable front of long pikes, and a phalanx which fresh troops successively in vain attempted to break. At length the Medes were seized with a panic, and fled; but they were speedily relieved by the chosen body of the 10,000 immortals, commanded by Hydarnes. The action now became more bloody; but the Greeks had the advantage of situation, and superiority of arms. The Persians lost many men; and Xerxes, witnessing their flight, leaped, as it is said, more than once from his chariot, and trembled for their fate. Next day the attack was renewed, but with so little success, that Xerxes despaired of forcing the passage. At length Epialtes, an inhabitant of those districts, discovered to him the fatal path by which he might turn the Grecians; and served as a guide

to Hydarnes and his corps of immortals, under whose conduct they arrived near the spot where Leonidas had posted a detachment of his army; and prepared to attack it. When this dreadful news reached the Greeks, their leaders assembled. Some were for retreating, and others for remaining; but Leonidas declared for himself and his companions, that they were not permitted to quit a post which Sparta had confided to their care. In the middle of the night, the Greeks, with Leonidas at their head, issued out of the defile, advanced through the plain, overthrew the advanced posts, and penetrated to the tent of Xerxes, who had already taken flight. They spread over the camp, and glutted themselves with carnage. The Persians were terrified and confused, and many of them perished by the hands of one another. At length, with the dawn of day they discovered the inconsiderable number of their victors, and rallying, attacked the Greeks on all sides. Leonidas fell beneath a shower of darts; and a contest for the honour of carrying off his body, occasioned a terrible conflict between his companions and the most expert and hardy warriors of the Persian army. The Greeks, however, prevailed, and carried off their general; and having regained the defile, posted themselves on an eminence, and for some time continued to defend themselves. When Xerxes offered to Leonidas the empire of Greece, if he submitted to his power, he replied, "I rather choose to die free than to enslave my country." When the king commanded him to surrender his arms, he wrote the laconic answer, "come and take them." "The Persians are near us," said one of his soldiers to Leonidas: "rather say," he coolly replied, "that we are near the Persians." See LEONIDAS.

It has been a subject of dispute what was the number of Grecian troops under the command of Leonidas at Thermopylæ. Herodotus states them at 5100, Pausanias at 11,200, and Diodorus at 7400. The abbé Barthelemy attempts to reconcile these different statements, and concludes, upon the whole, that Leonidas had with him about 7000 men. If we may credit Diodorus, he had no more than 500 soldiers when he determined to attack the Persian camp.

On the eminence to which the companions of Leonidas retired after the death of their commander, there were several monuments erected by order of the Amphictyonic council, in honour of the 300 Spartans, and the other Grecian troops engaged in the combat. On one of these cippi is inscribed, "Here four thousand Greeks of Peloponnesus fought against three millions of Persians."

THERMOSCOPE, an instrument shewing the changes happening in the air with respect to heat and cold.

The word thermoscope is generally used indifferently with that of thermometer. There is some difference, however, in the literal import of the two; the first signifying an instrument that shews or exhibits the changes of heat, &c. to the eye; formed from θερμη, heat, and σκοπεω, video, I see; and the latter an instrument that measures those changes, from θερμη, heat, and μετρον, to measure, on which foundation the thermometer should be a more accurate thermoscope, &c. This difference the excellent Wölfius taking hold of, describes all the thermometers in use as thermoscopes; shewing that none of them properly measure the changes of heat, &c. none of them do more than indicate the same. Though their different heights yesterday and to-day shew a difference of heat; yet, since they do not discover the ratio of yesterday's heat to to-day's, they are not strictly thermometers.

THERONDELS, in *Geography*, a town of France, in the department of the Avairon; 3 miles N.E. of Mur.

THEROUANNE, a town of France, in the department of the Straits of Calais, on the Lys. It was anciently the

the capital of the Morini, and afterwards an episcopal see, with several churches and convents; but being taken in the year 1553 by the emperor Charles V., he demolished it. The district belonging to it, however, was ceded by Spain to France, at the treaties of the years 1559 and 1659; 6 miles S. of St. Omer.

THERSA, or **THAPSA**, in *Ancient Geography*, a royal town of Judea, in the half-tribe of Manasseh, on this side of Jordan. Therfa was the seat, capital, and burying-place of the first kings of Israel.

THERSA, or *Thirza*, a town of Palestine, in the tribe of Ephraim.

THERSARA, a town of Asia, in the interior of Assyria. Ptolemy.

THERSITÆ, a people of Spain, in Iberia; they were of the number of those whom Annibal caused to pass into Africa.

THERUINGI, a people who inhabited a part of Dacia, on the other side of the Danube.

THESBON, a town of Palestine, on the other side of Jordan, in the tribe of Gad.

THESEA, or **THESEA**, **Θησεα**, in *Antiquity*, feasts celebrated by the Athenians in honour of Theseus.

In spite of the important services that hero had done his country, in delivering it from a shameful tribute of so many youths, of either sex, sent yearly to be devoured by the Minotaur in Crete (as the fable has it), or sent as slaves to Minos, king of Crete, as the histories have it, from which he freed them, by overturning Taurus, Minos's general; he was banished for some time, and retired to Scyros, under the protection of Lycomedes, king of that island, where he finally lost his life either by accident, or in consequence of the jealousy of the king.

The gods, it is said, revenged this treatment Theseus received from the Athenians, by afflicting them with a famine, which the oracle assured them should not cease till they had avenged his death. Upon this they slew Lycomedes, brought Theseus's bones to Athens, placed them in a temple erected to him, and appointed Thesea to be held every eighth day of each month, in which largesses were distributed to the people, and the day was spent, by the rich, in feasting and rejoicing, and with peculiar solemnity on the eighth day of the month Pyanepsion.

Plutarch, however, gives a different account of the origin of this feast; he says that the Athenians, imagining they saw Theseus at the battle of Marathon under the form of a tutelary deity, consulted the oracle on this prodigy: and being ordered to collect his bones in the island of Scyros, removed them with great pomp to Athens; and deposited them under a magnificent monument erected in the middle of the city, which became afterwards an asylum for slaves, in commemoration of the success afforded by this prince to the unfortunate during his life. They also erected a temple where they offered sacrifices, &c. At Rome, Theseus was held in very different estimation, for Virgil (*Æn.* lib. vi.) places him in Tartarus, among those who were tormented for their crimes.

THESEUS, in *Biography*, a hero celebrated in the fabulous ages of Greece, and referred by chronologers to the thirteenth century B.C. was the illegitimate son of Ægeus, king of Athens, by Æthra, daughter of Pittheus, king of Trœzern; and as he advanced towards maturity discovered a vigorous spirit in an athletic frame. In his journey to Athens by land he met with many adventures and conflicts, and on his arrival found the city agitated by dissensions. The sons of Pallas, the brother of Ægeus, suspecting that the aged and childless sovereign would adopt this newly arrived stranger for his heir, fomented his jealousies, so that

Ægeus prepared poison for dispatching him; but before his plan could be accomplished, he discovered by certain tokens that he was his son. The consequence of this discovery was a revolt of the Pallantides, which Theseus suppressed.

For an account of the further exploits of Theseus for the relief of the Athenians, we refer to our article *History of Athens*. Theseus having, in the manner there related, established a constitution for the Athenians, yielded to the impulse of ambition; and quitting his throne, and sometimes in the company of Hercules and sometimes of Pirithous, son of Ixion, king of Thessaly, whose friendship he had secured, undertook a variety of enterprizes, the account of which is so intermixed with the fabulous, that it is impossible satisfactorily to develop it. He is said, however, to have conquered certain Amazons on the banks of the Thermodon, in Asia, taking a queen from among them for his wife; to have assisted Pirithous in overcoming the Centaurs in Thessaly; and to have stolen away from Sparta the celebrated Helen; and afterwards to have joined the same friend in a similar attempt upon Proserpina, the daughter of Aidoneus, king of the Molossians, in which Pirithous lost his life, and Theseus underwent an imprisonment, from which Hercules procured his escape. Upon his return from this romantic expedition, he found his kingdom and family in confusion. Castor and Pollux, the brothers of Helen, ravaged Attica by way of revenge for the insult offered to their sister. His queen Phædra, falling in love with Hippolytus, his son by the Amazon, and being rejected, calumniated him to his father, and occasioned his death, as his tragedy has recorded. From a variety of circumstances that occurred, Theseus finding that he had lost the attachment of the Athenians, abandoned the city, and intended to repair to Demetrius, son of Minos, now reigning in Crete. In his passage thither he was driven by a storm to the isle of Scyros, where he was kindly received by the king, Lycomedes; but soon afterwards he lost his life by a fall from a rock. (See **THESEA**.) The resentment of the Athenians afterwards subsided, and they regarded him only as a hero and benefactor; and Cimon, son of Miltiades, having conveyed his bones, as they were supposed to be, to Athens, in consequence of the injunctions of an oracle, a magnificent temple was erected over them, which was made an asylum for the unfortunate. Its remains still subsist as one of the noblest relics of ancient art in that famous capital. Plut. in Vit. Thesei. Anc. Univ. Hist. Travels of Anacharsis, vol. i.

THESIN.—*Per Arsin and Thesin*. See **PER ARSIN**.

THESIS, **θεσις**, *positio*, formed from **τιθημι**, *I put or lay down*, in the *Schools*, a general proposition, which a person advances, and offers to maintain.

In the college it is frequent to have placards, containing a number of these theses in theology, in medicine, in philosophy, in law, &c. The maintaining a thesis, is a great part of the exercise a student is to undergo for a degree.

THESIS, in *Logic*, &c.—Every proposition may be divided into thesis and hypothesis; thesis contains the thing affirmed or denied, and hypothesis the conditions of the affirmation or negation.

Thus, in Euclid, if a triangle and parallelogram have equal bases and altitudes (is the hypothesis), the first is half of the second (the thesis).

Arsis and Thesis. See **ARSIS**.

THESIS, **θεσις**, *depositio* or *remissio*, the beating down the hand or foot at the beginning of a bar in music. See **ARSIS**, *tollo*, which is the lifting up the hand or foot in the middle or latter part of a bar.

THESIUM, in *Botany*, an ancient name, adopted from the Greeks, enumerated by Linnæus, Phil. Bot. 174, among

those whose derivation is extremely difficult, and, after all, doubtful. Pliny has the *Thesium* in two places; book 21. chap. 17, and book 22. chap. 22. In the former, it is mentioned amongst bulbous plants, as having a harsh taste: in the latter, it stands next to *Pteris*, as very bitter, and purgative. This last account is copied from Theophrastus, who, in his book 7. chap. 11, speaks of *ἄνισον* in the same terms, along with a number of plants of the Sow-thistle and Dandelion tribe, or *Cichoraceæ*. To these indeed some of the *Arum* family are subjoined, and *Thesium* is placed at the end. All we can hence gather is, that the plant in question may possibly be some plant of the *Syngenesia Polygamia-aqualis*, of the section *semiflosculosa*, whose root is tuberous. Of this description there are several natives of Greece; see SCORZONERA, n. 12 and 13. Ambrosini derives the word from *θεσ*, a servant, or rather a poor tradesman, because, as he thinks, of its being serviceable in many respects, both for food and medicine. Possibly Linnæus, who frequently consulted this author, may hence have been led to apply the name of *Thesium* to the present genus, totally different indeed from all that is recorded of the Greek *ἄνισον*, but remarkable for its mean habit and hardy texture.—Linn. Gen. 114. Schreb. 160. Willd. Sp. Pl. v. 1. 1211. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 269. Prodr. Fl. Græc. Sibth. v. 1. 164. Ait. Hort. Kew. v. 2. 63. Pursh 177. Brown Prodr. Nov. Holl. v. 1. 352. Juss. 75. Lamarck Illustr. t. 142. Gærtn. t. 86.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Veprecule*, Linn. *Elzagni*, Juss. *Santalaceæ*, Brown.

Gen. Ch. *Cal.* Perianth superior, of one leaf, tubular, in four or five erect segments, internally coloured and hairy, permanent. *Cor.* none. *Stam.* Filaments equal in number to the segments of the calyx, but not so long, inserted into their base, awl-shaped; anthers roundish, of two lobes. *Pist.* Germen inferior, roundish, confluent with the base of the calyx; style thread-shaped, the length of the stamens; stigma tumid, cloven. *Peric.* none. *Seed.* Nut oval, angular, coated, crowned with the permanent involute calyx, of one cell, with a solitary kernel.

Eff. Ch. Calyx superior, of one leaf, bearing the stamens. Corolla none. Nut solitary, coated, crowned with the calyx.

Obs. Our learned friend Mr. Brown proposes to separate the Cape species of this genus from the rest, perhaps even into two distinct genera; but as we cannot find sufficient grounds for this measure, we shall admit the whole here, at least till we can obtain fuller information. *Th. Colpoon*, Linn. Suppl. 161. Willd. n. 18, is of course excluded, having a *Drupa*, and a very different habit. This is described, by some one of our coadjutors, under the article *FUSANUS*. See also LEPTOMERIA.—We are enabled to add a few in its stead to Willdenow's list, but cannot adopt such as are merely named by Mr. Brown, unless where we happen to have specimens.

The whole genus is of a rigid broom-like habit; sometimes roughish, though scarcely pubescent; with simple, usually very narrow, scattered leaves; and inconspicuous green, whitish, or yellowish flowers, either clustered, spiked, or somewhat capitate.

1. *Th. linophyllum*. Bastard Toad-flax *Thesium*. Linn. Sp. Pl. 301. Willd. n. 1. Fl. Brit. n. 1. Prodr. Fl. Græc. n. 1. Engl. Bot. t. 247. Pollich Palat. v. 1. 238. Roth. in Sims and König's Ann. of Bot. v. 2. 18. (*Th. pratense*; Ehrh. Herb. n. 12. *Th. montanum*; *ibid.* n. 2. *Th. intermedium*; Schrad. Spicil. 27. *Anonymos lini folio*; Clus. Hist. v. 1. 323. *Linaria adulterina*; Ger. Em. 555.)—Stem erect, somewhat branched. Cluster

mostly compound. Bractæas ternate. Leaves linear-lanceolate. Tube of the calyx cup-shaped, very short.—Native of dry chalky hills throughout most parts of Europe, though reckoned amongst our rarer English plants, flowering in July. The root is woody, perennial, branched, crooked; whitish, sending up several erect or reclining, smooth, leafy, more or less angular, rigid, branched stems, from four to twelve inches high. Leaves numerous, alternate, linear, entire, in some degree succulent and glaucous, minutely rough at the edges, as are sometimes the angles of the stem. Clusters, rather than spikes, more or less branched, or even panicled, each branch bearing one or more flowers, either solitary at the extremity, accompanied by three lanceolate, leafy, unequal bractæas, or without bractæas, in the fork of the stalk, whose divisions bear other flowers, with one or more bractæas. The latter is the more luxuriant state of this plant, in which it has been called *intermedium* by Schrader, and *montanum* by Ehrhart; we cannot see, by original specimens, that these two supposed species differ at all, not even so as to merit Willdenow's distinction of them as varieties. Our English plant is less luxuriant, answering to Pollich's excellent description. The calyx is turbinate, having hardly any tube: its limb five-cleft, whitish, spreading, acutely five-cleft, sometimes with intermediate teeth; closely involute after flowering. Anthers yellow. Stigma white, of two knobs. Fruit hard, striated, with five angles. The herb is scarcely bitter, a little saltish. It usually grows among grass, which it so much resembles at a little distance, as not to be readily discernible. The pure air of the open hills about Bury, and similar situations, seems to suit this plant, though the soil does not much promote its luxuriance of growth.

2. *Th. ramosum*. Branched German *Thesium*. "Hayne in Schrad. Journ. v. 1. 30. t. 7." Roth in Sims and König. Ann. of Bot. v. 2. 18. Marsch. von Bieberst. Caucas. v. 1. 175. (*T. alpinum*; Pollich Palat. v. 1. 239.)—Stem erect, branched. Cluster elongated. Bractæas ternate. Leaves linear-lanceolate. Flowers three or four-cleft, with a very short, cup-shaped tube.—Native of heaths, and sandy pastures or woods, in the Palatinate, flowering at the same time as the preceding. Not having been able to ascertain this species amongst our specimens, we shall copy Pollich's description, having endeavoured to improve our specific character by the assistance of that faithful and instructive writer. "The root," says he, "is white, fibrous. Stem erect, from three inches to a foot high, round, striated, smooth, branched from the very base; the branches alternate, very short. Leaves alternate or scattered, linear-lanceolate, sharpish, entire, rather fleshy; convex on one side, flat on the other; sessile, above an inch long, three-quarters of a line wide. Flowers solitary and sessile at the ends of the very short branches, between three leaves, of which the two lateral ones are smaller than the third. There is a white roundish basis, or receptacle, on which each flower stands. The calyx is two lines in diameter, green without, white within, having but three or four segments, which spread crosswise. Anthers pale yellow. Stigma white, capitate. Evidently different from the foregoing." Pollich. He mistakes however in his reference to Linnæus, Gerard, and Haller. As to Jacquin's *Enumeratio*, 40 and 213, we have no positive means of determining, the tube of the calyx not being there described. Marschall von Bieberstein considers our English plant, above described, as belonging to this species, and not to *linophyllum*.

3. *Th. alpinum*. Alpine Tubular *Thesium*. Linn. Sp. Pl. 301. Willd. n. 2. Roth in Sims and König. Ann. of Bot. v. 2. 18. (*Th. floribus subsessilibus, pedunculis foliosis, foliis linearibus*; Gerard Gallopr. 442. t. 17. f. 1. *Th.*

THESIUM.

n. 1574; Hall. Hist. v. 2. 265.)—Stems procumbent, unbranched. Clusters simple. Bractæas ternate; the odd one very long. Leaves linear. Flowers three or four-cleft; their tube prismatic, as long as the limb.—Native of the mountains of Germany, Siberia, Switzerland, and Italy. We received it from Switzerland, and have gathered the same on mount Cenis. Haller doubted whether his plant were really distinct from *Th. linophyllum*, not adverting to the oblong angular tube of the calyx, which indeed we have not found noticed by any author, except Vahl, nor is it sufficiently indicated in Gerard's plate. That character however clearly distinguishes the *alpinum*, which may also be recognized by its numerous, short, simple, mostly procumbent, stems; narrower leaves; very unequal bractæas, the middle one being from three to five times the length of the others, and greatly exceeding the flower with its stalk. The fruit is exactly oval, copiously marked with branching ribs, but not furnished with angles. The flowers, usually four-cleft, are said by Haller to have sometimes but three segments.

4. *Th. ebraecatium*. Naked-flowered Thesium. "Hayne in Schrad. Journ. v. 1. 33. t. 7. Termin. Bot. n. 6. t. 26. f. 4." Roth in Sims and Kon. Ann. of Bot. v. 2. 18.)—Stem erect, unbranched. Cluster simple. Flowers without lateral bractæas; their tube cup-shaped, very short.—Found near Berlin, by Mr. Hayne, author of an elegant German and Latin work on botanical terminology. We have an authentic specimen from professor Schrader, though we accidentally are deficient in that fasciculus of his Journal, which contains the description of the present species. No dispute can arise as to its difference from all the foregoing. The wide shallow form of the calyx is like the two first, but the narrow foliage, and the long narrow terminal bractæas, agree with *Th. alpinum*. The total absence of the pair of smaller lateral bractæas, essentially distinguishes it from all three.

5. *Th. humile*. Dwarf Thesium. Vahl Symb. v. 3. 43. Willd. n. 3. (*Alchimilla linearis* folio, floribus et vasculis in foliorum alis sessilibus; Shaw Afric. n. 14.)—Stem erect, branched. Flowers axillary, sessile, five-cleft; their tube very short. Gathered in cultivated ground near Tunis, by Vahl, who refers hither the synonym of Shaw, applied by Linnæus, not without scruple, to his *alpinum*; from which therefore it must of course be erased. The present is said to be annual, with an herbaceous stem hardly three inches high, branched from the base; branches smooth, angular, somewhat divided, as tall as the main stem. Leaves linear, thick, numerous, acute, an inch and half long. Tube of the calyx scarcely any; not elongated as in *Th. alpinum*. Fruit globose, rugose, the size of Coriander-seed. Vahl.

6. *Th. australe*. Australian Thesium. Br. n. 1.—"Cluster simple, elongated, somewhat spiked. Partial-stalks shorter than the flower. Calyx four or five-cleft; its segments bordered longitudinally, rather longer than the tube."—Gathered by Mr. Brown, at Port Jackson, as well as in Van Diemen's island, and on the south coast of New Holland. We have seen no specimens.

7. *Th. lineatum*. Lineated Thesium. Linn. Suppl. 162. Thunb. Prodr. 45. Willd. n. 4.—"Leaves linear. Stem round, somewhat angular; leafless in the lower part; branches straight, divaricated. Flowers axillary, stalked." Linn.—Gathered at the Cape of Good Hope, by Thunberg, who, in his *Prodrômus*, defines it, "leaves lanceolate, remote; branches striated, erect." We have not seen the plant, nor does Mr. Brown mention its name.

8. *Th. squarresum*. Recurve-leaved Thesium. Linn. Suppl. 162. Thunb. Prodr. 46. Willd. n. 5.—Leaves

linear-awl-shaped, recurved. Stem round. Flowers axillary, sessile.—From the same country. Thunberg says the flowers are stalked. The younger Linnæus remarks that the recurved, or reflexed, foliage gives this plant a very squarrose aspect. It does not appear that he possessed any specimen.

9. *Th. Frisica*. Little Trailing Thesium. Linn. Mant. 213. Willd. n. 6. Thunb. Prodr. 46.—Stem decumbent. Leaves awl-shaped. Flowers spiked; densely woolly within. Fruit globose, wrinkled.—Found at the Cape of Good Hope by Koenig, who sent specimens to his preceptor Linnæus, under the new generic name of *Frisica*, by which, we presume, he meant to commemorate his own countryman Christian Friis Rottböhl; but Linnæus reduced the plant to *Thesium*. It is one of those species whose calyx is densely lined with reflexed pubescence, and of which Mr. Brown has, justifiably perhaps, made a distinct genus, on that account. Yet it has all the habit of an European *Thesium*. The little woody knobbed root sends forth numerous decumbent, simple, leafy, roundish, smooth stems, two or three inches in length. Leaves not an inch long, linear, acutely pointed; channelled above. Flowers sessile, each accompanied by two small acute bractæas. Calyx in five deep, lanceolate, acute segments, with scarcely any tube; their dense internal white woolliness did not escape Linnæus. Fruit nearly globose, much wrinkled, not so large as Coriander-seed.

10. *Th. funale*. Stringy Thesium. Linn. Sp. Pl. 302. Willd. n. 7. Thunb. Prodr. 45.—Stem with numerous long, nearly naked, branches. Leaves, and lateral bractæas, awl-shaped, very short. Flowers spiked; their segments lanceolate, densely woolly within.—Native of the Cape. The shrubby round smooth stem, with its numerous crowded upright branches, has a very rusty aspect. The little leaves are distantly scattered. The spikes are terminal, solitary, scarcely an inch long, composed of several small, crowded, not quite sessile, flowers, in structure like the last; each accompanied by one ovate, pointed, keeled bractæa, and a pair of minute, lateral, awl-shaped ones.

11. *Th. spicatum*. Large-spiked Thesium. Linn. Mant. 214. Willd. n. 8.—Stem erect, repeatedly branched. Leaves awl-shaped, minute, scattered. Flowers spiked; their segments linear, densely woolly within. Lateral bractæas lanceolate.—From the same country, growing on hills. Allied to the last, but thrice as large in almost every part, with a stout, round, straight, determinately branched stem. The leaves however are even more minute than in that species. The spikes are thick, of numerous, very densely crowded, flowers, which Linnæus defines leaves, smooth, apparently in contradistinction to those of *Th. funale*; but however smooth, or even, like that, externally, their segments, which are linear, narrow, and parallel, are full as hairy or woolly within. The outer bractæas are much dilated and rounded in their lower half; the lateral ones also are broadly lanceolate, very different from those of *funale*.

12. *Th. capitatum*. Capitulate Thesium. Linn. Sp. Pl. 302. Willd. n. 9. Thunb. Prodr. 46.—Flowers capitulate, sessile, terminal. Leaves three-edged, pointed, smooth. Bractæas ovate. Segments of the calyx strongly pointed; densely woolly within.—Native of the same country. The stem is hard and shrubby, with alternate distant branches; the upper ones gradually longer. Leaves alternate, small, awl-shaped, pointed. Heads of flowers terminal, a fresh branch shooting out from beneath each. Segments of the calyx very much pointed, and internally villous throughout their whole length. Linnæus. In his herbarium are specimens which answer to this description, though left by him with-

THESIUM.

out any specific name, he having originally described the present species in Van Royen's *Prodromus*. The younger Linnæus took these specimens for *scabrum*, with which they agree only so far as to confirm their being the *capitatum*, contracted therewith in Sp. Pl. Their leaves however can hardly be termed small, measuring near an inch in length. The *bracteas* have dilated membranous edges; fringed, as Thunberg describes them. *Calyx* with an oblong, five-angled tube. We cannot so blindly follow Willdenow, as to insert any species between this and *scabrum*.

13. *Th. scabrum*. Rough Thesium. Linn. Sp. Pl. 302. Willd. n. 13. Thunb. Prodr. 45.—Heads of flowers stalked. Leaves three-edged, pointed; their edges very rough with cartilaginous teeth.—Native likewise of the Cape. Nearly allied to the last, though undoubtedly a very distinct species. The leaves are but half as large, and remarkable for the cartilaginous teeth of their three edges. *Flower-stalks* sometimes two or three inches long, naked. *Calyx* with hardly any tube; its segments, according to Linnæus, internally villous at the tips only, but of this we are not perfectly convinced.

14. *Th. striatum*. Wand-like Thesium. Berg. Cap. 73. Linn. Mant. 214. Willd. n. 10. Thunb. Prodr. 45.—Leaves lanceolate, with a decurrent keel. Cymes terminal. *Calyx* obtuse, smooth, except at the back of each stamen.—Found at the Cape, and first described by Bergius. Linnæus originally referred the description of this author to his own *Th. capitatum*, from which scarcely any species can be more distinct. In general dimensions, and shrubby habit, indeed they are not unlike; but the leaves of the present plant are much fewer, and more distant, and the *inflorescence* totally different, being a sort of compound irregular *umbel*, or *cyme*. The *calyx* being smooth both within and without, except a slender tuft of hairs at the back of each *stamen*, as observed by Mr. Brown, reduces this species to a different section, according to that author, along with *squarrosum*, n. 8, *fragile*, n. 16, and some others. A note at the back of one of the Linnæan specimens of *Th. striatum*, gathered by Sparrmann, says "the fruit is a *drupa*, like that of *Prunus Padus*." If so, this species should seem referrible to some other genus, as *Fusanus*; yet their habits are too dissimilar.

15. *Th. umbellatum*. Umbel'd Thesium. Linn. Sp. Pl. 302. Willd. n. 11. Ait. n. 2. Pursh n. 1. (*Centaureium luteum ascyroides virginianum*; Pluk. Mant. 43. Phyt. t. 342. f. 1.)—Flowers umbellate. Leaves elliptic-oblong.—On dry hills and fields, from New York to Carolina. Perennial, flowering in June and July.—*Flowers* white. *Pursh*. Mr. Aiton records its having first been introduced into the British gardens in 1782, by the late Dr. Hope, professor of botany at Edinburgh. This is an herbaceous species, about a foot high, erect, scarcely branched, except at the top, and having more of the aspect of some annual *Euphorbia*, than of the genus of which we are treating. The leaves are scattered, on short stalks, erect, smooth, nearly oval, about an inch long. *Flowers* three or four together in small *umbels*, on slender, solitary stalks, either axillary or terminal. *Bracteas* three or four under each umbel, pale, lanceolate, deflexed. Mr. Brown says the character of the flower of this, the only American species, is between *Fusanus* and *Santalum*. Of the fruit nothing is known.

16. *Th. fragile*. Brittle Thesium. Linn. Suppl. 162. Willd. n. 12. Thunb. Prodr. 45.—Leaves three-edged, somewhat ovate, keeled, decurrent. Stem angular. Flowers axillary, sessile.—Discovered by Thunberg at the Cape of

Good Hope. We have seen no specimens of this species. It is said to have the habit of a *Salsola*, and to be extremely brittle. The leaves are so very short, that at first sight they seem to be altogether wanting.

17. *Th. paniculatum*. Panicked Thesium. Linn. Mant. 51. Willd. n. 14. Thunb. Prodr. 45.—Stem much branched; branches diffuse, panicked, angular, many-flowered. Flowers solitary, stalked. Leaves awl-shaped.—From the Cape of Good Hope.—The stem is round, shrubby, with several round primary branches, subdivided throughout into many lateral and terminal, slender, angular ones, repeatedly and irregularly cloven and forked, bearing innumerable, small, terminal, stalked, solitary flowers, each of which is subtended by four or five sharp awl-shaped bracteas, which Linnæus describes as an inferior, but not a proper, calyx. The real calyx is obtuse and five-cleft. Fruit like Corianderseed. Many of the flowers are abortive. The leaves are scattered, and for the most part very minute. Mr. Brown does not mention this species, perhaps from not having been able to examine the inside of the flowers.

18. *Th. ericoides*. Heath-like Thesium. Herb. Banks. Brown Prodr. Nov. Holl. v. 1. 353.—Stem much branched, panicked; branches erect, many-flowered. Flowers capitate. Leaves lanceolate, channelled, decurrent, acute.—Native of the Cape of Good Hope. This has a round shrubby stem, with the panicked habit, and innumerable small flowers, of many *Ericæ*. The younger Linnæus considered it very negligently with the last, and it seems to have passed undescribed, being only mentioned in Mr. Brown's work, by the apt name it bears in the Banksian herbarium. The leaves are pretty numerous, minute, spreading, concave, broad at the base; decurrent at the margins and keel. Flowers sessile, two, three, or four, in each little terminal head, accompanied by several imbricated, ovate, keeled, sheathing bracteas, partly jagged or fringed at the edges. These bracteas evince the true nature of what Linnæus terms, in the foregoing, an inferior calyx.

19. *Th. amplexicaule*. Heart-leaved Thesium. Linn. Mant. 213. Willd. n. 15. Ait. n. 3.—"Clusters terminal. Leaves heart-shaped, sessile."—Native of lofty hills at the Cape of Good Hope.—Stem rather woody, erect, somewhat angular, four feet high, smooth. Leaves alternate, sessile, clasping the stem, heart-shaped, entire, rather acute, smooth, thickish, an inch long. Clusters terminal, consisting of minute flowers, intermixed with large ovate bracteas. Linnæus. Neither Mr. Brown nor professor Thunberg mention this species. There is no authentic specimen of it in the Linnæan collection, and we are almost convinced of its being the same plant as the following. Willdenow has made a singular mistake in copying the specific character of *Th. Frisca*, see n. 9, over again, for the *amplexicaule*, which stands above it in the *Mantissa*.

20. *Th. euphorbioides*. Spurge-like Thesium. Berg. Cap. 74. Linn. Mant. 214. Willd. n. 17. Thunb. Prodr. 46. (*Planta africana frutescens, portulacæ foliis, Morgani Syrorum, ex brevi pediculo binis, similis*; Pluk. Amalth. 173.)—Stalks three-flowered, terminal. Leaves roundish-ovate, acute, fleshy. Stem shrubby, with alternate corymbose branches.—Native of the Cape of Good Hope. This was adopted from Bergius by Linnæus, without seeing a specimen, at least from that author. One is preserved in his own herbarium, on which he had written *Thesium capense*, which his son altered to *euphorbioides*, considering it as the same with the plant of Bergius. A similar specimen lies in the Banksian collection for *Th. amplexicaule*. Both names are excellent, but perhaps *euphorbioides*, as the original

original one, ought to be preferred. The plant is of a stout shrubby habit, turning black in drying. *Leaves* about the size of the finger-nail, alternate, sessile, ovate or rather heart-shaped, clasping the stem, acute, entire, fleshy, smooth, without rib or veins. *Flowers* about the tops of the alternate corymbose upper branches, enveloped in *bractææ*, like the leaves, but smaller. Tube of the *calyx* very short, and strongly angular; limb smooth within, except perhaps a few minute hairs behind the *stamens*, indicated by Mr. Brown. *Fruit* globose, chiefly angular at the top.

21. *Th. triflorum*. Three-flowered Thesium. Linn. Suppl. 162. Willd. n. 16. Thunb. Prodr. 46.—“Leaves lanceolate. Stem angular. Flower-stalks axillary, three-forked, compound.”—Gathered by Thunberg at the Cape. The *flower-stalks* are three-flowered, sometimes divided, or three-cleft, greatly divaricated. Linn. We have met with no specimen answering to this species, nor does Mr. Brown advert to it.

22. *Th. spinosum*. Spinous Thesium. Linn. Suppl. 161. Willd. n. 19. Thunb. Prodr. 45.—Leaves awl-shaped, spinous-pointed, spreading, fleshy, decurrent. Flowers axillary, stalked, solitary.—Gathered by Thunberg at the Cape. A very singular species, whose woody decumbent stem is beset with numerous, ascending, simple branches, two or three inches long, clothed with alternate, horizontally projecting, pungent leaves, one-third of an inch in length, giving the plant the aspect of an *Ulex*. *Flower-stalks* about as long as the leaves.—Mr. Brown places this in his section of such Cape species as have the *calyx* internally naked, except a slender tuft of hairs behind each *stamen*. With it ranges *squarrosium*, *fragile*, *strictum*, *spinosum*, *ericoides*, *euphorbioides*, and one unknown to us, called *spartium*. The section whose *calyx* is lined with a dense deflexed beard, consists of *Frisea*, *funale*, *spicatum*, *capitatum*, and *scabrum*, besides five species unknown to us, called *crassifolium*, *teretifolium*, *debile*, *ciliatum*, and *divaricatum*.

THESMOPHORIA, *Θεσμοφορία*, in *Antiquity*, a festival in honour of Ceres, which was celebrated by many cities of Greece; but especially the Athenians observed it with great devotion and pomp. For the ceremonies of this solemnity, see Potter, *Archæol. Græc.* tom. i. p. 403, seq. See CEREALIA and ELEUSINIA.

THESMOTHETÆ, *Θεσμοθῆται*, an appellation given to six of the nine Athenian archons; the first and chief of the nine was called, by way of eminence, *archon*; the second in dignity was called *basileus*; the third, *polemarchus*; and the other six, *thesmothetæ*: for an account of whose power and jurisdiction, see Potter, *Archæol. Græc.* tom. i. p. 77.

THESPANIS, in *Ancient Geography*, a river of Asiatic Sarmatia; the mouth of which, according to Ptolemy, lay between that of Rhembitus and the town of Azara.

THESPHATA, *Θεσφάται*, in *Antiquity*, an appellation given to oracles. See ORACLE.

THESPIA, or THESPIÆ, in *Ancient Geography*, a town of Bœotia, situated at the foot of mount Helicon, about 50 stadia from the city of Thebes. The Thebans, who destroyed this city, spared nothing but the sacred monuments, among which were the temple of Hercules, which was served by a priestess restricted to celibacy during her whole life, and the statue of that Cupid (or Cupidon), sometimes confounded with the god of love, which was only a shapeless stone as it was dug in the quarry, for thus the objects of public worship were represented in ancient times. Praxiteles is said to have formed a statue of Cupidon of Penthelic marble; and Lyfippus made one of bronze.

The Thespians reported, that the statue of Praxiteles was taken away by Caius, the Roman emperor; but others say, that it was returned by Claudius, and that Nero removed it to Rome, where it was consumed by fire. This statue was so beautiful, that, according to Cicero, Thespia was visited merely for the sake of seeing it. The Cupidon that existed in the time of Pausanias was an imitation of that of Praxiteles by Menodorus, the Athenian; but here were a Venus and Phrynê in marble, executed by Praxiteles himself. In one quarter of the city was a temple consecrated to Venus Melenis. The theatre was a beautiful structure, ornamented with a statue of Hesiod in bronze. Near it was a Victory in bronze, and a chapel consecrated to the Muses, each of which had a small statue in marble. At Thespia there was a statue of Venus in marble, made by Praxiteles.

THESPIADES, in *Mythology*, an appellation given to the Muses from the city of Thespia, where they were honoured.

THESPIÆ, in *Ancient Geography*, a town of Thessaly, in Magnesia.

THESPIANA, the name of an antidote intended for internal abscesses.

THESPIA, in *Biography*, an ancient poet, and the supposed inventor of tragedy, was born in a small borough of Attica, named Icaria, and he, as well as Sufarion, a native of the same place, appeared each at the head of a company of actors, one on a kind of stage and the other in a cart. Sufarion attacked the vices and absurdities of his time, and represented his first pieces towards the year 580 B.C. Thespias treated nobler subjects, which he drew from history: he appeared some years after Sufarion, made his first attempts in tragedy, and acted his *Alceas* in the year 536 B.C. He was followed in this species of drama by Æschylus, Sophocles, and Euripides. Thespias having observed at the festivals, in which before his time hymns only were sung, one of the fingers, mounted on a table, forming a kind of dialogue with the chorus, took the hint of introducing into his tragedies an actor, who by simple recitals, introduced at intervals, should relieve the chorus, divide the action, and render it more interesting. This innovation, together with some other liberties in which he indulged himself, alarmed Solon, the legislator of Athens, who condemned a species of composition, in which the ancient traditions were disguised by fiction. “If we applaud falsehood in our public exhibitions,” said he to Thespias, “we shall soon find that it will insinuate itself into our most sacred engagements.”

The excessive approbation and delight with which both the city and country received the pieces of Thespias and Sufarion, at once justified and rendered useless the suspicious foresight of Solon; the poets, who till that time had only exercised their genius in dithyrambs and licentious satire, struck with the elegant forms which these species of composition began to assume, dedicated their talents to tragedy and comedy. See TRAGEDY.

Thespias, according to the description of Horace, extended his plan farther than the introduction of a single actor in the intervals between the songs of the chorus, to the representation of some fable by actors on a kind of moveable stage, who alternately sung and played, with their faces stained by the lees of wine.

“Ignotum tragicæ genus invenisse Camænx
Dicitur, et plaustris vexisse poemata Thespiis,
Quæ canerent agerentque peruncti sæcibus ora.”

Art. Poet.

Some writers have mentioned three pieces of Thespias,
v. c.

viz. "The Contest of Pelias or Phorbas;" "The Sacred Youths;" and "Pentheus." Socrates says that he represented tragedies in the 61st Olympiad, long after Solon's death. Travels of Anacharsis, vol. vi. 8vo.

THESPIUS, in *Ancient Geography*, a river of Greece, in Bœotia.

THESPROTI, a people of Epirus, who inhabited Thesprotia, in the vicinity of the Ambraciates; and formed one nation with the Chaonians. They derived their name from Thesprotus, the son of Pelafgus, who was the son of Lycaon, and who was the first that conducted the Pelafgi into Epirus.

THESPROTIA, or THESPROTIS, a small country of Epirus, S. of Chaonia, having to the E. the lake Ambracius and Ambracia, and to the S. the sea. This country was watered by three rivers, which ran from W. to E., viz. Thiamis, Cocytus, and Acheron.

THESSALIA, THESSALY, a celebrated country of Greece. This country, comprising Magnesia and other small districts which have particular denominations, is bounded to the E. by the sea, to the N. by mount Olympus, to the W. by mount Pindus, and to the S. by mount Oeta. From these permanent boundaries branch out other chains of mountains and hills, that wind through the country, occasionally embracing fertile plains, which, from their form, and the manner in which they are inclosed, resemble vast amphitheatres. Opulent cities are seated on the heights that encircle these plains; and the whole country is watered by rivers falling in general into the Peneus, which, before it loses itself in the sea, flows through the famous valley of Tempé. The Aphidanus, or Apidanus, proceeded from the S. where was Dolopia, ascended northward (see PENEUS), traversed the plains of Pharfalia in the Thessaliotide, and discharged itself into the Alpheus, W. of Larissa. (See APIDANO.) The Oncheus, or Oncheones, took its rise S. of Larissa, passed by the Palus Bocbeis, and after having received the Naurus, discharged itself into the Pelafgic gulf, between Demetrius on the left and Pagasæ on the right. The Sperchius commenced S.W. in an angle which was formed by the chains of Pindus with those of mount Oeta, ascended N.E., watered Sperchium, turned to the E., and having passed Hypata, received the Achelous of Thessaly, which proceeded from mount Othrys, and being joined by the Lamina, discharged itself into the Maliac or Lamiac gulf. The country was marshy, and abounded with a variety of plants, some of which were medicinal and sanative, and others venomous and pernicious. The knowledge of their different properties caused the Thessalians to be regarded as a class of sorcerers, who possessed the art of producing supernatural effects. The principal people of Thessaly were the Æthices, situated towards the N.W., whose chief town was Oxinia, near a lake that lay between small chains of mountains:—the Pelagoni Tripoliti, in a kind of hollow territory, separated from Macedonia by a chain of mountains, called Cambrunii montes; denominated Tripolitans on account of their three towns, Dolicha, Pythium, and Azorus: in the eastern part of this territory was the Afeuris palus, or marsh Afeuri:—the Perrhæbi, lying S. of the mountains which formed this territory, and extending from W. to E., the N. of the Peneus:—S. of the Peneus, towards the W., was the Estizotis, watered by the rivers Ion and Thæus, and bounded W. and S. by mount Pindus: its most considerable towns being Gomphi, Trica, Pelinaeum, and Pharcadon:—the Pelafgiotis, towards the E., having the Peneus to the N. and commencing W. from the Apidanus, which received the Enipeus, that passed to Phar-

sal: the principal towns of this part of Thessaly were Larissa, reckoned the capital of Thessaly; Pharfala, one of the largest and most opulent towns, now Pharfalia, Scotuffa, Cranon, &c.:—the Thessaliotis being to the S. and watered by the Enipeus in the lower part of its course, and having to the S. mount Othrys, and to the S.W. Dolopia; its principal town was Melitæa upon the Enipeus:—the Phthiotis, towards the S.E., terminating in a peninsula, and watered by the Sperchius and Achelous; its principal towns were Pheræ, to the N.; Thaumaci, to the W., commanding one of the finest prospects in Greece; Alos and Lamia, towards the middle; Phalara, at the bottom of the Amalzac gulf; in the peninsula, Thebæ, Larissa, Cremaita and Echinus: at the extremity the port of Aphetæ, and S.E. Heraclea Trachina, the road from which led to the straits of *Thermopylæ*; which see. Magnesia was separated from the sea by mount Pelion: here were the towns of Demetrias and Iolcos, and S.E., on the eastern coast, the town of Magnesia, and at the extremity of the peninsula to the S.W. the town of Antium. At the bottom of the Pelafgiotic gulf were the two small islands of Deucalion and Pyrrha. Dolopia lay towards Ætolia, and contained no considerable towns. The extremity of the S.E. of Magnesia was terminated by the promontory Sepias, where the fleet of Xerxes was battered by a tempest. The town of Gonnus, at the entrance of the valley of Tempé, was the key of Thessaly on the side of Macedonia, as the post of *Thermopylæ* was on the side of Phocis. See THESSALY.

The several nations which we have recounted, as properly Thessalian, were formerly governed by kings, but after various revolutions became for the most part subject to an oligarchy. The states and the towns were independent of each other. The confederacy of the Thessalians, properly so called, was the most powerful of all, both from the number of towns pertaining to it, and from the accession of the Magnesians and Perrhæbians which were brought almost under complete subjection. There were some free cities, unconnected with any of the states. The Thessalians could bring into the field an army of 6000 horse and 10,000 infantry, exclusively of their archers, who were excellent, and who from their infancy were accustomed to draw the bow. The Thessalians are said to have been the first who managed horses with the bit, and used them in battle; and hence, it is said, originated the tradition that a race of creatures, called centaurs, half horse and half man, formerly existed in Thessaly. This country produced wine, oil, and fruit of different kinds. The land has been represented to be so rich, that the corn grew too fast, if it were not cut, or sheep turned in to graze upon it. They carried on a considerable commerce in corn. The Thessalians, though they boasted of their liberty, were the first to reduce Greeks to slavery. Amongst them they had a prodigious number of slaves, known by the name of Penestæ. These people are very hospitable to strangers, and treat them magnificently. In their dress and houses luxury is conspicuous; and at their entertainments they hire dancing girls to amuse them. They are reckoned passionate and turbulent, and very difficult to be governed; and they are reproached with insincerity and falsehood. They have cultivated poetry from their most early ages, and pretend that Thessaly gave birth to Thamyris, Orpheus, Linus, and many others who lived in the heroic age; but since that period, they have produced no writer nor any celebrated artist. They were much addicted to dancing; and in some places generals or magistrates were called chiefs of the dance. Their music observes a medium between the Doric and Ionic, and accordingly harmonizes with the character and manners of the country.

country. They have never on any occasion killed storks, and the same punishment was inflicted on a person who killed one of these birds as if he had taken away the life of a man. This law, it is said, was founded on the circumstance, that storks had freed Thessaly from the enormous serpents which formerly infested it.

THESSALICUM SÆDILE, the Thessalian chair, so called from Thessaly, where chairs of this figure were most in use: it is recommended by Hippocrates, Lib. de Art. in place of a machine for reducing a recent luxation of the shoulder-bone. The back of this chair is perpendicular to the seat, as Galen tells us, by which construction it is distinguished, and accommodated to the operation.

THESSALIOTIS. See **THESSALIA**.

THESSALON, in *Geography*, a river of Canada, which runs into lake Huron, N. lat. 49° 6'. W. long. 82° 8'.

THESSALONIANS, *Epistles to*, in *Scripture History*. See **EPISTLE**.

THESSALONICA, in *Ancient Geography*, a town of Macedonia, situated on the Thermaic gulf; and built on the declivity of a mountain in the form of an amphitheatre, the summit of which was defended by a castle of great extent. Strabo says that it was named "Therma," and that it was only a village; that Cassander augmented it considerably, and transported hither the inhabitants of some neighbouring cities, and gave it the name of Thessalonica, that of his wife, the sister of Alexander the Great. In the year 168 B.C., Macedonia was divided into four parts, and Thessalonica was the capital of the second part. Its government was regulated by magistrates, called "Political." Under the Greek empire it continued to be governed by a senate. Cicero, during his exile, passed some time at Thessalonica. This city had several divinities, and also emperors, who were objects of public worship. Jupiter was the principal; Apollo was also represented on its monuments; and the Cabiri had a temple in Thessalonica. The Cabirian and Pyrrhic games were exhibited in this city in honour of the Cabiri, and the Olympic games were celebrated in honour of Jupiter. That rich and powerful city had, for its spectacles and the amusement of the citizens, an amphitheatre for the combats of gladiators, and a circus for the public games. The emperors Valerian and Gallienus gave it the title of a colony. It had also the title of Neocorus, The modern name of Thessalonica is *Salonica* or *Saloniki*. (which see.) Although there are different routes by which goods are transported from Macedonia into the Austrian dominions, the best, says Dr. Holland in his *Travels into Albania*, &c. is through Bulgaria, by Widin and Ossovo, where it enters the Austrian territory, and is thence continued through the Bannat by Temeswar, Pest, Raab to Vienna. The goods landed at Salonica are made up in packages of 1½ hundred weight, and two of these are the load of a horse. The cavalcades for this inland journey consist often of 200 or 300, and sometimes of 1000 horses. The property so transported, at a moderate estimate, might be worth 30,000*l.* on its arrival in Germany. The time occupied between Salonica and Vienna was in general thirty-five days, exclusive of the quarantine at Ossovo, which sometimes took place. The cavalcades usually travel eight hours in the twenty-four.

THESSALY, or **JANNA**, in *Geography*, a province of European Turkey, bounded on the N. by Macedonia, on the E. by the Archipelago, on the S. by Livadia, and on the W. by Livadia and Epire, anciently called *Thessalia*, *Pelassgia*, and *Pyrrhæa*, (see **THESSALIA**), and now by the Turks *Janna*. It was sometimes annexed to Macedonia, and sometimes separated from it. The celebrated mount

Pindus, now *Messova*, or *Messo Novo*, separated it from Epirus, or a part of the present Albania. Amongst its once celebrated twenty-four mountains, the most remarkable are Olympus, Pelion, and Ossa. Here are also situated the plains of Pharfalia, and the delightful valley of Tempé. The country is extremely fertile, and retains its ancient character in this respect. It produces oranges, citrons, lemons, pomegranates, very sweet grapes, excellent figs and melons, almonds, olives, cotton, and chestnuts, which take their name from Castanea in Magnesia. The modern Thessalians are a well-made spirited people. The most remarkable places in the country are Larissa and Janna. See **THESSALIA**.

THESTIA, in *Ancient Geography*, a town of Epirus, in Acarnania.—Also, a river of the Peloponnesus, in Laconia.

THESTIDION, a town of Greece, in Thessaly.

THESTIS, a town which belonged to the Arabs.—Also, a town of Africa, in Libya.—Also, a fountain of Africa, in the Cyrenaica, near Irafra.

THETA, Θ, among the *Ancients*, one of the Greek letters. It was used as a mark on the ballots of judges, by which they condemned the person to death, it being the first letter of the word Θάνατος, *death*. Whence it had the epithet of *niger* and *infelix*, thus:

"O multum ante alias infelix litera theta."

THETES, Θητες, in *Antiquity*, the lowest class of people at Athens. Aristides repealed Solon's law by which the thetes were made incapable of bearing any office in the government.

THETFORD, in *Geography*, an ancient borough and market-town, partly in the hundred of Shropham, and county of Norfolk, and partly in the hundred of Lackford, in the county of Suffolk, England, is situated at the distance of 28 miles S.W. from Norwich, and 80 miles N.N.E. from London. It was a place of considerable consequence at an early period.

Thetford, called in the Saxon Chronicle *Theodford*, has an acknowledged claim of having been once the seat of the East Anglian kings. Being the metropolis of that portion of the heptarchy, it became subject to the ravages of the Danes, by whom it was repeatedly laid in ashes. From numerous coins, it is evident that there was a mint at Thetford from the time of Athelstan to the reign of king John. At the eastern extremity of the town are some extensive remains of fortifications, consisting of a large artificial mount, or keep, with lofty banks and deep ditches. These fortifications were probably first formed by the early kings of East Anglia, and the keep an addition, made subsequent to the Norman conquest. East of the mount is a large area, or place of arms, three hundred feet square. The mount is about one hundred feet in height, and nine hundred and eighty-four feet in circumference, at the base. The slope is extremely steep; and yet no traces remain of any path or steps for the purpose of carrying up machines or weighty ammunition.

In the Conqueror's time, Herfast having removed the episcopal see from North Elmham to Thetford, the latter became the head of the East Anglian diocese; but in the succeeding reign, the see was transferred to Norwich. The ruins of ecclesiastical and other buildings strongly point out the ancient splendour of this town. At one period it is said to have had twenty churches, answerable to the number of parishes, and eight monasteries, besides other religious and charitable foundations. But of these, the names only of some remain; and of others, a few dilapidated walls serve

to mark their scites. Of the twenty churches, three only are preserved; St. Peter's, and St. Cuthbert's, on the Norfolk side of the river; and St. Mary the Less on the Suffolk side. St. Peter's, commonly called the Black church, from its being constructed chiefly of flint, consists of a chancel, nave, two aisles, and a tower. The latter was rebuilt in 1789, when a great part of the church was also re-edified. The battlements on the south side, and the buttresses, are decorated with allusive ornaments and large letters inlaid in the flint work.

The *Nunnery* was founded by Uvius, the first abbot of St. Edmund's Bury, in the reign of king Canute; in commemoration of the number of persons who fell at Snarehill, near this town, in the sanguinary conflict between king Edmund's army and the forces under the Danish leaders Ingwar and Ubba. A few monks were placed in this monastery, which was then considered as a cell to Bury Abbey. In the year 1176, the monks, being reduced to two, resigned, by the request of the abbot of Bury, who placed in their stead a convent of nuns, who had previously resided at Lynn. At the dissolution, the revenues and scite were granted to sir Richard Fulmerston, who made this house his residence. It was afterwards let to a farmer, and some years since the greater part was taken down: a new farm-house was built of the materials, and the conventual church converted into a barn. Some of the walls, with buttresses, windows, &c. still remain.

The *Priory or Abbey* was founded by Roger Bigod, in the year 1104, for monks of the Cluniac order. This was a peculiarly privileged house; for other Cluniac monasteries were subject to have their revenues seized, on a war breaking out between England and France, because being dependant on the abbey of Clugny, in Burgundy, the monks were considered as foreigners; but the religious persons of this monastery were naturalized, and treated as other subjects of the realm. At the suppression the revenues were granted to the duke of Norfolk, and are now the property of lord Petre. The ancient gateway, constructed with freestone and black flint, with parts of the church, &c. still remain. This monastery had been the burial-place of the several noble families who had successively borne the title of earls of Norfolk.

St. Austin's Friary was founded by John of Gaunt, duke of Lancaster, in the year 1387, for friars mendicant of the Augustine order. The scite, granted to sir Richard Fulmerston, is still called the Friar's Close.

The *Monastery of St. Sepulchre* was founded in 1109, by William, earl of Warren and Surrey, for canons of the Augustine order, and additionally endowed by king Henry II. The scite is still called Canons: part of the conventual church, yet standing, has long since been used as a barn. The gate of the porter's lodge, and some other parts of the buildings, remain. Of the other four religious houses, no vestiges are now left. In the Suffolk part of the town, near St. Mary's church, is a free grammar-school. In the year 1566, sir Richard Fulmerston bequeathed property for the erection of a free-school, with dwelling-houses and salaries for a master and usher; and also habitations and weekly pensions for two poor men and two poor women. The benevolent design of the donor, however, was not carried into effect till the time of James I., when it was enacted by authority of parliament, that there should be for ever a free grammar-school and hospital; and that the master, usher, and the four poor people, should be a body politic, under the title of "The master and fellows of the school and hospital at Thetford, founded by king James the First, according to the will of sir Richard Fulmerston, kat."

Thetford, though a very ancient burgh, is comparatively a modern corporation. In the time of the Conqueror, the town was governed by a constable and other inferior officers. Not being a free burgh, it suffered greatly at times by the oppression of the officers nominated by the crown. But in the year 1573, queen Elizabeth granted a charter, by which a mayor, ten aldermen, twenty common-councilmen, a recorder, town-clerk, sword-bearer, and two serjeants at mace, constitute the corporation. The mayor for the time being is clerk of the market, and in the year after his mayoralty officiates as coroner. The corporation had also permission to send two burgesses to parliament, "provided they were discreet and honest men, and were elected at the expence of the borough." This charter was surrendered to the crown in the thirty-fourth year of Charles II., and a very imperfect one obtained in its stead. But in 1692 an order was procured from the court of chancery for cancelling the surrender, and procuring a transcript of the charter granted by Elizabeth, under which the town is at present governed. Thetford has been honoured with the presence of many of our sovereigns, particularly Henry I. and II. Several charters, granted by the former, bear date from this town. When the manor fell with the duchy of Lancaster, of which it formed a parcel, to the crown, the ancient seat of the earls Warren became the royal palace. This was rebuilt in the time of queen Elizabeth, who occasionally resided here. King James I. made it one of his hunting seats; but being disgusted with the abrupt remonstrance of a farmer, over whose lands he had been hunting, he gave the palace to sir Philip Wodehouse: it has been rebuilt, and is now the property of a private gentleman; but still bears the appellation of the "King's House." The old guildhall or council-house being in a dilapidated condition, sir Joseph Williamson, secretary of state to king Charles II., erected at his own expence the present council-chamber, and the apartment for the juries. Thetford has been much improved within the last twenty years. A new bridge has been built, the principal street paved, and several handsome houses have been erected. The navigation of the river has been attended to, and by this communication some mercantile business is transacted in the corn and coal trade. Five fairs are held annually, and a market weekly on Saturdays; but, compared with its former greatness, it is now a very inconsiderable place. The population in the return of the year 1811, was stated to be 2450, occupying 530 houses.

Near to Thetford is a mineral spring, the waters of which possess considerable virtues, though their celebrity has by no means been commensurate with their acknowledged efficacy. Thomas Paine, well known for his political and theological tracts, was a native of this town, and received his education in the grammar-school.—Blomefield's *Essay towards a Topographical History of Norfolk*, vol. ii. *Beauties of England and Wales*, vol. xi. by John Britton, *F.S.A. History, &c. of Thetford*, by Thomas Martin, 4to.

THETFORD, a town of the United States, in the county of Orange, Vermont; 10 miles N. of Hanover; containing 1735 inhabitants.

THETIS, in *Mythology*, the name of the most beautiful of the Nereids.

THEVACOURCHY, in *Geography*, a town of Hindoostan, in the Carnatic; 20 miles W.S.W. of Tiagar.

THEUDORIA, in *Ancient Geography*, a town of Achaia, from which the Macedonians were driven by the Romans.

THEUDURUM, a town of Lower Germany, on the route

route from Colonia Trajana to Colonia Agrippina, between Mederiacum and Coriovallum. Anton. Itin.

THEVEN, in *Geography*, a town of Persia, in the province of Laristan; 40 miles E. of Lar.

THEVENARD, GABRIEL VINCENT, of Paris, in *Biography*, born in 1669, became in the operas of Lulli the first singer and actor of his time. He had a tenor voice, which made the public forget that of Beaumavielle; it was sonorous, mellow, and extensive in compass. He sung a little through the throat, but by dint of art, he found the means of rendering this little defect even agreeable. His appearance on the stage was dignified, and his performance wonderful! It was to him that the present manner (1780) of speaking recitative is due. He excelled above all in singing at table; nor has he ever been surpassed in that talent, except by De Chaffé and Jeliote, who so many years delighted their friends.

He sung more than forty years at the Opera, and only retired in the year 1730. He was more than sixty years old, when, seeing a beautiful female slipper in a shoemaker's shop, he fell violently in love, unfeigned, unseen, with the person for whom it was made; and having discovered the lady, married her, after obtaining the consent of an uncle on whom she was dependent, with the assistance of many bottles of wine which they cracked together with the utmost cordiality, and which Thevenard meliorated with the charms of his voice.

He died at Paris in 1741, at the age of 72. Thevenard was the cause of the duke d'Antin quitting the management of the opera. This singer having a pension offered him for his services, found it so inconsiderable, that he refused to accept of it, saying it was only fit for his footman. The duke, piqued at this insolence, would have sent him to prison; but it having been represented to him that the public would suffer by his absence, he sacrificed to this consideration his resentment; but determining to have nothing more to do with such people, he quitted the superintendance of the opera. Laborde.

THEVENOT, JOHN, a traveller in the Levant, was born in Lorraine, and after repeated journies, died in Persia in 1667. He is said to have introduced the use of coffee into France. His "Voyage in Asia" was published in 1664, which is a work considerably esteemed, and has been often re-edited. The Amsterdam edition in 12mo., 1727, is comprised in 5 vols. *Nouv. Dict. Histor.*

THEVENOT, NICHOLAS MELCHISEDEC, a writer of travels, was born in 1621, probably at Paris, and having finished his studies, indulged his propensity for visiting foreign countries, confining himself chiefly to various parts of Europe. Some persons have given him the credit of being a great linguist, but this is disputed by Huet, who was personally acquainted with him. The result of his observations and inquiries was published in a "Collection of Voyages and Travels," comprised in 4 vols. fol. from 1663 to 1672. Thevenot was a great collector of books, consisting of more than 2000 volumes, in which the royal library, of which he was keeper, was deficient. Nointel, on returning from his embassy to Constantinople, enriched this collection by a present of his marbles, inscriptions, and bas-reliefs. He died in 1692. From various MSS. in the royal library, he had compiled "The Works of Ancient Mathematicians," an edition of which was published after his death. Moreri. Huet.

THEVET, ANDREW, a traveller and writer, was born at Angouleme in 1502; and being desirous of visiting foreign countries, he obtained, by the interest of the cardinal of Lorraine, an opportunity of going to Jerusalem. His

travels in the Levant occupied him from 1549 to 1554; and after his return to France, he accompanied the sieur de Villegaignon, in 1555, to found a colony in Brazil. In 1556 he took the habit of an ecclesiastic, and was appointed almoner to queen Catharine de Medicis. He also obtained the titles of historiographer and cosmographer royal, and died at Paris in 1590, at the advanced age of 88 years. Besides other works, he published "Cosmographie du Levant," 1554, 4to.; "Les Singularités de la France Antarctique," 1588, 4to.; and "Cosmographie Universelle," 2 vols. fol. 1575; but unfortunately his veracity is questionable. Moreri.

THEVESTE, TIFFESTE, in *Ancient Geography*, a town of Africa, situated on a delightful plain in the interior of the country, on the banks of a river, E. of Sigus, and E.S.E. of Cirta. In Anton. Itin. this town has the title of a Roman colony, and is placed on the route from Carthage to Cæsarea, between Ammedara Colonia and Attaba.

THEVET. See TEBET.

THEVETIA, in *Botany*, a name given by Linnæus, in his *Hortus Cliffortianus* 75, to a genus distinguished by Plumier, and other authors, under the American appellation of *Ahouai*. The person commemorated by the above name was André Thevet, a French monk, who travelled to Brazil, of which he published an account in 1554, under the title of *Les Singularitez de la France Antarctique, autrement nommée Amerique*, &c. Of this book there are several editions, with rude wooden cuts, and some accounts of plants, amongst which the *Ahouai* is, for the first time, described. The author, according to De Theis, died in 1590, about the age of eighty-eight. Haller says he has injudiciously applied passages in the writings of the ancients to the productions of the new world; and that he has described many countries which he never visited. Linnæus himself appears not to have been satisfied with the honour he was conferring, for he says he should not be displeased with any person who might change this name for another. He subsequently retained it as a specific name only, when the genus in question was sunk in his own CERBERA. See that article.

THEU-PROSOPON, in *Ancient Geography*, a promontory of Phœnicia, between Tripolis and Botrys. Mela calls it Euprosopon.

THEURGY, θεουργία, a name which the ancients gave to that sacred part of magic which we sometimes call *white magic*, or the *white art*.

The word is formed from θεός, *God*, and εργον, *work*; *q. d.* the art of doing divine things, or things which God alone can do: or the power of working extraordinary and supernatural things, by invoking the names of God, saints, angels, &c.

Accordingly, those who have written of magic in the general, divide it into three parts: the first of which is called *theurgy*, as operating by divine or celestial means; the second, *natural magic*, performed by the powers of nature; and the third, *necromancy*, which proceeds by invoking dæmons.

This theurgy, or pretended art of so purging and refining that faculty of the mind, which receives the images of things, as to render it capable of perceiving the dæmons, and of performing many marvellous things by their assistance, was adopted by the disciples of Ammonius towards the close of the second century. Ammonius, the founder of the sect of modern Platonics (see PLATONISM), with a view of reconciling the popular religions of different countries, and particularly the Christian, with his own system, turned into mere allegory the whole history of the gods, and maintained that those beings, whom the priests and people dignified with this

title, were no more than celestial ministers, to whom a certain kind of inferior worship was due. He acknowledged Christ to be a most excellent man, the friend of God, and the admirable theurge; but denied that it was his intention entirely to abolish the worship of *dæmons*, and of the other ministers of divine providence; affirming, on the contrary, that he merely purified the ancient religion, and that his followers had manifestly corrupted the doctrine of their divine master. Mosh. Eccl. Hist. vol. i. 8vo.

THEUTIS, in *Ancient Geography*, a small town of Arcadia, S. of the river Lodon, and near that of Tuthoa.

THEUX, in *Geography*, a town of France, in the department of the Ourthe; 5 miles N.W. of Spa.

THEXIS, a word used by the old medical writers, sometimes for wounds made by puncture with small instruments, and sometimes for the operation of the future, or the sewing together the lips of a wound, to make it heal with a less fear.

THEYA, in *Geography*. See **TEYA**.

THEYE-CHEEKE LAKE, a lake of North America. N. lat. 65°. W. long. 109°.

THEYE-NOYE-KYED LAKE, a lake of North America. N. lat. 64° 10'. W. long. 108°.

THEYHOLEKYED LAKE, a lake of North America. N. lat. 62°. W. long. 102° 5'.

THEYSSE, a river which rises in the E. part of Hungary, on the borders of Poland, and runs into the Danube; 19 miles N.W. of Belgrade.

THEZE, a town of France, in the department of the Lower Pyrenees; 12 miles N. of Pau.

THIA, or **DIVINE**, in *Ancient Geography*, an island which, A.D. 46, was under the empire of Claudius. It was one of the Cyclades, situated between Thera and Therasia. It either disappeared, or was reunited to that of Hiera towards the year 726, on occasion of a violent eruption which took place at that time.

THIA, a town of Cappadocian Pontus, upon the route from Trapezunte to Satala, between Zigana and Sedilcapisonti. Anton. Itin.

THIACAR, in *Geography*, a town of Thibet; 75 miles S.E. of Lassa.

THIAGOLA, in *Ancient Geography*, a name given to the most northerly mouth of the Danube, and to the marsh which it forms before it runs into the Euxine sea.

THIAN, in *Geography*, a town of the county of Tyrol; 13 miles W. of Bolzano.

THIAR, in *Ancient Geography*, a town of Spain, upon the route from Tarragona to Castula, between Illicis and Carthage. Anton. Itin.

THIAUCOURT, in *Geography*, a town of France, in the department of the Meurthe; 7 miles W. of Pont-à-Mousson.

THIAUMA, in *Ancient Geography*, a town of Albania, between the rivers Cæsius and Gerrus.

THIBAUT VI., in *Biography*, count of Champagne and king of Navarre, deserves to be recorded as one of the earliest French song-writers. In 1234 he succeeded to the crown of Navarre on the death of his maternal uncle. Upon his return from the East, whither he went as one of the crusaders, he cultivated literature, and particularly poetry. He died at Pampelona in 1253, having acquired the somewhat inconsistent titles of the Great and the Song-maker. Under the latter character he obtained permanent reputation, degraded, however, by the occasional licentiousness of his imagery. He was the first, it is said, who blended masculine with feminine rhymes:—a capital invention in French versification. Moreri. *Nouv. Dict. Hist.*

The songs of this prince are placed by some at the head of those that have been preserved in the French language, as those by Guillaume IX., duke of Aquitaine, are in that of Provence. There were indeed songs written in both languages before these princes had done poetry the honour to make it their favourite amusement; but the chief part of those of higher antiquity than the time of these patriarchs of Provençal and French versification are either lost, or thought of little value.

This prince was contemporary with Philip Augustus, and Lewis VIII. and IX., which last prince he accompanied to the Holy War. It has been said by several historians that he was much captivated by the charms of queen Blanche of Castile, mother of St. Lewis, to whom many of his songs were addressed; but this point of history has been disputed with great zeal by M. l'Évêque de la Ravallière, editor of Thibault's poems, which he published in 1742, with notes, in 2 vols. 12mo. and a history of the revolutions, in the French language, from the time of Charlemagne to that of St. Lewis, together with an Essay on the Antiquity of French Songs. This learned prelate has defended the honour of queen Blanche with his pen, five hundred years after her decease, with as much prowess and true chivalry, as the most valiant champion of injured innocence could have done with his sword and lance, had he been animated by the presence of that princess, and the heroism of the times in which she lived.

“*Les Grandes Chroniques de France*” tell us that Thibault, at the age of thirty-five, having conceived a violent and hopeless passion for queen Blanche, was advised by wife and prudent counsellors to apply himself to music and poetry, which he did with such success, that he produced “the most beautiful songs and melodies that have ever been heard.” Fauchet *Des Anciens Poetes François*.

Two airs by Thibault may be seen in Burney's *General History of Music*, from the Vatican collection of Provençal songs in Gregorian notes, without bars or base; and given afterwards in modern notation, with a base, and an English version of the words.

THIBERVILLE, in *Geography*, a town of France, in the department of the Eure; 9 miles E. of Lisieux.

THIBET, or **TIBET**, pronounced *Tibbet* and *Tibt* in Bengal, and called by its own inhabitants *Puë*, or *Puë-koachim*, *puë* signifying *northern*, and *koachim*, *snow*, that is, the snowy region of the North, is a country of Asia, of which our knowledge, principally obtained at a very recent period, is still very imperfect. We have no evidence that the ancients ever penetrated the snowy mountains of Tibet. It seems to have been in some measure disclosed to the Portuguese, in their commercial intercourse with the East Indies; and the name of it was known to Marco Paolo and other travellers of the 12th and 13th centuries. Accordingly, Tibet seems to have been the southern part of their Tangut. Paolo indeed describes the province of “*Tebeth*,” as containing eight kingdoms, with many cities and villages, and as being a mountainous country, which produced some gold and spices, a large breed of dogs, and excellent falcons. But we have no geographical nor statistical account of this country upon which we can depend previously to the last century; and even now our knowledge of it is very partial and defective. About the year 1715, the emperor of China, as we learn from Du Halde, being desirous of obtaining a map of Tibet, sent two lamas, who had studied geometry, for this purpose. These lamas drew a map, from Sining, in the province of Shen-si, to the sources of the Ganges, which was afterwards examined by the Jesuits, and improved. This map is published in the *Atlas of Du Halde*, and has been followed, with few variations, by our modern geographers.

THIBET.

Its authority is doubtful, its accuracy very suspicious, and the information it affords concerning kingdoms, states, and provinces, as well as particular places, very limited and unsatisfactory. According to our most recent maps, Tibet extends from about the 75th to the 101st degree of longitude, which, in the latitude of 30°, may be about 1350 geographical miles. The breadth may be regarded as extending from the 27th to the 35th degree of latitude, or about 480 geographical miles. It appears, however, from the testimonies of two intelligent travellers, Mr. Forster and Tiefenthaler, that the northern boundary of Tibet may be safely extended two degrees farther than it appears in our best maps, in which there is no portion of Great Tibet to the N.E. of Cashmir. Major Rennell moved it one degree farther to the north than D'Anville's boundary in lat. 34°, and Pinkerton thinks that he might safely have extended it at least 3°. The northern boundary of Tibet, according to the Russians, is Mus Tag, and they place that range in 38°. By adding 2° to 35°, we obtain an addition of 120 geographical miles to the number of 480 above stated.

Tibet, according to Mr. Bogle's account (Phil. Trans.) begins properly from the top of the great ridge of the Caucasus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to the dominions of the Russian empire. He says, that having once attained the summit of the Bootan mountains, you do not descend in an equal proportion on the side of Tibet; but continuing still on a very elevated base, you traverse vallies which are wider and not so deep as the former, and mountains that are neither so steep, nor apparently so high. On the other hand, he represents it as the most bare and desolate country he ever saw; and the climate as extremely severe. According to Mr. Turner, the boundaries of Tibet and Bootan are separated by the lofty range of mountains called Soomoonang, and are marked by a long row of little inscribed flags, fixed in rude heaps of stones, and fluttering in the wind. These, at the same time, are supposed to operate as a charm over the Dewtas, or "genii loci," who are paramount here. No mountain is thought to be wholly exempt from their influence; and they range chiefly in the most elevated regions, where, drenched with dews, and worried with tempestuous weather, they are supposed to deal around them, in ill humour, their most baneful spells, to harass and annoy the traveller.

Tibet is sometimes divided into three parts, *viz.* Upper, Middle, and Lower. Upper Tibet comprises chiefly the province of Nagari, abounding with tremendous rocks and mountains, always covered with snow. The countries of Lata or Ladak (Latac) and Breguiong or Bramascion (perhaps Sirinagur) probably constitute a portion of Upper Tibet, as well as Nagari. Middle Tibet contains the provinces of Shang, Ou, and Kiang; and those of Lower Tibet are Takbo, Congbo, and Kahang. Many of these provinces are again subdivided: *e. g.* Nagari, which is considered as a kingdom consisting of three departments, Sanghar, Pourang, and Tamo (Dam or Daum). Shang is on the W. bounded by Nipal. The province of Ou contains Lahassa or Lassa, the capital of Tibet. Kiang lies to the N. (or N.E.) of Ou, and is inhabited by a mixture of Tibetians and Monguls in tents. Kahang is on the S.E. bordering on the Birmans, and is divided into twelve departments. To these we must add the wide region of Amdoa, if it be not the same with Kahang, the natives of which speak the Chinese language. The country of Hor lies between Tartary and the provinces of Nagari and Kiang, and seems to be the Hohonor of our maps. Our *Bootan* (which see) is called by the natives Decco or Takbo; and the countries W. of it, *viz.* Moringa or Morung, Mocampour, Nipal, Gorca,

and Kamaoon, are not considered as parts of Tibet. On the western side, high mountains, covered with perpetual snow, and terrible avalanches, have prevented the access and invasions of the Persians and the conquerors of Bucharia; while the deserts on the N.E. have proved ineffectual barriers against the Monguls and Eluts. Travellers have also been prevented from exploring this quarter by the western mountains, so that it is even now little known.

According to the topography, compiled from the papers of Pinnabilla, a Capuchin friar, who died in 1747, and was buried at Patan, by father Giorgi, in a work published at Rome in 1762, Tibet is bounded on the E. by China and Tarcenton, a province abounding with tea, and, since the year 1720, incorporated with the Chinese empire; on the S. by Bengal, Lotenke, Altibary, Mon, Brukpa, Lhoba, Lhokhaptra, Sciapado, and Bha; on the W. by Cashmir, Nepkal, and Moronga; and on the N. by Great Tartary, the Uzbeks, Cashur, and Jonkar, as far as Jerkend and Cokonor or Kokonor. The kingdoms and provinces in this topography are enumerated by Pinkerton, *ubi infra*.

The government of Tibet has been considered as ecclesiastical or spiritual; though the lamas were accustomed to appoint a "tipa," or secular regent, a right which has been probably transferred to the Chinese emperor. This officer resides at Lassa the capital, and he is invested with the government and supreme controul over the whole country. Mr. Turner, however, is of opinion, that the temporal authority of the lamas may again recover its former dignity and splendour. Bootan, which is generally considered as a feudatory province of Tibet, has a raja or prince called Daab, of no very permanent or extensive authority. The laws must, like the religion, bear some affinity to those of the Hindoos.

The lama of Tibet was the Prester John of the middle ages, if he were not some Nestorian khan; and the appellation was unaccountably transferred by Portuguese ignorance to the emperor of Abyssinia. (See PRESTER JOHN.) In the time of Marco Paolo, Tibet, having been ravaged by the Monguls, was almost desolate. For some time this country had been subject to secular kings, called Tfan Pa; and the lama resided at Lassa, with a power resembling that of the spiritual prince of Japan. According to Giorgi, the succession of kings and lamas commences about 1340 years B.C. but about 1100 years after Christ the Chinese emperor gave to a celebrated lama the regal power. Those Monguls, called Eluts, conquered the secular prince, and transferred the whole power to the lama. (See Du Halde, iv. 50.) In 1792, the Nipalese, having committed great ravages in Tibet, the Chinese emperor sent an army to protect the lama; in consequence of which the Chinese established military posts on the frontiers, so that the intercourse between their country and Bengal is now precluded. The revenues of the lama and of the secular princes are trifling; nor is it likely that Tibet can ever aspire to any political importance.

Some have said, that the religion of Tibet is a corrupted Christianity; and even father Disiderii, a Jesuit, who visited the country about the beginning of the last century, thinks he can resolve all their mysteries into ours; and he asserts that they have a good notion of the Trinity, since, in their addresses to the Deity, they say as often koneiok-oik in the plural, as koneiok in the singular, and with their rofaries pronounce these words, Om, Ha, Hum. Of these whimsical conjectures we shall say no more, but pass on to observe, that the religion of the Tibetians seems to have derived its origin, says Turner, (*ubi infra*) from a disciple of Budh, who first broached the doctrine which now prevails over the wide extent of Tartary. It is reported to have received its earliest admission

admission in that part of Tibet bordering upon India, (which from hence became the seat of the sovereign lamas,) to have traversed over Mantchew Tartary, and to have been ultimately diffeminated over China and Japan. Though it differs from the Hindoo in many of its outward forms, yet it still bears a very close affinity with the religion of Brahma in many important particulars. The principal idol in the temples of Tibet is Mahamoonie, the Budha of Bengal, who is worshipped under these and various other epithets throughout the great extent of Tartary, and among all the nations to the eastward of the Berhampooter. In the wide extended space over which this faith prevails, the same object of veneration is acknowledged under numerous titles; among others, he is styled Godama or Gowtama, in Assam and Ava; Samana, in Siam; Amida Buth, in Japan; Fohi, in China; Budha and Shakamuna, in Bengal and Hindoostan; Dherma Raja and Mahamoonie, in Bootan and Tibet. Durga and Kali; Ganeish, the emblem of wisdom; and Cartikeah, with his numerous heads and arms, as well as many other deities of the Hindoo mythology, have also a place in their assemblage of gods.

The same places of popular esteem or religious resort, are equally respected in Tibet and in Bengal; Praag, Cashi, Durgeedin, Saugor, and Jagarnaut, are objects of devout pilgrimage; and loads of the sacred water taken from the Ganges, have been seen travelling over these mountains, (which, by the bye, contribute largely to its increase,) upon the shoulders of men, whom enthusiasts have deemed it worth their while to hire at a considerable expence for so pious a purpose.

As far as can be judged respecting their ritual or ceremonial worship, it differs materially from the Hindoo. The Tibetians assemble in chapels, and unite together in prodigious numbers, to perform their religious service, which they chant in alternate recitative and chorus, accompanied by an extensive band of loud and powerful instruments. So that, whenever these congregations were heard, they forcibly recalled to remembrance, both the solemnity and sound of the Roman Catholic mass.

The instruments made use of were all of an enormous size. Trumpets above six feet long; drums stretched over a copper cauldron, such as are termed *nozbut* in Hindoostan; the gong, a circular Chinese instrument of thin hammered bell-metal, capable of producing a surprising sound; cymbals, hautboys; and a double drum, shallow, but of great circumference, mounted upon a tall, slender pedestal, which the performer turns with great facility, striking either side with a long curved iron, as the piece requires a higher or a lower tone: these, together with the human tibia, and sea-conch, a large species of the buccinum, compose, for the most part, their religious band. Harsh as these instruments, individually taken, might sound to a musical ear, yet when joined together in unison with the voices of two or three hundred boys and men, managed with varying modulation, from the lowest and softest cadence to the loudest swell, they produce to the ear an effect extremely grand.

Other musical instruments are in the hands of the people of Tibet.

Among the Tibetians, says Mr. Turner, all is system and order. The mind readily obeys the superiority it has been accustomed to acknowledge. A sovereign lama, immaculate, immortal, omnipresent, and omniscient, is placed at the summit of their fabric. He is esteemed the vicegerent of the only God, the mediator between mortals and the supreme. They view him only in the most amiable light, as perpetually absorbed in religious duty; and, when called to bestow attention on mortal beings, as employed only in the benign office of distributing comfort and consolation by his

blessing, and in exercising the first of all attributes, forgiveness and mercy. He is also the centre of all civil government, which derives from his authority all its influence and power. At the same time that he is the soul which animates their whole system, a regular gradation, from the most venerated lama, through the whole order of Gylongs to the young novice, is observed with rigid severity.

The inferior gradations from the president of a monastery, who is always styled lama, in addition to the name of the station to which he belongs, are Gylong, Tohba, and Tuppa. See GYLONG, TESHOO-LOOMBOO, TOHBA, and TUPPA.

The nation is divided into two distinct and separate classes, those who carry on the business of the world, and those who hold intercourse with heaven. No interference of the laity ever interrupts the regulated duties of the clergy. The latter, by mutual compact, take charge of all their spiritual concerns; and the former, by their labours enrich and populate the state.

In Tibet there are two sects, distinguished by the appellations of Gylookpa and Shammar, but the external appearance, or dress of both, is similar, except the distinction in the colour of the cap; the Gylookpa having adopted yellow, the Shammar red; a circumstance which is strictly attended to, on all occasions of ceremony. Three lamas are placed at the head of each sect; Dalai lama, Teshoo lama, and Taranaut lama, preside over the Gylookpa, who have their residence at Pootalah, Teshoo-Loomboo, and Kharka. This sect prevails over the greatest part of Tibet, and a division of the same is said to be established in a province of the Decan, called Seurra or Serrora.

In like manner, three lamas also, lam' Rimbochay, lam' Sobroo Nawangnamghi, and lam' Ghassatoo, preside over the Shammar; these have their residence in Bootan, in separate monasteries, but, from the limited extent of that country, at no great distance from each other. The principal of the Shammar sect in Tibet is styled Gongfo Rimbochay, and has his residence at Sakia.

The Tibetians are actuated by an ardent spirit of devotion; and they attribute the merit of every thing great, or singularly beneficial, to the agency of some supernatural being. It is the custom in Tibet to preserve entire the mortal remains of their sovereign Lama only; every other corpse is either consumed by fire, or given to be the promiscuous food of beasts and birds of prey. As soon as life has left the body of the Lama, it is placed upright, sitting in an attitude of devotion, the legs being folded before him, with the instep reaching upon each thigh, and the soles of the feet turned upwards. It is the practice here to cover the bodies of men, found dead in the fields, with clods of earth, which the rains gradually dissolve and incorporate, forming the loose mass into a compact hillock. This always attracts the same respect, and passengers continue to add to the heap, long after all traces of the body are lost, and its existence forgotten. Thus also the piety of the Tibetians offers a similar rite to the bodies of those whom chance may have led to the spot, where the fragment lay at the instant of its fall, though the fatal effects of it may not have been certainly known.

A tribute of respect is paid, in this region, to the manes of the dead in various ways. The sovereign lamas are deposited entire, in shrines prepared for their remains, which ever after are looked upon as sacred, and visited with religious awe. The bodies of inferior lamas are usually burnt, and their ashes preserved with great care in little metallic idols, which have places assigned them in their sacred cabinets. Common subjects are treated with less ceremony;

THIBET.

mony; some of them are carried to lofty eminences, where, after having been disjointed, and the limbs divided, they are left a prey for ravens, kites, and other carnivorous birds. Others, with less respect, are committed to the usual receptacle of the dead. The last, but less frequent, mode of disposing of the dead, is committing them to the waters of the river. Burial, that is, inhuming the corpse entire in the earth, is altogether unpractised.

On one side of the monastery of Teshoo-Loomboo is the place to which they convey their dead. It is a spacious area, inclosed on one part by a perpendicular rock, and on the others by lofty walls, raised probably with a view to exclude from public observation, the disgusting objects contained within them. At the top it was totally uncovered, so as to be perfectly open to the birds; and at the bottom a narrow passage was left through the walls, near their foundation, for the sole purpose of admitting dogs, or other beasts of prey. On the rock above, a platform overhung the inclosure, which had been constructed for the convenience of precipitating the dead bodies with greater ease over the walls, into the area. And here, the only rites performed, in honour of the dead, were merely such as tended to facilitate the destruction of the body by dogs or birds of prey. But though this was the general receptacle, yet there were some who declined the use of it, and conveyed their friends to the summit of some neighbouring hill, where they disjointed and mangled the dead body, that it might become a more easy prey to carnivorous birds. Hence it was concluded that there was a strong prejudice in their minds of some idea of pollution attached to "being given to the dogs," which was sufficient to create a preference of the contrary practice. In Tibet, as well as in Bengal, an annual festival is kept in honour of the dead.

The Tibetians are much addicted to superstition; and accordingly they lay great stress on lucky and unlucky days. They also pay great respect to the professors of astrology. Hence we find no prudent traveller ever attempting to undertake a journey, without previously appealing to this authority, and endeavouring to obtain an auspicious presage. The same signal of favour is deemed indispensably requisite in every important enterprise, and the same wary circumspection enters equally into all the more minute concerns of domestic life. The union of the sexes, and the giving names to infants, are neither of them events to be accomplished without a regular appeal to the same decisive oracle. This science is also regarded in the construction of their almanacs. Their year, which is lunar, consists of 12 months, each month having 29 days; and the days are reckoned from the appearance of the new moon, in regular succession, till it shews itself again. The parts of the days are, evening, night, morning, and noon: and their computation of time is conformable to the general practice of the East, by a cycle of 12 years. The art of printing is said to have been very anciently practised in Tibet; but it has hitherto been principally appropriated to sacred works, and to the service of learning and religion. Their books are printed with blocks of wood, on narrow slips of thin paper, fabricated from the fibrous root of a small shrub. The printed and written letters appropriated to works of learning and religion, are called "uchen;" and those of business and correspondence are called "umin." The Gylongs, or priests, pass through a regular education. As for the language of Tibet, its origin is not satisfactorily ascertained. Du Halde reports, that it is the same with that spoken by the people of Sifan, on the frontiers of China; but as this province is sometimes included in Tibet, this information is vague and indeterminate. Their cha-

acters, says sir William Jones, are apparently Indian, but their language has now the disadvantage of being written with more letters than are ever pronounced; for, although it was anciently Sanscrit and polysyllabic, it seems at present, from the influence of Chinese manners, to consist of monosyllables, to form which, with some regard to grammatical derivation, it has become necessary to suppress, in common discourse, many letters which we see in their books; and thus we are enabled to trace in their writings a number of Sanscrit words and phrases, which, in their spoken dialect, are quite undistinguishable.

A singular custom prevails in this country, which may be called polyandry. One female associates her fate and fortune with all the brethren of a family, without any restriction of age or of numbers. The choice of a wife is the privilege of the elder brother; and it is said, that a Tibetan wife is as jealous of her connubial rites, though thus joined to a numerous party of husbands, as the despot of an Indian zennana is of the favours of his imprisoned fair. The business of propagating the species is abandoned to mere plebeians; and marriage seems to be considered rather as an odium and a burden. The influence of this custom on the manners of the people is not found to be unfavourable. Humanity and gentleness of disposition are the constant inheritance of a Tibetan. Mr. Turner says that he never saw these qualities possessed by any people in a more eminent degree. Without being servilely officious, they are always obliging; the higher ranks are unassuming; the inferior, respectful in their behaviour; nor are they at all deficient in attention to the female sex; but, as we find them moderate in all their passions in this respect, also their conduct is equally remote from rudeness and adulation. Comparatively with their southern neighbours, the women of Tibet enjoy an elevated station in society. To the privileges of unbounded liberty, the wife here adds the character of mistress of the family, and companion of her husbands. The company of all, indeed, she is not at all times entitled to expect. Different pursuits, either agricultural employments or mercantile speculations, may occasionally cause the temporary absence of each; yet whatever be the result, the profit of the labourer flows into the common store; and when he returns, whatever may have been his fortune, he is secure of a grateful welcome to a social home. The men are generally stout, having in a degree the Tataric features, and the women are of a ruddy brown complexion, heightened like the fruits by the proximity of the sun, while the mountain breezes bestow health and vigour.

The ceremonies of marriage are neither tedious nor intricate in Tibet. Their courtships are carried on with little art, and quickly brought to a conclusion. The elder brother of a family, to whom the choice belongs, when enamoured of a damsel, makes his proposal to the parents. If his suit is approved, and the offer accepted, the parents, with their daughter, repair to the suitor's house, where the male and female acquaintance of both parties meet and carouse for the space of three days, with music, dancing, and every kind of festivity. At the expiration of this time the marriage is complete.

Tibet is thinly scattered with inhabitants, on account of its mountainous surface and the severity of its climate; nor can any accurate estimate be made of its population. From some circumstances it has been conjectured, that upon the whole it cannot be less than half a million. Giorgi, indeed, or rather Pinnabilla, from whom he deduces his statement, computes the number of inhabitants in 1730 at 33 millions, and the soldiers at 690,000; but both these numbers are most extravagantly exaggerated; for Tibet has
been

been often conquered by the Chinese with armies not exceeding 40,000 men. The singular custom of polyandry, already mentioned, seems adapted to check the progress of population, the superabundance of which, in an infertile country like Tibet, would be one of the greatest calamities, as it must produce eternal warfare or internal want.

Bootan and Tibet exhibit a very remarkable contrast in their external appearance. Bootan presents to the view nothing but the most mis-shapen irregularities; mountains covered with eternal verdure, and rich with abundant forests of large and lofty trees. Almost every favourable aspect of them, coated with the smallest quantity of soil, is cleared and adapted to cultivation, by being shelved into horizontal beds: not a slope or narrow slip of land between the ridges lies unimproved. There is scarcely a mountain, whose base is not washed by some rapid torrent, and many of the loftiest bear populous villages, amidst orchards and other plantations, on their summits and on their sides. It combines in its extent the most extravagant traits of rude nature and laborious art.

Tibet, on the other hand, strikes a traveller, at first sight, as one of the least favoured countries under heaven, and appears to be in a great measure incapable of culture. It exhibits only low rocky hills, without any visible vegetation, or extensive arid plains, both of the most stern and stubborn aspect, promising full as little as they produce. Its climate is cold and bleak in the extreme, from the severe effects of which the inhabitants are obliged to seek refuge in sheltered valleys and hollows, or amidst the warmest aspects of the rocks. Yet perhaps Providence, in its impartial distribution of blessings, has bestowed on each country a tolerably equal share. The advantages that one possesses in fertility, and in the richness of its forests and its fruits, are amply counterbalanced in the other by its multitudinous flocks and invaluable mines. As one seems to possess the pabulum of vegetable, in the other we find a superabundance of animal, life. The variety and quantity of wild fowl, game, and beasts of prey, flocks, droves, and herds in Tibet, are astonishing. In Bootan, except domestic creatures, nothing of the sort is seen. It has been asserted that Tibet was, in remote times, almost totally inundated; and the removal of the waters that covered its surface is ascribed to the miraculous interposition of some object of their worship, whose chief temple is reported to be at Dungeedin, Gya. In this traditionary belief we may possibly discover some traces of the universal deluge; though the tradition be obscured by fable and disfigured by a mixture of absurdity. In the temperature of the seasons in Tibet, a remarkable uniformity prevails, as well as in their periodical duration and return. The same division of them takes place here, as in the more southern region of Bengal. The spring is marked from March to May, by a variable atmosphere; heat, thunder-storms, and occasionally with refreshing showers. From June to September is the season of humidity, when heavy and continued rains fill the rivers to their brim, which run off from hence with rapidity, to assist in inundating Bengal. From October to March, a clear and uniform sky succeeds, seldom obscured either by fogs or clouds. For three months of this season, a degree of cold is felt, far greater perhaps than is known to prevail in Europe. Its extreme severity is more particularly confined to the southern boundary of Tibet, near that elevated range of mountains which divides it from Assam, Bootan, and Nipal. The summits of these are covered all the year with snow, and their vicinity is remarkable, at all seasons, for the dryness of the winds. The range is confined between the twenty-sixth and

twenty-seventh degrees of northern latitude. During the winter, a practice is adopted in the neighbourhood of these mountains, similar to that in use in the coldest parts of North America, but in some respects more complete. It is that of preparing meat and fish for carriage, by the action of extreme cold. This practice, however, seems to be confined to the preservation of mutton alone, which is a very simple process, and requiring no use of salt. The Tibetians generally use that which is recently killed in a raw state, without any previous cookery.

Among the valuable and useful animals of Tibet, which are musk-deer, horses of a small size, goats yielding the hair that is manufactured into shawls, and cattle that are diminutive, to which we may refer the yak of the Tartars, their breed of sheep claims a distinguished rank. Of these the flocks are numerous, and upon them they chiefly depend for their winter food. A peculiar species, thought to be indigenous to this climate, is marked almost invariably by black heads and legs. Their size is small, their wool is soft, and their flesh, says Mr. Turner, is the finest mutton in the world. The wool affords material for one of their principal manufactures. (See IJHANSJA-JEUNG.) Their skins and those of the lambs are cured with the wool on, and constitute a valuable article for winter garments, and for foreign traffic.

The soil and climate of Tibet are very unfavourable to any kind of exertion and activity that have for their object the cultivation of the land, but from time immemorial it has been the resort of merchants. Commerce, however, has been very languidly encouraged. The form of government, which is arbitrary, is inimical to industry and enterprise. In Tibet, and also in Bootan, the first member of the state is the chief merchant; and his station and power of controul give him great advantages over the common adventurer; and of course by this monopoly of the sovereign, emulation is restrained and suppressed.

Although, as we have said, the nature of the soil prohibits agriculture; yet the vales on the approach of winter being laid under water, they are ploughed and sown in spring, and the crops are matured by frequent showers and a powerful sun. The autumn being clear and tranquil, the harvest is long left to dry on the ground; and when sufficiently hardened is trod out by cattle. The course of cultivation is wheat, peas, and barley; rice being confined to a more southern soil. Nevertheless, the country abounds with commodities, which in different circumstances would give spirit and extent to commercial transactions, whilst they are languishing in sloth, or exhibiting every indication of poverty. The trade with Bengal was formerly not inconsiderable; but this has been interrupted and diminished by the commotions which have long distracted the kingdom of Nipal, which was the only known channel of communication. Bengal transmitted to Tibet, broad cloth, chiefly of inferior quality, and of yellow and scarlet colours; some few trinkets, such as snuff-boxes, smelling-bottles, knives, scissars, and optic-glasses; and spices, particularly cloves and nutmegs; sandal wood, pearls, emeralds, sapphires, lapis lazuli, coral, jet, amber, shells, cloths, leather, tobacco, indigo, and otter-skins; and it received from Tibet, gold-dust, musk, and tincal. The articles of trade next in importance, amongst the natural productions of Tibet, are goats' hair and rock-salt. Bootan, Nipal, Bengal, and Hindoostan, are supplied with tincal from Tibet. The hair of the goats is carried to Cashmere, where it is manufactured into shawls. The demand for salt is in the consumption of Nipal and Bootan.

The trade from Tibet to Bootan consists of gold-dust; tea,

TIBET.

tea, woollen cloths, and salt; from Bootan to Tibet, the articles are English broad cloth, Rungpore leather, tobacco, coarse cotton cloths, &c. paper, rice, sandal wood, indigo. Tibet sends to Luddauk, the mart between Cashmere and Teshoo-Loomboo, the fine hair of goats, and receives in return gamboge, shawls, dried fruits, as apricots, raisins, currants, dates, almonds, and saffron. Khumbauk sends to Tibet, horses, dromedaries, and Balgar hides. In Tibet there are several mines of lead; and as lead-ore contains silver, it might be separated from it to great advantage, if the method of doing it were known. Here are also mines of cinnabar, which contains a great proportion of mercury, if the Tibetians knew how to extract it. The copper-mines furnish materials for the manufacture of idols, and all the ornaments disposed about monasteries, on which gilding is bestowed, for which there is a great demand in Tibet.

A very small quantity of specie is current in Tibet, and that is of a base standard. It is the silver coin of Nipal, here denominated *indermillee*, and worth about one-third of a sicca rupee; and it is cut into halves, third parts, and quarters. In all mercantile transactions, however, the equivalent is made in bullion, *i. e.* talents of gold and silver, valued in proportion to the purity and specific gravity of the metal.

The commerce between Tibet and China is carried on principally at a garrison town, on the western frontier of China, named Sining, or Silling: thither merchants resort from Tibet with their manufacture; *viz.* a thin cloth resembling frieze, but rather of a more open texture, gold-dust, and some other commodities procured from Bengal; which they exchange for tea, silver bullion, brocades, and fruit. In these articles an extensive trade is carried on; and Mr. Turner has been assured that, on the territory of Teshoo-Loomboo-alone, tea, to the amount of five or six lacs of rupees, is annually consumed. From hence, too, Bootan is supplied with tea, which is in the same general use there.

Tibet exports to China, gold-dust, diamonds, pearls, coral, musk, woollen cloths of its own manufacture, lamb-skins and otter-skins, called *ood*, brought from Bengal; and China returns to Tibet, gold and silver brocades, plain silks, satins, black teas of four or five different sorts, tobacco, silver bullion, quicksilver, cinnabar, china ware, trumpets, cymbals, and other musical instruments; furs, *viz.* sable, ermine, black fox; and dried fruits of various sorts.

The regulations for carrying the commerce of the English East India Company through the dominions of Bootan, by means of the agency of native merchants, were settled by the treaty entered into by Mr. Bogle, in the year 1775.

The cities and towns of Tibet are little known: the capital is *Lassa*; which see. Among the edifices, the monasteries occupy the first class. (See TESHOO-LOOMBOO.) The chief river of Tibet is *Berhampooter*; which see. The Hoan-ho and Kian-ku of the Chinese also derive their origin from the eastern boundaries of Tibet. The great Japanese river of Cambodia, or Maykaung of Laos, that of Nou Kia, supposed to pass near Martaban, into the gulf of Pegu, and the Irawaddy of the east country, are supposed to have their sources from the mountains of Tibet, which may be styled the Alps of Asia. Another large river, called the Sardjoo or Gagra, which, after a course of about 600 miles, nearly parallel on the E. with that of the Ganges, joins it near Chupra, and derives its spring from the lofty western mountains of Tibet. In these Alpine regions are many lakes, such as *Terkiri*, and *Jamdro* or *Pelté*; which see. The ranges of Tibetan mountains in the W. and S. seem to bend in the form of a crescent, from the sources of the Ganges to the frontiers of Afam, in a N.W. and S.E. direc-

tion. To the N. of Sampoo a parallel and higher ridge seems to extend, the northern extremities abounding with large frozen lakes. The chief elevation of mountains appears to be central, S. of the lake *Terkiri*, and is called *Koiron*, the western part being denominated *Kantel*. The southern range presents many names of distinct mountains, comprehended under the Hindoo name of *Himmela*. From these ranges many branches extend N. and S. This country possesses many mineral waters, the salutary use of which is not unknown to the natives. Among its natural curiosities we may reckon a singular rock, N. of *Tassifudon*, described by Mr. Saunders in the Appendix to Turner's Travels, and forming in front six or seven angular semi-pillars of large circumference, and some one hundred feet in height. This natural curiosity is partly detached from the mountains, and projects over a considerable fall of water, which heightens the picturesque appearance of the whole. The rock is laminated, and might be formed into slate; and as iron-stones are found in the vicinity, these pillars probably, like those of basalt, arise from the influence of that metal. Phil. Trans. vol. lxxvii. Sir W. Jones's Works, vol. iii. Turner's Travels. Pinkerton's Geography.

TIBET or TIBET, *Little*, a district N.W. of Cashmere, which is supposed to contain the chief source of the Indus. The situation of this country is doubtful; it probably lies on the N. and N.W. of Cashmere, and is divided from Great Tibet by a high mountainous ridge, and by a higher chain, that of *Belur*, from Great Bucharia. It is described as a very mountainous and poor country, pervaded by the Indus, and towards the N. full of forests. The capital is *Afcardu*, and further to the N. is *Schekar*. *Temir-kand*, or the fortrefs of iron, seems to command the pass between Great and Little Tibet; and the two Ganges of the Chinese maps (supposed sources of the Ganges) are probably rivers which join the Indus from the East. Pinkerton.

The delineation of the country of the *Sææ*, by Ptolemy and Strabo, (see *SACÆ*.) will be found to correspond, says Hugh Murray, esq. in his "Ancient Geography of Central and Eastern Asia," in every respect, with that given by Mr. Elphinstone of the Plain of Pamera and Little Thibet. It was bounded on the S. by Hindooftan, from which it was separated by the ridge of Imaus. On the N. it was bounded by the next parallel chain, "*Mons Ascataneas*," which cannot possibly be any other than the *Mooz-Taugh*, to whose name, indeed, it bears a rude resemblance. It extended E. from the *Montes Comedorun*, (the *Beloor* or *Belur*.) to somewhat beyond the head of the Ganges; precisely the dimensions of Little Thibet. Great and Little Thibet form a table land of extraordinary elevation, bordering on Hindooftan to the S.; and two parallel chains, running from E. to W., prop this mighty bulwark of Asia. The northern barrier is formed by an immense chain, known under the name of *Hindoo Coosh*, and *Himmela* or *Himalaya*, which forms the northern limit of India. The whole extent of it is covered, to a great depth, with perpetual snow; and every measurement yet made, from *Peshaur* to *Nepaul*, has made it exceed 20,000 feet above the level of the plain, being higher than the highest peaks of the Andes. The whole is recognized by Ptolemy under the name of *Imaus*. The northern range, known by the uncouth appellation of *Mooz-Taugh*, *taugh* being merely the generic name of mountain, or *Karrakorum*, Mr. H. Murray apprehends to be described by him under the name of *Mons Ascataneas*. Its absolute elevation seems to exceed that of *Himalaya*, and yet from the high level of its base, it does not present so formidable an aspect. At right angles

angles to both, connecting them, and shutting in the western side of the table land, is another chain, called the Beloor-Taugh; forming the eastern limit of Shognaun, the ancient Sogdiana, and thus coinciding with the Montes Comedorun. According to the writer now cited, the "Scythia extra Imaum" of Ptolemy must be Great Thibet, with an extent of Tartary stretching indefinitely northwards. After Scythia, he says, comes the famous Serica; and if Great Thibet be Scythia extra Imaum, the next great country must be China, which he concludes from a variety of circumstances to be Serica. This writer thinks Pinkerton's hypothesis, mentioned under SERICA, of its being Little Bucharia, altogether inadmissible. See Murray's Ancient Geography of Central and Eastern Asia.

THICKET, a close knot or tuft of trees; a close wood, &c. in any field or inclosure of any kind.

THICKETS, in *Gardening*, a sort of close plantations of trees and shrubs, in pleasure-grounds, parks, &c. They are designed for different purposes, as sometimes to repel the force of tempestuous and cold cutting winds, either from the habitation, or some particular part of the garden; or to form places of shade and retirement in summer, having spaces for walks, recesses, &c. under the umbrage of the trees, and occasionally to conceal from view any unsightly or disagreeable object, and also sometimes to form a screen or blind arranged towards some outward boundary.

They are sometimes planted wholly of the large tree kinds, five or six to eight or ten feet asunder, some in regular lines, like a close grove, or more generally in a sort of promiscuous planting, but with some degree of order in the distances: they are also often composed of various trees and shrubs together, to effect a more full, close growth below and above, and to display a greater diversity in the plantation, by disposing the various shrubs properly between the larger trees, in some order of gradation, the lowest towards the front, and the taller growths backward, so as to form a sort of close underwood thicket below, while the trees run up and form a thicketty growth above; and sometimes they are formed wholly of shrubs of different sorts and degrees of growth, from the lowest placed forward, to the tallest behind.

They are sometimes, too, formed wholly of particular sorts of trees disposed separately in distinct plantations, as of elm, ash, beech, poplar, alder, willow, &c.

The planting of thicket plantations should be effected with young trees of from four, five, or six, to eight or ten feet growth, and the shrub kinds proportionally; in all of which the planting may be performed in the common seasons of autumn, winter, and spring.

In the culture of thicket plantations, little is required but that of keeping them clear from large overbearing weeds, while the trees and shrubs are in young small growth.

Thickets are now much less in use than was formerly the case in ornamental gardening, and pleasure-ground planting; they may, however, on some occasions, be introduced with good effect.

THICKON, in *Geography*, a river of Pennsylvania, which runs into the Delaware, N. lat. $40^{\circ} 25'$. W. long. $75^{\circ} 8'$.

THICKSTUFF, a name for sided timber exceeding four inches in thickness, but not being more than twelve inches in thickness.

THIEBLEMONT, in *Geography*, a town of France, in the department of the Marne; 8 miles E.S.E. of Vitry le Français.

THIEL, or **TIEL**, a city or town of Holland, in the department of Guelderland, situated on the north side of the Wahal, in a small island called *Tieler-Waert*. In one of its fauxbourgs, called *Santwyck*, which is well fortified, is a

strong citadel: the fortifications were destroyed in the year 1674, by the French, who had made themselves masters of the place about two years before, and have been since repaired. In the year 1528, it was besieged by the Spaniards, when Charles V. was at war with the duke of Gueldres; but they were compelled to raise the siege, through the brave resistance of the citizens. The country about it is marshy, and the air reckoned unwholesome. The fortifications are destroyed; 18 miles N.N.E. of Bois-le-Duc.

THIELLE, a town of the county of Neufchâtel, between the lake of Bienne and the lake of Neufchâtel; 5 miles N.E. of Neufchâtel.—Also, a river of Switzerland, which rises in the Vaudois, passes through the lakes of Neufchâtel and Bienne, and runs into the Aar, 3 miles below Buren.

THIELLEN, a town of Switzerland, in the canton of Uri; 2 miles N.W. of Altorff.

THIELT, a town of France, in the department of the Lys; 10 miles N. of Courtray.

THIENE, a town of Italy, in the Vicentin; 9 miles N.W. of Vicenza.

THIERS, JOHN BAPTIST, in *Biography*, a divine, was born at Chartres about the year 1636, and became a bachelor of the Sorbonne, professor in the college of Du Pleffis at Paris, and curé of Chauprend, in the diocese of Chartres. Being arrested in consequence of a dispute with the clergy of Chartres, and a satire against one of them, he escaped by a stratagem, and found refuge with the bishop of Mans, who gave him the cure of Vibraie, where he died in February, 1703. His works are numerous, freely written, and on singular subjects; but we refer for an account of them to Moreri, the Nouv. Dict. Histor. and Gen. Biog.

THIERS, in *Geography*, a town of France, and principal place of a district, in the department of the Puy-de-Dôme; here are manufactures of cutlery, playing-cards, paper, thread, &c.; 21 miles S.E. of Gannat. N. lat. $45^{\circ} 52'$. E. long. $3^{\circ} 38'$.

THIERSHEIM, a town of Germany, in the principality of Culmbach; 6 miles N.E. of Wonfriedel.

THIERSTEIN, a town of Germany, in the principality of Culmbach, on the Eger; 5 miles N.E. of Wonfriedel.

THIE-WEY-ARA-YETH LAKE, a lake of North America. N. lat. $61^{\circ} 20'$. W. long. $106^{\circ} 30'$.

THIGH, **FEMUR**, a part of the body of men, quadrupeds, and birds, between the leg and the trunk. See **EXTREMITIES**.

We have an account in the Philosophical Transactions of a large piece of a young man's thigh-bone being taken out, and the place so well supplied by a callus, that he walked straight. See N^o 461. sect. 2.

THIGH-Bone, *Fractured*. See **FRACTURE**.

THIGH, *Luxation of*. See **LUXATION**.

THIGH, in the *Manege*. The effect of the horseman's thigh is one of the aids that serves to make a horse work vigorously. See **AID**.

Fore-thigh, or arm of a horse, is that part of the fore-leg that runs between the shoulder and the knee: though the fore-thigh does not bend or bow, yet we commonly say, a horse goes fine, that bends well the fore-thigh, importing by it, that he bends well his leg.

Horses should always be full and well made in the thick parts of the thigh, especially in horses of the working kinds.

THIGHT, in *Agriculture*, a term provincially applied to turnip, or other crops which are thick or closely set. It also signifies impervious, when applied to roofs or vessels in some districts.

THILACHIUM, in *Botany*, so named by Linnæus, from

from *Thaxos*, a little bag, alluding to the form of the calyx. It ought rather therefore to have been *Thylachium*.—Loureir. Cochinch. 342.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Capparides*, Juss.

Gen. Ch. *Cal.* Perianth inferior, oblong-turbinate, ribbed, pointed, undivided, close, at length bursting all round. *Cor.* none. *Stam.* Filaments numerous, about seventy, awl-shaped, long, erect, inserted into the receptacle; anthers oblong, upright. *Pist.* Germen superior, on a stalk the length of the filaments, oblong, striated; style none; stigma roundish. *Peric.* Berry oblong, with ten sides, of one cell. *Seeds* numerous, kidney-shaped, imbedded in pulp.

Ess. Ch. Calyx of one leaf, oblong, bursting all round. Corolla none. Berry stalked, with ten angles, one cell, and many seeds.

1. *Th. africanum*. African Pouch-flower.—Observed by Loureiro on the eastern coast of Africa, near Mozambique, where it is called by the Portuguese *Manguero*. The tree is small, with spreading branches. Leaves alternate, stalked, ovate, entire, smooth. Stalks terminal, bearing several flowers, whose long stamens are of a saffron colour. The author observes that this genus approaches *Capparis*, in its stamens and the stalk of its berry, but differs widely in the unusual form of the calyx, as well as the want of a corolla, and the figure of the seed-vessel. De Theis thinks it allied to *MARGRAVIA*, see that article. As far as it is related to *Capparis*, he is right; but between the corolla of *Margravia*, and the calyx of *Thilachium*, which he seems to have had in view, there can be no affinity; any more than between the latter and the pouch in the outer calyx of *RUYSCHIA*, which article the reader may likewise consult. We must be content to leave the matter as we find it, there being great probability, considering how little we know of the botany of its native country, that the plant, and even its genus, are entirely new to Europeans.

THILAY, in *Geography*, a town of France, in the department of the Ardennes; 7 miles N.N.E. of Charleville.

THILCHATEL, a town of France, in the department of the Cote d'Or; 14 miles N. of Dijon.

THILCO, or rather **T'HILCO**, in *Botany*. See **FUSCHIA**, n. 9.

THILL, in *Rural Economy*, the name of the framed shafts of carts and waggons, between which the horse draws and moves. The thills of these kinds of carriages should always, as much as possible, be made of tough ash-wood, and light in proportion to the nature and uses of them.

THILL-HORSE, the last horse in a team, or the horse that goes between the thills or shafts; which often sustains much undue weight and pressure on the back, in consequence of the load which is drawn. This is capable of being relieved in various ways and by different contrivances, but the two which are noticed below would seem to be the most simple and easy. It is well known to be almost universally the practice to hook or attach the second horses, in cart or waggon teams, on at the end of the shafts. The consequence of which is obviously this: whenever the cart or carriage ascends a hill, and the fore part of the team comes to level ground, which not unfrequently happens, while the thill-horse or horses are still on the declivity, from their force being exerted in a right line to the ends of the shafts, all the powers of the whole of the leading horses must, in such cases, inevitably load and oppress the thill-horse or horses, when so directed, as they tend to depress the shafts, in their exertion to draw at the proper point of draught; that is, in the line with the axle. The thill-horse or horses are often seen, in such instances, nearly borne

down, where the ascents are steep, and the levels rather suddenly regained. The back, or backs, of such horses become a sort of fulcrum, on which the strength of all the preceding horses acts as a kind of lever; which, if sufficiently forcible, and the thill-horse or horses' backs were strong enough to bear the pressure, must lift the carriage off the ground, until it should come to a level with the line of their pull.

In order to remedy this great pressure and inconvenience, it is advised that a looped iron, of about a foot in depth, in the whole, be fastened to the end of the shaft; nailing and rivetting it firmly, by means of expanded flats. The looped part will then reach about eight or nine inches under or below the shafts. Each trace is to be carried through these loops instead of hooking on there, and be fastened at the bottom of the shaft, near to where it hitches on to the frame of the carriage. This will give play to the traces, and wholly relieve the thill-horse or horses from the undue pressure to which they are exposed.

The principle here laid down is necessary, whatever other method may be had recourse to in removing the inconvenience.

At Hinton-House, in Berkshire, S. Nicolls, esq. is said to effect this in a somewhat different manner, the aim of which is the prevention of the draught of the trace-horses pulling down the thill-horse or thiller, which is always found to be the case, when they draw from a *drail*, as it is termed, in the fore part of the shaft, if the thill-horse be taller than the trace-horses, or if the latter are going down a declivity, before the former has passed its summit, as seen above.

The preventive practice or mode in this case is by inserting a chain to the hinder part of the shafts, which is also attached, and confined in some measure, to the fore part of the shaft (where the drail is generally placed) by a piece of chain, which allows it to move freely to a certain distance from the shaft, in order that the draught may be constantly kept in a horizontal direction.

THILYPTERIS, in *Botany*, a term used by Dillenius to express the common female fern or brakes.

THIMA, in *Geography*. See **TIMA**.

THIMBLE, a cover for the finger, made of brass, steel, or silver, and used by all people who sew, as tailors, milliners, &c.

THIMBLE, in *Sea Language*, an iron ring with a groove round the outside, to receive the rope it is spliced into. Thimbles are spliced into the rigging and fails for blocks to be hooked to, or ropes to reeve through where blocks would appear too heavy.

THIMBLE ISLANDS, in *Geography*, small islands near the coast of Connecticut. N. lat. 41° 11'. W. long. 72° 42'.

THIMBRIC-KEUY, a village of Asiatic Turkey, in the province of Natolia, on the site of an ancient town called "Thymbra," built by Dardanus, king of Phrygia. Here are some considerable ruins, supposed of a temple of Apollo.

THIMDA, a town of Tunis; 8 miles S.W. of Bizerta.

THIMIO, in the *Materia Medica*, a name used by some authors for a peculiar sort of lignum aloes, which is blackish and very heavy, and extremely sweet.

THIN, a name given by the Arabian writers to earth of any kind.

Thus the bole armenic of Galen is called by Avicenna *thin Armeni*; and hence the word *mutbin*, an adjective signifying earthy, or approaching to the nature of earth; a term applied to many medicines of this kind.

THINA, in *Botany*, a name by which some authors have called the *larix*, or larch-tree.

THINGAU, in *Geography*. See TINGÆ.

THINGVALLA, a place of Iceland, about 26 miles distant from Reikiavik, and 24 miles from Skalholt; in which is a small, mean, and dirty church. The scenery about it is romantic; but the want of wood, and the effects of subterraneous heat, combine to give it a dreary aspect. The adjoining lake of the same name is a fine sheet of water, reckoned to be about ten miles long and from three to seven in breadth. In the lakes are two pretty large islands, called Sanday and Nefey, composed entirely of volcanic matter. The depth of the lake is said to be very great; a line of 100 fathoms having been sunk without reaching the bottom. It receives the waters of the surrounding bogs, and near it in different places vapours are seen to ascend from hot springs. It abounds with trout. At the S. end the mountains are very picturesque, and the ascending vapours contribute to the solemnity of the whole scene, as they arise from springs that have been produced by the most dreadful commotions, and the destruction of a country that may once have been beautiful and fertile. Near Thingvalla is a building, where the courts of justice were formerly held; but as Reikiavik is now the seat of government, the courts are held there. It does not appear why this place was originally selected for the seat of justice; but a town being once established, and trade carried on freely, and to a greater extent than in former times, ready recourse to the law became necessary. Although not more than fifteen years have elapsed (1817) since the judicial courts were transferred to Reikiavik, few remains are left to mark a spot so famous in the history of Iceland. The only building is a small wooden house, in which the consultations were held and sentence pronounced by the stiftantment or governor. The magistrates and people assembled on the occasion lived in tents. The culprits who were condemned to die were beheaded on a small island in the river Oxeran, which here flows into the lake. The females were drowned in a deep pool below the lava, a little farther up the valley. An ecclesiastical court used to be held at Thingvalla by the bishop of Skalholt, attended by the provosts and two ministers from each Syffel. It is suggested, that Tingwall in Shetland, and Dingwall in Ross-shire, are evidently the same names as Thingvalla; and were probably, in ancient times, places where justice was administered. Towards the N. are several ranges of mountains, which, from the account received, and the appearances observed, are volcanic. Among these, the principal seems to be Skalbreidé, a lofty Jokul, of which description of mountains others were seen at a distance. Although the transference of the superior court from Thingvalla to Reikiavik has, probably, been attended with advantage, the Icelanders, as a people, have some reasons for regarding this change with regret. The annual meeting at Thingvalla was not merely that of a tribunal of justice, but an assembly of the nation; and though the importance of this assembly was diminished, and its dignity degraded, by the subjection of the island to a foreign power, yet on the spot where the greatest among his ancestors so often stood, the mind of the Icclander must ever have been awake to enthusiasm and patriotic pride. "Hic sacra, hic genus, hic majorum multa vestigia!" Mackenzie's Iceland.

THINKING, COGITATION, a general name for any act or operation of the mind.

Chauvin, with the Cartesians, will have thinking to consist in a certain native, inherent motion or agitation of the human mind, of which itself is conscious.—*Native* and *inherent*, since he conceives it no other than the very essence of the mind itself, or, at least, its principal and fundamental property: an *agitation*, since there is a new modification or

change made in the mind, which we scarcely know how to conceive without motion; add, that the origin and etymology of the word *cogitation*, according to Varro and Festus, implies as much; *cogito* being used for *coagito*.

When the mind turns its view inwards, upon itself, the first idea that offers, says Mr. Locke, is thinking; in which it observes a great variety of modifications, and of them frames to itself distinct ideas: thus the perception annexed to any impression on the body, made by an external object, is called *sensation*.

When an idea recurs without the presence of the object, it is called *remembrance*.

When sought after by the mind, and brought again into view, it is called *recollection*.

When held there long under attentive consideration, it is called *contemplation*.

When ideas float in the mind without regard or reflection, it is called a *revery*; when they are taken express notice of, and, as it were, registered in the memory, it is *attention*; and when the mind fixes its view on any one idea, and considers it on all sides, it is *study* and *attention*.

These are the most obvious modes of thinking; but there are several others which we know of; and, doubtless, the mind is capable of infinite others, of which we have no notion at all.

The school-philosophers usually divide thinking, with regard to the object it is employed about, into understanding, *intellectio*; and willing, *volitio*.

And hence, those are said to be the two powers or faculties of the human mind.

Intellectual thinking is farther subdivided into divers kinds; the first, when the mind merely apprehends or takes notice of a thing, called *perception*; the second, when it affirms or denies a thing, called *judgment*; the third, when it gathers or infers a thing from others given, called *reasoning*; the fourth, when the mind disposes its own thoughts or ideas in order, called *method*.

Volitive thinking, or volition, admits of infinite different modifications, or new determinations.

Some authors extend the idea of thinking farther; and consider it in God, angels, brutes, &c. whence results a new division of thinking, into divine, angelical, human, and animal or sensitive.

But the two first we know little or nothing of: the third is that of which we have already been treating.—As to the last, *viz.* animal or sensitive thought, it is defined to be, an action of the soul attending to an external object, affected by means of the animal spirits duly agitated in the brain, to excite an idea.

The Cartesians maintain, that thinking is essential to the human soul; and, consequently, that there is no time when the soul does not think: but this doctrine has been very vigorously attacked by Mr. Locke; who labours to shew, that in sleep, without dreaming, there is an entire cessation of the modes of thinking.

I think, cogito, according to Des Cartes, is the first, and most certain, of all truths; from which, alone, we draw this consequence, *therefore I am*, or exist, *sum*.—One might also say, *cogito, ergo Deus est; I think, therefore there is a God*.—Logic is defined, the art of thinking methodically.

THINNING of *Plantations and Woods*, in *Agriculture*. The practice of thinning plantations of trees and woods, so as to let the plants of them have more room as they advance in growth, is mostly an operation of considerable importance; as upon it, perhaps, more than upon any other point of the after-management in such cases, depends the nature, quantity,

tity, and modification of the timber which is raised and produced.

Woods of the natural kinds, the seeds of which are sown by birds or the winds on soils and surfaces of very different descriptions and sorts, rise and spring up at different times, and of very different degrees of thickness, strength, and vigour in themselves and their different parts; consequently it is easy to suppose, that those which are placed in favourable situations and circumstances, will quickly overtop the others; and if they do not wholly destroy, will at least weaken them in such a way as not to be affected or inconvenienced by them, until the strongest trees ultimately find ample and sufficient room for their growth. In this way, although nature may be slow in her operations, she effects her purpose in a very complete manner. Besides these observations, Mr. Loudon has noticed that artificial thinning is only assisting nature; and that hence even leaving natural woods to be thinned by time, would not be economical.

It is suggested with regard to artificial plantations, that in these the soil is equally cultivated, and the plants are put into the ground much about the same size, and at the same time, and that hence they of course rush up together all nearly of the same height, producing neither ornament nor timber; and none being produced so strong as to take the lead and destroy the rest, they grow in this manner until they are so crowded as to exclude air and moisture. At which period, unless assistance has been previously given by thinning, the whole of the plantation dies together, and is destroyed.

Where thinning is necessary in old natural woods, or such as have been planted, it should constantly be performed by degrees in a regular manner, well considering the state, qualities, and habits of the trees, as well as the nature of the soil on which they grow, the situation and exposure in which they are placed, and other similar matters. The outsidings of them should commonly be less thinned than the other parts, and the trees on the richer parts of the land be more thinned than those on the other descriptions of it. The thinning of the side shoots and branches of the trees should likewise, in some measure, accompany the other thinning, and be performed in a suitable manner to their natures, states, and purposes for which they are intended.

It is, however, mostly the custom to begin to thin them out at about seven years from the time of planting them, or that of their first growing up, and to repeat it every seven years afterwards. When the planting has been performed in the proportion of from six to eight hundred trees to the acre, they may be made to stand, in the first thinning, at about one tree to each rod of ground, or nine trees to eight rods. But in the second thinning, a rather larger proportion of trees should be taken out, as rather more than one to each rod; and in the third thinning, the proportion may be made still in a larger ratio, so as to leave the trees about a rod square each. Much must, however, always depend upon the nature, situation, and circumstances of the particular plantations and woods.

In all these thinnings the worst trees should be removed, so as to leave the straightest and best plants to stand for timber or other purposes.

It is suggested, that as in most plantations the fir tribe of trees has been introduced either for the purpose of ornament or shelter; where thinning is practised, in such cases, too large a proportion of these firs are mostly left. Hence, from their comparatively quick growth, it is concluded that such plantations have a disagreeable sameness through-

out; and that, as most of them are made in the same manner, this appearance extends itself over the whole country.

The plantations in which thinnings in the way of ornament is most particularly required, are those which are designed for groves. In many woods and copses no plants require to be taken out but the nurse ones, where any such have been planted. Plantations of the fir kind, Mr. Loudon advises to be thinned somewhat gradually, beginning the work after they have been five or six years planted, and continuing it for ten or twelve years: after which time, thinning, he thinks, becomes pernicious. And that the trees which are to be thinned out should constantly be grubbed up by the roots; for that when these are suffered to remain, they check the progress of the trees which are left. But these sorts of plantations are sometimes, and very properly, left altogether without thinning, being cut down wholly as a crop when fifteen or twenty years old, or of about that standing. This is conceived to be in general the most profitable mode of planting and after-management on thin, bare soils in the vicinity of mines and pits, where wood of this sort is greatly in demand by the proprietors for the support of the upper strata. Where some of the fir tribe have been planted as nurseries, they are recommended to be thinned out in a gradual manner, by being grubbed up as they begin to injure and inconvenience the principal trees. And groves, where the trees are of the deciduous kinds, should be thinned out after the same manner; only, the work in these cases may proceed until the trees have arrived at nearly their full growths.

Woods, where under-growth is always the object intended when they are properly planted, require, as has been seen above, no sort of thinning, unless in cases where nurseries have been planted, or when the timber-trees are too much crowded by the low growths; the whole should be suffered to grow for twelve, fourteen, or more years, or until the under-growth is in a suitable state to be cut over; when at that period the strongest trees should be fixed upon, and left as standards in a properly thin state. As copse-woods usually grow a certain length of time in proportion to their natures and kinds, and are then wholly cut over by the surface of the ground; they, of course, demand less thinning than others, or none at all, except when nurseries have been planted among them; and in the case of both woods and copses, these, as they are thinned out, should constantly be replaced by the principal trees at suitable distances.

In all cases where ornament is in any way considered, the above writer thinks the trees or copse left in thinning should not be equidistant from each other, but in groups of irregular thickness; and it is supposed that the same may be had recourse to even in woods where utility is the chief consideration; as it will make no material difference in the produce of timber, and is so much more natural. See PLANTATION and PLANTING. See also TIMBER and WOOD.

THINNING out Crops, the practice of thinning out such plants among them as are too thickly or closely placed together, as in the case of turnips or other similar crops. In the different sorts of turnips, the thinnings may be made in such a manner as that the plants may stand ultimately at the distance of from seven or eight to nine or ten inches every way from each other, in proportion as the land is more poor or rich in its quality. But in carrot crops, the thinning them out to the distance of about eight or twelve inches, according to the richness of the soil, may probably be the most proper practice. And the same will mostly be the case for those of the parsnip and beet kinds.

Where cabbage, borecole, or other similar crops, are sown,

sown, they should always be thinned out to the distance of a foot and a half, two feet or more, as the soil may be of a less or more rich quality. And lettuces, when put in by sowing, should be thinned to the distance of from eight to twelve inches, according to the nature of the soil.

The thinning out of any other sorts of field-crops of these kinds must also be performed according to their natures and particular habits of growth.

Some of these sorts of crops are best thinned out in a gradual manner, as the turnip, carrot, beet, &c.; while in others it may be done all at once, as for the cabbage, and some other kinds.

There are several different methods practised in accomplishing this business, as by means of the hand simply, the use of the hand-hoe of different suitable sizes, according to the states and circumstances of the crops, and lately in the row kinds, by an implement invented for the purpose. This last is by much the cheapest and most expeditious manner of performing the work; if it should be found, on further trial, to be equally accurate and effectual in the execution of the business. This sort of tool or machinery was invented and constructed on the farm of Charles Gibson, esq. at Quarmer Park, near Lancaster, and a representation of it is given in the Corrected Agricultural Survey of that county, lately published. See *THINNING and Hoeing Machine for Turnips, &c.*

The other modes of effecting and completing this kind of work, are a great deal more troublesome, laborious, and expensive than the above, especially the first of them, as many hands and much time are required for doing it in the most proper and effectual manner by such means. Where the hand-hoe is employed, two or three different sized hoes are mostly made use of for the purpose in the different successive thinning hoeings, which, when in the hands of experienced workmen, do the business in a pretty quick, easy, and complete manner, as the supernumerary plants are struck and cut out with much exactness and regularity. It is constantly necessary in such cases to keep the hoes in a pretty sharp state, in order to perform the work well, and with neatness. The principal objections to doing this sort of labour by the hand, are its tediousness, and the treading which takes place during the operation.

THINNING out Plants, in Gardening, the pulling or drawing out such as are too close and thick in some crops of the general and other kinds, as well as in some other cases, so as that the remaining ones may stand at proper and suitable distances for producing the most favourable crops, plants, or other productions. This is mostly practised in the cases of the main crops of onion, carrots, parsnips, beets, spinach, and several other similar kinds, which are sown in the broadcast manner; in different small seed crops, for raising plants to be afterwards set out, such, for instance, as the cauliflower, brocoli, cabbage, borecole, lettuce, endive, and many others; and in the producing and bringing forward young tree plants of most sorts in nursery grounds and other places.

Onion crops are, for the most part, thinned out at different times, as the demands of the markets, or in other ways may be, so as to leave the remaining plants at the distances of four or five inches or more from each other, according to their nature, kinds, and other circumstances; always, however, allowing sufficient room for their full and complete growths. Much advantage is often made in this way by the young onions which are thinned out, which would otherwise be lost and thrown away.

The carrot, parsnip, and beet crops are commonly thinned

out at one or two thinnings, the standing plants being left at the distances of about six or eight inches apart, as the nature of the soil and crops may be. The young plants of the carrot kind, thus drawn, are in some cases bunched and made use of, especially when the crops are late in being thinned out, which should always be avoided as much as possible.

Lettuce and spinach crops may be thinned out at once to the distances of six, eight, or more inches between the plants, in the different kinds, as the nature of them may be, when put in upon the broadcast plan. The thinnings are of little use or value, except for waste purposes, such as being thrown to the hogs, &c. in these instances. Most other similar sorts of crops may be thinned out in the same manner.

The small seed crops of the different kinds should constantly be kept so thinned out as to prevent the plants of them from being drawn up in a weak manner, and unfit for being set out; as where the contrary is the case, there is always great waste, and the plants seldom succeed so well. They should be gradually thinned out by planting, as well as in other ways.

Young tree plants, in most cases, require frequently thinning out in their early growths, in order to raise and bring them forward in the best and most perfect manner. They should therefore, in general, be so kept thinned out as never to want sufficient room for rising in the manner which is the most natural and proper for them, and for preventing the injury they may sustain by standing too close in the rows or otherways.

Due, early, and proper thinning out of crops and plants, is of course a matter of considerable importance and utility in the garden culture of different sorts of vegetables, trees, and other productions of the same kinds.

THINNING and Hoeing Machine for Turnips, that sort of implement or machine which is contrived for the purpose of thinning or setting out this as well as other similar kinds of crops that stand in rows. It is made light, and constructed somewhat in the form of the plough, having a suitable apparatus so attached to it behind as to be put in motion, and strike out the supernumerary plants as the horse proceeds regularly along the intervals of the ridges. The horse is driven by the person who holds and directs the tool while at work. It is capable of going over a very considerable space of ground in a short time, and if found, on the result of further trials, to perform the work with due accuracy and correctness, will be a very great acquisition to the drill turnip husbandry, and for different other purposes of the same nature.

THIONVILLE, in *Geography*, a town of France, and principal place of a district, in the department of the Moselle. The place contains 5014, and the canton 13,988 inhabitants, on a territory of 175 kilometres, in 27 communes; formerly belonging to the duchy of Luxemburg, and ceded to France by the treaty of the Pyrenées in 1659. N. lat. 49° 21'. E. long. 6° 15'.

THIORSAA, a large turbid river of Iceland, on the road from Skalholt to mount Hetla, the course of which is nearly from N.E. to S.W. In its passage over rugged masses of lava rising abruptly from its bed, this river dashes among the rocks, and forms impetuous rapids and falls.

THIR, in *Chronology*, the name of the fifth month of the Ethiopians, which corresponds, according to Ludolf, to the month of January.

THIRD, TERTIUS. See **NUMBER** and **NUMERATION**.

THIRD, in *Music*. The 3d is the most agreeable and necessary

necessary concord in counterpoint, throughout the whole system of practical harmony.

There are two kinds of thirds; the major or sharp 3d, which is four semitones or half notes above the base; and the minor or flat 3d, which is three.

Very agreeable music in two parts may be composed, and often is composed, of thirds only. The 3d is wanted with every other concord, and even discord, except the 4th, when it is used as such with the 2d instead of the 9th.

Dr. Pepusch, in his "Treatise on Harmony," has given curious and ample instructions for the use of thirds in composition.

It would be a curious inquiry, why a 3d was regarded by the ancients as a *discord*; and why it is called by the moderns an *imperfect concord*. We cannot afford space for long disquisitions on every subject of vain and frivolous curiosity, among which this would probably be numbered. But it seems as if the ancients estimated the perfection of consonances by the simplicity of ratios in the division of the monochord; regarding the *octave* as the most perfect concord next to the unison, as it was produced by a simple division of a string into halves, expressed by

The next in perfection was the 5th, produced by a third part of a string	$\frac{1}{2}$
After this, the 4th, which was reckoned by the ancients not only a concord, but a <i>perfect concord</i> , expressed by the ratio of	$\frac{3}{2}$
A fourth part of a string gives the 15th, or double octave	$\frac{3}{4}$
The fifth part of a string produces the major 3d to the 15th, which, though in the organ the stop called the <i>tierce</i> , it is a major 17th to the diapason: its ratio is expressed by	$\frac{2}{3}$
The minor 3d is expressed by	$\frac{5}{6}$
The major 6th, composed of four tones and a semitone major, as $\frac{E}{G}$: its ratio is	$\frac{3}{5}$
The minor 6th, composed of three tones and two major semitones, as $\frac{C}{E}$: its ratio is	$\frac{4}{5}$
The extreme sharp, or, as the French call it, the superfluous 6th, composed of four tones, a semitone major, and a semitone minor, as $\frac{G^{\sharp}}{Bb}$: the ratio of this 6th is	$\frac{7}{12}$

We believe that the triple progression of a series of perfect 5ths made the major 3ds so extremely harsh, that no natural good ear could admit them among the concords. And in the first attempts at counterpoint, it was a long time before a 3d was admitted in *discant*; in which *diatessaronare* and *quintoier*, or a diatonic series of 4ths and 5ths, now prohibited, was preferred to 3ds and 6ths in succession.

THIRD Borough, in our *Ancient Law-Books*, denotes a constable.

THIRD Earing, in *Husbandry*, the tilling or ploughing of the ground a *third* time.

THIRD Estate. See **ESTATE, COMMONS, &c.**

THIRD Night-awnd-hynd. By the laws of Edward the Confessor, a guest, who had lain three nights in an inn, was reputed a domestic, and his host was answerable for what offence he should commit.

For one night he was accounted *uncuth*; for two nights, *guest*; and the *third, awnd-hynd, or hogen-hyne*. "Prima nocte incognitus, secunda hospes, tertia domesticus censetur."

THIRD Order, a sort of religious order, that observes the

same rule, and the same manner of life, in proportion as some other two orders instituted before.

The third orders are not originally religious orders, but associations of secular, and even married persons, who conform, as far as their condition will allow them, to the design, intention, and rules of a religious order, which associates and directs them.

The Præmonstrantes, Carmelites, Augustines, and Franciscans, dispute among themselves the honour of having first introduced third orders; but the pretensions of the last appear to be the best founded.

The first contend, that the third order of Præmonstrantes began in the life-time of their founder St. Norbert, who died in 1134.

F. Diego de Coria Maldonado, a Spanish Carmelite, who has a particular treatise on the third order of Carmelites, derives them immediately, as well as the Carmelites themselves, from the prophet Elijah.

The third order of Augustines, if we credit F. Bruno, was instituted by St. Augustine himself; but the arguments he produces are so frivolous, that F. Helyot observes, they are not worth refuting.

The third order of Franciscans was instituted by St. Francis in 1221, in favour of people of both sexes; who being smitten with the preachings of that saint, demanded of him an easy manner of living a Christian life; upon which he gave them a rule, the constitutions of which are not now extant, as written by himself, but only as reduced and confirmed by pope Nicholas IV. sixty-eight years afterwards.

Those of the first order of this saint are the monks called *Minor Friars*, comprehending the Cordeliers, Capuchins, and Recollects; the second comprehends the nuns of St. Clare; and the third, several persons of both sexes, who live at liberty: and these are what we call the *third order*. See **FRANCISCANS, &c.**

Of this order, which was only established for secular persons, several of both sexes, to attain the greater perfection, have afterwards commenced religious, and formed various congregations, under various names; as "Religious Penitents of the Third Order," &c.

THIRD Point, or *Tierce-point*, in *Architecture*, the point of section in the vertex of an equilateral triangle.

Arches or vaults of the third point, called by the Italians *diterzo acuto*, are those consisting of two arcs of a circle meeting in an angle at top. See **ARCH**.

THIRD Point, in *Perspective*. See **POINT**.

THIRD Rate. See **RATE**.

THIRD Subsidy Duty. See **DUTY**.

THIRD Sound, in *Music*. See **TERZO Suono, TARTINI, and STILLINGFLEET**.

THIRD Year, Tithe of the. See **TITHE**.

THIRDENDALE, a liquid measure used at Salisbury, containing three pints.

THIRDINGS, the third year of the corn or grain growing on the ground at the tenant's death, due to the lord for an heriot, within the manor of Turfat, in Herefordshire.

THIRLAGE, or *Thirlage to Mills*, in *Rural Economy*, a contract or power authorized by law, to prevent the tenants of certain districts from carrying their corn to be ground any where else than at a particular mill. It was a practice which formerly prevailed much; and it was too often used as an engine of oppression, that proved extremely galling to those who were obliged to submit to it, but which at present is nearly, if not wholly done away, except in certain places.

The account of the origin and nature of this oppressive practice,

THIRLAGE.

practice, which has been given by the author of the original Agricultural Survey of East Lothian, in the latter district of country, may not be uninteresting to the curious inquirer. It is conceived that there, in former times, corn was reduced into meal, as in ancient Rome, by a hand-mill, which was called a *quern*; and which was used in the remote parts of the Highlands of Scotland long after the year 1745.

It is certain, however, that the water machine called the mill, for the grinding of oats into meal, is of high antiquity in the same country; and as it was introduced before the period of record, it may be fairly said "caput inter nubilia condit." But from the ancient name of one of the duties, *knave'ship*, which will be afterwards explained, the mill would seem to be of Saxon original.

It seems also natural, that a person who possessed a stream of water upon his estate, should be invited by his neighbours to be at the expence of erecting a mill upon this stream; and that they, on the other hand, should *thirle*, that is, astrict and bind their lands, in all time coming, to use and frequent this mill with their corns, and to pay a certain proportion of the meal according to the universal mode then practised of paying in kind for the grinding of it.

Anciently, it is contended, there is reason to believe, the mills were at first erected upon ecclesiastical lands, and belonged to the clergy.

It is stated, that there are three different species of this sort of servitude known and acknowledged in the law of the above country; but of these, two only belong properly to rural economy; however, in order more thoroughly to understand the subject, the whole may be shortly explained.

It is noticed, that the first and the lightest species of thirlage, is called the *thirlage of grindable grain*, and it means that the tenants and possessors of the astricted lands (in the law of the above country the *servient tenement*) shall be obliged to resort to the mill (the *dominant tenement*) to which these lands have been astricted, with all the oats and barley they shall use for food, and there pay certain dues for the grinding of them.

The second, and the oppressive thirlage, is, it is said, called the *thirlage of growing corn*. By this covenant of thirlage, it is stated, that every ounce of corn produced upon the servient lands, let the quantity be ever so great, must be brought to the dominant mill, and there manufactured into meal, and the covenanted or accustomed duties paid.

It is suggested, that the only limitation that this severe thirlage admitted of, was in favour of seed and of horse corn.

Sometimes a special covenant was made, by which the possessors of the servient lands paid what was called *dry multure*; that is, they paid a quantity of corn to purchase the freedom of going to market with the remainder in the same state; and where constant immemorial usage has sanctioned this custom, the courts of law generally, it is said, have so far mitigated the severity of this species of thirlage, as to find, that the proprietor of the dominant mill can demand no more than that quantity of *dry multure*, which the immemorial usage has established. Such decisions are asserted to be grounded upon the principle of a presumed contract, of which the record or memory has been lost betwixt these parties, whereby the one agreed to pay, and the other to receive, the commutation fixed by the usage.

The third and last species of thirlage is, it is observed, called the *thirlage of *inveſta et illata**, and belongs properly to *urban* tenements: the meaning of it is, that corn, wherever produced, if brought for consumption within the boundaries of the dominant mill, must be carried to the mill and manufactured there, and pay the accustomed duties.

It is stated that this species of thirlage existed in most of the boroughs of the above country; and that the mill generally belongs to the incorporation, where the borough holds directly of the crown, or what are called royal boroughs. But where a borough holds of a subject superior (the lord of the manor), the mill generally belongs to the superior, and the accustomed duties are paid to him, or to his tenant in the mill.

It is to be observed, the writer says, that in all these thirlages, it was the land of the servient tenement that was bound; and that although it should pass by purchase through twenty different hands, every purchaser, and all his people upon these lands, were equally bound to frequent the dominant mill.

It is further noticed, that there were also three different species of duties paid at the dominant mill; as, first, the *multure* (*multura*, grinding); secondly, the *bannock* (loaf); and, thirdly, the *knave'ship*.

It is remarked, that the first of these duties belonged to the heritor and proprietor of the mill; and seems evidently to have been the fine or *premium*, originally settled, as the inducement for his being at the expence of erecting the mill, and for supporting the machinery of it in future. The *bannock* was the duty paid to the miller; and the *knave'ship* the duty paid to the under servants in the mill.

It is stated, that the quantity of meal paid under the name of multure, varied considerably in different counties, and even at different mills. It has been known as high as the eleventh boll, and sometimes as low as the twenty-second boll; and in one particular instance so small as the thirty-second: but it may be taken, on the average, at nearly the seventeenth boll.

The other duties were also various; but they may, it is supposed, be taken jointly as equal to the half, or from that to three-fourths of the multure.

But wholly independent of these several duties, the possessors of the servient tenement were, it is said, bound to perform certain personal services to the mill and its appendages: for instance, when the dam-dyke, or the rampart that directs the stream of water from the river to the mill wanted repair, or when the aqueducts to and from the mill required to be scoured, the people of the servient tenement must turn out and perform these works. When the roof of the house in which the mill stood decayed, they must find thatch for making that repair, and they must put it on. When grind-stones were wanted, or an axle, or any other part of the machinery that required a heavy carriage, they must go with their horses and carriage to the nearest place (whatever might be the distance) to bring these articles to the mill.

But this species of thirlage, it is believed, never was known in the above county; or that at least, if it was, it has long since been forgot. Besides, it is noticed, that there was another circumstance peculiarly fortunate, which put it in the power of most of the landed proprietors of that county, without difficulty, to emancipate their tenants from the thirlage even of *grindable grain*, namely, that the landlord almost universally was proprietor both of the dominant and servient tenement; and that as he astricted his tenants to his own mill by a covenant in the lease, progressively as the leases of the mills expired, the landlords in general emancipated their tenants from every species of thirlage, at a conversion of twenty shillings *per* plough, which was paid by the tenant; and he and his servants were left at perfect freedom to resort to any mill, where they could get their work best done, and at the lowest rate.

The case, however, it is remarked, was widely different

in many parts of the north of the above country; and it is known, from what has already been mentioned, that there were many estates, or *servient tenements*, belonging to one proprietor, which were allotted to mills, or the *dominant tenements*, belonging to another proprietor, and that not a few of these thirlages were the severe one of *growing corns*.

The writer does not think it here necessary to inquire whether these mills were originally erected by the clergy, and since the reformation in religion, have passed into the hands of laymen; or whether, perhaps, if mills are truly of Saxon origin, they were generally, and at once introduced into the above country, when under the Saxons, who certainly were, it is thought, a more enlightened people than the Scottish and Pictish inhabitants of the North, whose ignorance, of course, may have led them more generally to subject themselves in the servitude of thirlage, to invite their clergy, or a few of the more wealthy among them, to undertake the arduous task of erecting mills.

From the near analogy betwixt tithes and thirlage, it has appeared to the writer a matter of just surprize, that the parliament of the above country, which, in the course of a preceding century, first authorised the valuing of tithes for the purpose of fixing a *modus* of payment, and afterwards compelled the lay titulars (proprietors) to sell their tithes at nine, and in some cases at six years' purchase, to the proprietors of the lands, did not introduce a fixed *modus* for thirlage, which certainly operated like tithes, as a tax upon industry, to bar, or at least to retard agricultural improvement in its progress. See TITHE.

THIRLBY, STYAN, LL.D. in *Biography*, a learned critic, was born about the year 1692 at Leicester, and finished his education at Jesus college, Cambridge, blending promising talents with self-conceit, litigiousness of temper, and a habit of intemperance. He appeared at an early age as a writer of controversial pamphlets, and thus acquiring some degree of reputation, obtained the fellowship of his college at the age of about 21 years. In maturer life he probably applied to study with greater diligence, for his edition of Justin Martyr, to which he was indebted for literary reputation, was published in 1722. Versatile in his disposition, he diverted his attention at this time from divinity to physic, and accepted the post of librarian to the duke of Chandos. In this station he continued for a short time, and being under a necessity of quitting it, he became first a student in civil law, and afterwards in common law. Weary of these pursuits, he resided in the house of his former pupil, sir Edward Walpole, by whose interest he obtained a sinecure place in the port of London, of the value of about 100*l.* a-year. Upon leaving this asylum, he took private lodgings; but continued to indulge his habit of sitting and intoxication. He is said to have contributed some notes to Theobald's edition of Shakspeare; but his self-indulgence and indolence rendered him unfit for mental exertion, and he closed his career in December 1753. His edition of Justin Martyr, censured by some, but regarded upon the whole as a valuable performance, contains Justin's two apologies, and his dialogue with Tryphon the Jew, Greek and Latin, with notes and emendations by the editor, and select notes by former editors. Nichols's Lit. Anecd. Gen. Biog.

THIRLWAL CASTLE, in *Geography*, a boundary fortress between England and Scotland, on the Picts' Wall; 3 miles N.W. of Haltwessel.

THIRON *de Gardais*, a town of France, in the department of the Eure and Loire, 21 miles S.W. of Chartres.

VOL. XXXV.

THIRSK, or THRUSK, a borough and market-town in the wapentake of Birdforth, North Riding of the county of York, England; is 23 miles N.W. by N. from the city of York, and 223 miles N.N.W. from London. It is situated in a plain, nearly furrounded by hills, on the banks of a rivulet called Cod-beck, which divides the town into two parts, respectively named the Old Town and the New, which are connected by two small stone bridges. The two towns are distinct, as far as relates to the election of members; but in all other respects are considered as one. The civil government is vested in a bailiff, annually chosen by the burgage holders. The New Town stands within the precincts of the ancient castle of the Mowbrays. In the centre of the town is the market-place; which would be one of the finest in the county, were it not for the tolbooth and shambles, now in a ruinous condition. The market is held on Mondays, and is well supplied with all kinds of provisions. Five fairs are held annually for horned cattle, sheep, leather, and woollen cloth. These fairs attract a considerable number of dealers, and, with the advantage of the great North road from York, are very beneficial to the town, and in some degree supply the want of manufactures, of which here are only a small quantity of coarse linens and facking, and a few bridles and saddles. The population, as returned to parliament in the year 1811, consisted of 2155 persons, occupying 549 houses. The parish church stands on a rising ground at the northern extremity of the town. The roof, which is elliptical, and of oak, ornamented with carving, is supported by a double row of pillars and pointed arches. In the south wall of the chancel, near the altar, are three ornamented stone seats. The church is generally supposed to have been built out of the ruins of the ancient castle, which was demolished in the reign of Henry II. A moat and rampart are still to be seen, but no vestige of the building remains; and in Camden's time, it was nearly in the same state. It had once, however, been a place of great strength, when held by the potent Mowbray family. It was here that Roger de Mowbray began his rebellion against Henry II. and joined the king of Scotland against his own sovereign. The revolt was suppressed, and the castle of Thirsk, as well as several others belonging to the rebellious lords, were by the king's order destroyed. Besides the parish church, the Calvinists, the Quakers, and the Methodists, have their respective meeting-houses. Here is also a School of Industry for poor girls, who are clothed and taught reading, writing, and arithmetic, plain work, knitting, &c.

That division of the town called *Old Thirsk*, is a borough by prescription, and returns two members to parliament. The right of election is in the occupiers of burgage tenements, now only fifty in number, of which forty-nine are the property of sir Thomas Frankland, bart. Old Thirsk consists of a range of cottages on each side of the turnpike road leading from York to Stockton, and of two squares surrounded by the same kind of buildings. In one of these squares, called St. James's Green, the cattle fairs are held; the other is the site of an ancient church, of which, time has long since swept away every vestige. In the latter of these squares is an elm-tree of venerable antiquity, from which the place takes its name, Hawm (that is Elm) Green; and under the shade of whose branches the members of parliament are elected. One of the chief inconveniences of Thirsk and the adjacent country, is the scarcity and high price of coal, which is brought from the county of Durham in small carts, containing from eighteen to twenty-two bushels, varying in price according to the season.

In the vicinity of the town is Byland abbey, which was founded

founded in the year 1177, by Roger de Mowbray, when a stately monastery and church were erected, and dedicated to the Virgin Mary. This abbey continued to flourish till the general dissolution in 1540, when the site and most of the demesnes were granted to sir William Pickering. At present, the ruins and site belong to the honourable family of Stapylton.

Near the base of the Hambleton hills, within four miles of Thirsk, is Thirkleby-Hall, the seat of sir Thomas Frankland, bart. The walks and pleasure-grounds are extensive and well laid out; and the house is an elegant modern structure.—*Beauties of England and Wales*, vol. xvi. Yorkshire; by J. Bigland.

THIRST, a painful sensation, occasioned by a vellication of the nerves of the throat or fauces, and producing a desire of drinking. See **DIGESTION**.

Thirst may be sometimes eluded by rolling a clean bullet or a pebble in the mouth, which occasions an extraordinary issue of saliva to moisten the throat, &c.

Mr. Boyle mentions a man who could easily abstain from drinking for nine days, and yet have his diet nothing more liquid than usual; the secretions of urine, sweat, &c. being performed all the while regularly, and in the same quantity as usual.

In dropsical cases, where there is not a right secretion of the urine by the renal glands, and the vessels and parts of the body are loaded with too great a quantity of serous humours, a great moderation in drink might be attended with good success, provided some liquor could be found out to allay that uneasy sensation. Probably this would be best performed by mucilages acidulated with spirit of vitriol or sulphur, or jellies with juice of lemon, &c. and that a small quantity of such a composition, now and then used, might be of as much real service, in quenching thirst, as draughts of liquors, which increase the symptoms.

In feverish disorders, the patient is frequently tormented with a violent thirst, which is moderated by acidulating the barley-water, or sage-tea, with spirit of vitriol, or with lemon-juice: but by nothing so much, as allowing the patient some slices of an orange. Pringle, *Observ. on Diseases of the Army*, p. 135.

THIRSTY SOUND, in *Geography*, an inlet or bay on the N.E. coast of New Holland, so called by Cook in 1770, because it afforded no fresh water. It lies in S. lat. 22° 10', and W. long. 210° 18'; and may be known by a group of small islands lying under the shore, from two to five leagues distant, in the direction of N.W., and by another group of islands that lie right before it, between three and four leagues out at sea. In this inlet is good anchorage in 7, 6, 5, and 4 fathom; and here are places very convenient for laying a ship down, where, at spring-tides, the water does not rise less than 16 or 18 feet. The N.W. point of Thirsty Sound was called "Pier-Head."

THIRTEEN ISLANDS, a cluster of islands in the Pacific ocean, among the New Carolinas, so named by Capt. Wilson. N. lat. of the most southerly 7° 16'. E. long. 144° 30'.

THISATON, a river of Canada, which runs into lake Huron, N. lat. 46°. W. long. 84°.

THISMA, a name used by some for any subterranean vein, or bed of a mineral.

THISTLE, in *Agriculture*, a well-known prickly troublesome weed, common in corn and other fields. It has been observed, that wherever thistles grow naturally, it is a sure sign that the land is strong, and of a tolerable good quality; but that they are at the same time a great annoyance to every plant intended to be cultivated. And it has

also been well remarked, that there are no weed-plants over which the economical farmer ought to keep a more watchful eye than the thistle tribe, as they are not only wholly useless, but occupy much ground, and being furnished with downy seeds, are capable of being multiplied and carried almost to any distance. Besides, they do much mischief by impeding the work both in handling hay and corn crops. It is of course a matter of much consequence to be well acquainted with the qualities of each kind, in order to enable the farmer to judge with certainty how far and by what means their destruction may be effected in the most certain and ready manner.

There are a great many sorts of thistles; and those which chiefly deserve the attention of the farmer, are the *annual*, *biennial*, and *perennial* kinds.

There are four of these plants belonging to the first division or sort, namely, the *musk-thistle*, which grows to the height of two or three feet; the heads hang down, and the flowers smell somewhat like musk. It is frequently found occupying whole fields, particularly where the lands are of a chalky or barren quality; and sending forth flowers in July and the following month in great abundance. The *milk-thistle*, which is found plentiful in most waste places, and upon old banks, being well known by its beautiful large leaves, which are variegated with white spots and veins, as if they had been sprinkled with milk. The flowering season of this plant is in August, or thereabouts. The *swelled* or *curled* thistle, which is frequently met with on banks, and by road-sides, but seldom intruding itself into fields or pastures. Its time of flowering is June and the following month. See **CARDUUS**.

And the *common saw-thistle*, which is a very troublesome weed in fields and gardens; it is found in some situations that the plant is smooth, but in others that it is rough, being prickly on the margins and mid-ribs of the leaves, and also on the peduncles and calyces of the flowers, and the stems or stalks abound with a lactescent or milky juice. See **SOXENEA**.

But in the second division, or biennial kind, there are not more than three, as the *spear* or *bull-thistle*, which rises about three or four feet in height, the extremity of each leaf running out into a long sharp point, remarkably prickly: hence, in some places it is called by the name of the bull-thistle. It has large heads of flowers, and commonly grows by the sides of roads, near dunghills, and not unfrequently in fields and pastures, flowering in June and the following month: the *marsh-thistle*, which grows very tall and prickly, having numerous heads of flowers, small and of a red colour, growing abundantly in wet meadows and in woods, flowering in July and the month which succeeds it. See **CARDUUS**.

And the *cotton-thistle*, which is found plentifully in uncultivated places in many parts. The roots are long and fibrous, and send forth several oblong sharp-pointed whitish-green sinuated leaves, covered with a cottony down, and set with spines on their edges. In the middle of these shoots up a stalk, to the height of five or six feet, divided towards the top into diverse branches, set with leaves at their joints, and having jagged, leafy borders running along them, edged with spines, as has the main stalk also. Each branch terminates with a scaly head of reddish purple florets, having narrow tubes, and cut at their brim into five teeth. They contain flowers, which are succeeded by small oblong seeds crowned with down. The time of its flowering is about July, for the most part. See **ONORODIUM**.

And in the third division or sort there are only two; as

THISTLE.

the *corn sow-thistle*, which is a very troublesome weed in arable land, flowering in July and the succeeding month. See SONCHUS.

And the *common* or *field-thistle*, which has many provincial names in different places, as the *horse-thistle*, the *curled thistle*, &c. This is a thistle which is more general in its growth than any of the others, being found not only by the sides of roads, but also in arable and pasture lands, and it is remarkably prickly, growing from two to three feet in height, but the heads of the flowers are small, and of a purplish colour, though sometimes white; it flowers in July, or about that period. See CARDUS and SERRATULA.

It is obvious, from what has been said, that the annual and biennial sorts of thistles may be readily removed, by preventing their running to seed and disseminating themselves over the land; which is best effected probably by carefully eradicating them, or frequently mowing them over closely by the surface, and rolling. But in the perennial sorts, from their roots continuing in the earth, increasing and throwing out new shoots or stems every year, there is much more difficulty in extirpating them, and they, perhaps, can be no other way completely destroyed than by rooting them out on arable land by trench or deep ploughing and frequent harrowings, or by fallowing or laying the land down to pasture; for the first of these sorts seldom appears in pasture lands. But for destroying the common thistles, the best method is perhaps by cutting them over in the bleeding season frequently by proper implements. The writer of the Berkshire Agricultural Report, who thinks them particularly noxious, troublesome, and inconvenient among the corn and grass crops, proposes drawing them up by an implement of the forceps kind, somewhat similar to that described under the head noticed below, especially the sort which is termed *serratula arvensis*; or if they be cut over about an inch above the surface of the ground, it is believed they will be liable to rot, on account of the stem being filled with water. They also frequently bleed to death when cut over in this way about the month of August, as hinted at above. See THISTLE-Drawer.

Others suggest that thistles might probably be destroyed in arable land by continued fallowing for one or two summers; with such repeated ploughing and hoeing as wholly to prevent their vegetating: but as such a progress would be tedious and expensive, an easy, expeditious, and effectual mode of eradicating them in this case, seems equally wanting and desirable, as in that of grass lands. Thistles are likewise very troublesome in hedges, especially those of the sow and the large rough kinds, and should constantly be rooted out and removed as soon as possible, as no hedge can go on well that is much infested with them. See THISTLE-Cutter, WEED, and WEEDING.

It may be noticed, that by an excellent regulation in France, a farmer may sue his neighbour who neglects to thistle his land at the proper seasons, or may employ people to do it at the other's expense. And it were to be wished that a similar law was enacted here, to prevent the wide-spreading mischief occasioned by the seeding of this pernicious weed; among which may be reckoned, besides its choking the young corn, that if wheat in particular be not well thistled, the reapers take up the grips so tenderly, lest they should prick themselves, that by their loose handling of them, they sometimes leave upon the ground corn enough to sow the whole field. There is much inconvenience often experienced too in working hay from them.

Something in the same way as above has also lately been

done here, especially in regard to the removal of them from the sides of highways and roads.

Though the sow-thistle has commonly been considered as a troublesome and injurious weed in tillage lands, it has lately been conceived by some to possess no small degree of nutrient power; and on this ground it has been suggested by the writer of the "Experienced Farmer," that it may be a plant of considerable fattening properties when properly raised and cultivated. When taken young, and cut or broken, it produces something, it is said, like cream; and he has noticed that many animals eat it in preference to every other plant now in vogue. Sheep, when in clover, &c. will feed upon it so greedily as to eat the very roots. Pigs likewise prefer it to almost any other green food. Rabbits will breed more speedily when fed with sow-thistles, than with any other food he knows of, except dandelion; which is of the same nature: and is now sold in Covent Garden market to the breeders of tame rabbits, to make the does take buck more readily. A man of his acquaintance, who was allowed better skill with stallions than the generality of people, used to search for sow-thistles, and give them to his horses to make them serve mares more readily and effectually. When he could not get sow-thistles, he fed them, it is said, with new laid eggs and milk, or cream, if he could get it; but he preferred sow-thistles or dandelion to any thing.

And there is, he contends, a well-known and remarkable proof of the nourishing and feeding quality of the sow-thistle, in the fat wether sheep fed to such an amazing size by Mr. Trimnel, of Bicker-fen, near Boston, upon fen-land. This sheep, it is said, was bred by Mr. Hutchinson, in Hail-fen, from a ram bred by Mr. Robinson of Kirby, near Sleaford. He never ate any corn, oil-cake, or other similar dry food, but fed wholly on grass and herbage. Being turned with many other sheep into a field of clover, he was observed first to search for the sow-thistles, and would eat no other food while any of these could be found in the parts of the field that were hurdled off successively, a little at a time. None of the other sheep that fed with him, however, shewed any extraordinary liking for the sow-thistle. A small hut was built for him in the field to repose under in hot weather: and when the part that was hurdled off became bare of food, his attendants, on account of his liking for sow-thistles, gathered a quantity of them for him, which they gave him at particular hours, three times a day, from two to five pounds at a meal.

It is added, that when standing on his feet, he measured only two feet six inches high: he was weighed once a month, and weighed alive twenty-six stone, at fourteen pounds to the stone. He gained only one pound the last month: and as it was judged, therefore, that he was quite ripe, and would not increase any more, but might possibly lose weight the next month, he was killed on the 13th of October 1791, by Mr. Isaac Lumby, of Bicker, being then a four-shear, or four-year-old sheep.

The writer further states, that the skin, hung up by the nose part, measured ten feet two inches from the point of the nose to the tip of the tail, and was sold for 7s. 6d. in the common course of business. And that the carcase measured five feet from the nose to the tail; the rump or cushion eight inches and a half in depth; plate or fore-flank the same thickness; breast end seven inches; and was one yard five inches and a half round the collar. That the legs were reckoned at 40lbs. each; but if cut haunch of venison fashion, they would, it is said, have weighed 50lbs. each. Mr. Lumby was offered 2s. a pound for them; so that he could have sold the two legs alone for 10l. when so cut.

This is certainly a remarkable instance of fatness, but it might probably depend more on the disposition of the animal to take on fat, than the fattening quality of the thistle or food on which the sheep was fed. Many further trials are necessary to fully ascertain the point.

THISTLE, *Blessed*, *carduus benedictus*, vel *cnicus*. See CENTAUREA.

As an article of the *Materia Medica*, the blessed thistle, which is the hairy wild *cnicus* of Miller, and the *centaurea benedicta* of Linnæus, was formerly much used in infusion, as a gentle emetic, in fevers and certain nauseae.

Dr. Lewis has often observed excellent effects from a light infusion of *carduus*, in weakness of appetite and indigestion, where the stomach was injured by irregularities, or oppressed by viscid phlegm; nor has he found any one medicine of the bitter kind to sit so easily on weak stomachs, or to heat so little. These infusions, taken freely, promote the natural secretions. Drank warm in bed, they commonly increase perspiration or excite sweat; and as they act with great mildness, not heating or irritating considerably, they have been used, in this intention, in acute as well as chronic cases. The seeds, which, as well as the leaves, have a considerably bitter taste, have sometimes been used as sudorifics or diaphoretics, in the form of an emulsion. Cold water poured on the leaves, extracts, in an hour or two, a light grateful bitterness; by standing long upon the plant, the liquor becomes disagreeable: a strong decoction is very nauseous and offensive to the stomach. The extracts, obtained by inspissating both the cold infusion and decoction, have the same differences as the liquors themselves. Rectified spirit extracts, in a short time, the light bitter part of this plant, but does not take up the nauseous near so easily as water. On keeping the watery extracts for some months, a considerable quantity of saline matter was formed on the surface, in small crystals, resembling in shape those of nitre, in the taste bitterish, with an impression of coolness. Lewis's *Mat. Med.* See CENTAUREA *Benedicta*.

Some distil a water from it, which they use in cordial and sudorific potions.

THISTLE, *Carlina*. See CARLINA.

The root of the *carlina acaulis* of Linnæus, is supposed to be diaphoretic, antihysterical, and anthelmintic. It has been greatly esteemed by some foreign physicians, in acute malignant as well as in chronic diseases, and given in substance from a scruple to a drachm, and in infusion from one to two drachms and more. It is rarely to be met with in our shops. See CARLINA *Gaulescens*.

THISTLE, *Distaff*. See ATRACTYLIS.

The roots of the *atractylis gummifera* of Linnæus, or pine-thistle, which is a native of Italy and the island of Candy, yield, if wounded when fresh, a viscous milky juice, which concretes into tenacious masses, at first whitish and resembling wax, but when much handled growing black; supposed to be the *ixion*, and *acanthina massliche* of the ancients. The juice is said to have been formerly chewed for the same purposes as mastich, and the root itself of the same virtue with that of the earline thistle. Lewis.

THISTLE, *Fish*, a species of *Carduus*; which see.

THISTLE, *Fuller's*. See DIPSACUS and TEASEL.

THISTLE, *Gentle*, a species of *Carduus*; which see.

THISTLE, *Globe*. See ECHINOPS.

THISTLE, *Golden*. See SCOLYMUS.

THISTLE, *Hedge-hog*, a species of *Cardus*; which see.

THISTLE, *Ladies*, or *Milk*, a species of *Carduus*; which see.

THISTLE, *Melon*. See CACTUS.

THISTLE, *Sow*. See SONCHUS.

THISTLE, *Downy Sow*. See ANDRYALA.

THISTLE, *Star*. See CENTAUREA.

THISTLE, *Torch*. See CACTUS.

THISTLE, *Woolly*. See ONOPORDUM.

THISTLE-CUTTER, in *Agriculture*, a tool of the sward-dressing kind, for cutting up thistles and other coarse weeds and plants.

An effective implement of this sort has lately been invented, delineated, and described by Mr. Amos, in his work on "Agriculture and Planting."

The plan of the whole machine, when complete, is that of a sort of square, in which the leading share is made of cast-steel, in the form of an isosceles triangle, whose equal sides are fourteen inches long, and its base twelve inches, being about one-eighth of an inch thick in the middle, tapering to a very fine edge on the outsides. There are four pieces of ash-wood, three inches square, and two feet four inches long, to which the scythes are fixed, and which are called the scythe-handles. There are also four scythes, three feet long from point to point, four inches broad at the widest part, made of cast-steel, and which, the inventor says, are manufactured by Messrs. Hunt and Company, at their cast-steel manufactory, Brades, Birmingham. There are likewise four other pieces of ash-wood, three inches square and two feet five inches long, for throwing the two hindmost scythes to their proper distance, and which are braced two and two together by four bars, which are one by two inches square, and eighteen inches and one-fourth long. And there is a main piece of ash-wood, three by four inches square, and five and a half feet long, to which all the other pieces are fixed by hooks, and eye-bolts, by means of which the scythe-handles act as it were upon hinges, and the scythes are thereby made to form the same parallel line with the surface of the land, whether it be concave, convex, or level. For this purpose, it is suggested that it might be useful to make a joint in the middle of this piece, where the land is uneven. And in the fore part of this piece a sawgate is to be made, three-fourths of an inch from the under side, at the hind part of the share, and one inch from the under side at the front of the wood, which gives an elevation to the point of the share, to receive the share where it is fixed.

There are four iron braces, one of the ends of which are fixed in the scythe-handles, and the other ends to the under sides of the scythes by a screw. There is a staple, to which the chain and swinging-tree is fixed, and by which the machine is drawn. There are two mortise-holes on the sides, which receive the tenons of two upright studs, to which pullies are fixed for lifting the scythes off the ground, where there is any thing to obstruct them or retard their progress. Each of these studs is one and a half by four inches square, and three feet long. Two small pullies are fixed on each side of these upright studs. Through the pullies of the foremost stud, a small rope passes (one end of which is fixed to the outsides of the iron braces), and likewise through the pullies of the hindmost stud, and then the two ropes unite at about two or three feet behind the whole machine; and through the pullies of the hindmost stud pass two other small ropes (one end of each being fixed to the outside of the hindmost iron braces), and then the four ropes unite together, where the manager holds them as a coachman does the reins of four horses. By means of these ropes the scythes may be lifted to any degree of elevation, by which contrivance any unevenness of the ground, or other obstructions on its surface, such as stones, roots, ant-hills, &c. &c. may be easily avoided and passed by.

The swinging-tree is thirty-three inches long, and the chain

chain which hooks into the staple for drawing the machine by, is thirty inches long.

The whole of the scythes, when properly fixed, projects beyond the wood, and cut the thistles three-quarters of an inch above the surface of the ground.

In cases where the scythes want sharpening, it is observed that they may be reared perpendicularly up, or taken off entirely; and that, at the same time, the horses should be ungeared and taken away.

In using the machine, it is advised by the ingenious inventor, that as soon as the thistles are in full flower it should be set to work, the length way of the ridges; and that if the scythes are kept very sharp, it will make excellent work. And when the thistles have been cut, they should lie a day or two, it is said, to perish by the loss of their sap-juice: the ground must then be cleared, and the close or field rolled, the cross way of the ridges, with a very heavy roller, which so crushes the hollow stumps, and renders them so pervious to water, that their roots soon rot and are destroyed. But to expedite the operation of the implement, and the destruction of the weeds and plants, the land should be cleaned of all kinds of rubbish, the latter end of March or beginning of April, being dressed with the sward-dresser, and then rolled the cross way of the land, or ridges, with a weighty roller, as just mentioned. See *Sward-Dresser*.

THISTLE-Drawer, an useful implement of the forceps kind, which is extremely beneficial in drawing up the common field-thistle and some other strong sorts of weeds. It may be constructed either of wood or iron, in the latter case having sockets for receiving wooden handles. When made of wood, it should be of the hard and less brittle kind, as good tough ash. It is usually formed from two to three feet in length, having six notches or blunt teeth cut in each blade, at the bottom part, where it bites or seizes the plants, and each arm well fitted to the other, turning upon a strong pivot or pin. In its operation the thistle is seized close to the ground and firmly held, so as to be drawn out with considerable length of root. It has been long in use in the northern parts of Lancashire; and is said to be lately introduced from Wiltshire into the county of Gloucestershire, in the agriculture report of that district. It is an useful and effective tool for the above purpose, and only costs about two shillings when made of wood, and three or four when of iron. It has long been known in the first of the above counties by the provincial name of *Gripes*.

THISTLE-Fly, in *Natural History*, a small fly produced from a fly-worm hatching in the protuberances of the *carduus hæmorrhoidalis*. In the protuberances of this thistle, while they are closed in all parts, the worm of this fly, from whose injuring it, at the time of depositing the egg from which it was hatched, the protuberances arose, undergoes its last transformation. It here makes of its own skin a shell in form of an egg, within which it puts on the nymph state. When this nymph becomes a living fly, the least part of its difficulty is the finding its way out of this shell; it has a stronger prison than that, and before it can obtain its liberty, must force its way through the much more closely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult work, but that of inflating its head, and throwing out the bladder or muzzle with which all these creatures are provided in this state. See *THISTLE-Galls*.

This is a difficult operation, and many of the creatures perish in the attempt; but what much forwards the success of it, in many cases is, that the stalk of the thistle often becomes naturally half rotten before the time of the fly's egress. Reaumur, *Hist. Inf.* vol. iv. p. 338.

THISTLE-Galls, a name given by the more accurate authors to the protuberances on the stalk of a species of thistle, called by authors *carduus hæmorrhoidalis*, from those tubercles, which are supposed to resemble those of the hæmorrhoidal veins in persons subject to the piles. These have been supposed a natural production of the plant; but they are far otherwise. The whole history of them is, that a certain species of fly always deposits its eggs on the stalks; and the young ones, when hatched, gnaw their way into the substance of the stalks, and the copious derivation of the juice, occasioned by their sucking, produces the tubercles which are found on it.

These tubercles are of a roundish or oblong figure, and are of various sizes, from that of a pea to the bigness of a nutmeg; they are much harder than the rest of the stalk, approaching to a woody structure; when cut open, they are found to contain each several oblong and narrow cells; these have no communication with one another, and are each inhabited by a small white worm, which has two hooks at the head; with these it breaks the fibres of the plant, in order to get at its juices. When it has arrived at the time of its change into the nymph state, it ceases to eat, and drawing up its body much shorter than usual, its skin hardens, and forms a shell, under which it changes into a very beautiful two-winged fly; the wings are whitish and transparent in the middle; and at the edges surrounded with black in the form of a chain of figures like the letter Z; the body and breast of this fly are of a beautiful black, with some slight variations of yellow, with which the shoulders are streaked; the anterior part of the head is white, and its back-part edged with a yellow down; the antennæ are reddish, and the legs are partly black, and partly of a fine clear brown.

In observing the changes of the worms of these galls, there are often observed some which go through them in a different manner from the rest, and finally produce a very different species of fly. These are the progeny of the eggs of some other species of fly, whose worm being carnivorous, is lodged by the art of its parents, while it is yet in the egg state, in the substance of this gall, there to prey upon the defenceless inhabitants.

There are many species of galls the inhabitants of which are exposed to enemies. In those it is common to find the proper inhabitant and the devourer in the same cell; the one feeding on the juices of the plant, the other on its juices; but this is not the case here, these worms immediately destroying the proper inhabitants, and being found always alone in their cells. Reaumur, *Hist. Inf.* vol. vi. p. 221.

THISTLE, *Order of*. See *ANDREW*.

THISTLE, *our Lady of the*, was also a military order, instituted in 1370, by Louis II. duke of Bourbon. It consisted of twenty-six knights, of which that prince and his successors were the chiefs. Their badge was a sky-blue girdle; and, on solemn occasions, a mantle of the same colour, with a gold collar, interwoven with flower-de-luces; among which was the word *esperance, hope*, in capitals.

THISTLE-TAKE, a custom in the hundred of Halton, in the county of Chester, whereby, if in driving beasts over the common, the driver permits them to graze, or take but a thistle, he shall pay a halfpenny a beast to the lord of the fee.

At *Fiskerton*, in Nottinghamshire, by ancient custom, if a nati e, or cottager, killed a swine above a year old, he paid the lord one penny, which was also called thistle-take.

THIVA, or *STIBES*, in *Geography*, a town of European Turkey,

Turkey, in the province of Livadia, anciently called "Thebes," and the capital of Bœotia, situated on a rising ground between two small rivers, supposed to be the Ilmenus and Dirce of the ancients. (See THEBÆ.) The town is of an oval form, about three miles in circumference, and the houses are higher and better built than is usual in most parts of Greece. It contains four or five thousand inhabitants, about half Turks and half Christians, which latter have several churches, not remarkable for any thing except some few inscriptions to be seen upon the pavement of the cathedral. The air of the country about Thebes is thick and foggy, whence the ancient inhabitants of Bœotia were accounted dull and phlegmatic, and were neither famous for their wit nor valour. (See BŒOTIA.) Epaminondas raised Thebes to its highest pitch of grandeur; after whose death it was not remarkable for its virtues, but misfortunes, till it sunk into its original obscurity; so that its glory took birth with this great man, and with him expired; 28 miles W.N.W. of Athens. N. lat. 38° 25'. E. long. 23° 34'.

THIVIERS, a town of France, in the department of the Dordogne; 7 miles N.W. of Exideuil.

THIULETIS-TSKALI, a river of Georgia, which runs into the Kur.

THIZY, a town of France, in the department of the Rhone and Loire; 27 miles N.W. of Lyons.

THLASIAS, a term used by the ancients to express an enuch made by a compression or contusion of the testicles, not by the cutting them out.

THLASIS, a word used by the ancients to express either a contusion without a wound, or a wound made by some blunt instrument, which contused the parts.

THLASMA, a word sometimes used like *thlasis*, to express a contusion either with or without a wound; sometimes applied particularly to a recess of the cranium inward without a fracture, an accident principally affecting children.

THLASPEOS SEMEN, in the *Materia Medica*, the name of a seed produced by the common *thlaspi arvense siliquis latis*, or common treacle-mustard. It used to be an ingredient in several of our shop compositions, and was esteemed attenuating, deterfive, and aperient, and is said to promote urine and the menses, and to expel the after-birth.

THLASPI, in *Botany*, $\theta\lambda\alpha\sigma\pi\iota$, an ancient name, which Dioscorides tells us, in his book 2. chap. 186, originated in the broken, or pounded, appearance of the seed, alluding, we suppose, to its smallness. The word therefore is derived from $\theta\lambda\alpha\sigma\sigma$, to bruise, or beat. He compares this seed to that of his $\kappa\alpha\tau\alpha\delta\alpha\mu\iota$, our *Lepidium sativum*, or Garden Cress, adding that the seed-vessel is moderately dilated upwards, the flower white, and the plant found about paths, walls, and banks. Every other part of his description, respecting the leaves and stems, is so apposite, that no doubt can remain of his $\theta\lambda\alpha\sigma\pi\iota$ being our Shepherd's Purse, which Dr. Sibthorp found common in Greece and the Archipelago, in the early spring. Linnæus might surely have spared his mark of uncertainty concerning the etymology of the above name, in *Phil. Bot.* 183. But as he translates $\theta\lambda\alpha\sigma\sigma$ by the Latin word *comprimo*, to compress, he, most likely, had in view the *Th. arvense*, which several old writers have taken for the plant of Dioscorides, and whose seed-vessel is very remarkably compressed.—Linn. Gen. 334. Schreb. 437. Willd. Sp. Pl. v. 3. 442. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 683. Compend. ed. 2. 98. Prodr. Fl. Græc. Sibth. v. 2. 7. Brown in Ait. Hort. Kew. v. 4. 80. Juss. 241. Lamarck Illustr. t. 557. Gærtn. t. 141.—Class and order, *Tetradynamia Siliquosa*. Nat. Ord. *Siliquosæ*, Linn. *Crucifera*, Juss.

Gen. Ch. Cal. Perianth inferior, of four ovate, concave,

somewhat spreading, deciduous leaves. Cor. cruciform, equal, of four obovate petals, twice the length of the calyx, with narrow claws. Stam. Filaments six, but half the length of the corolla, the two opposite ones still shorter; anthers pointed. Pist. Germen superior, roundish, compressed, emarginate; style simple, the length of the stamens; stigma obtuse. Peric. Pouch compressed, inversely heart-shaped, emarginate, the style being mostly the length of the notch in which it stands, of two cells, the partition lanceolate, and the valves boat-like, with more or less of a dilated keel. Seeds several in each cell, pendulous, inserted into the sutures, roundish, compressed.

Ess. Ch. Pouch compressed, emarginate, inversely heart-shaped; its valves boat-like, keeled. Seeds several.

Obs. Mr. Brown has very happily separated from this genus the Linnæan *Th. campestre*. That species, on account of its solitary seeds, properly belongs to *Lepidium*, to which genus it, as well as *Th. hirtum*, is removed in the new edition of our *Compendium Fl. Brit.* The same ingenious botanist, of whose elucidation and reformation of the cruciform genera we have spoken under the article TETRADYNAMIA, has founded a new genus, called *Aethionema*, upon *Th. saxatile*, with another species, whose pouch has no valves, and only a single seed. With this latter, a Spanish plant, we are unacquainted; but as the *saxatile* has two cells, and many seeds, we can hardly either disjoin it from *Thlaspi*, or unite it with this, though, it seems, they agree in having an unequal insertion of their calyx-leaves, which in *Thlaspi* is equal; and their longer filaments are either combined, or else toothed near the top. As there are but two species, we presume one of these last characters belongs to each. The question seems at least doubtful, and therefore, without presuming to form an opinion respecting Mr. Brown's *Aethionema monospermum*, we prefer keeping his *saxatile* where it is.

The plants of this genus are herbaceous, and most of them annual, with simple leaves, and numerous corymbose flowers; their surface more frequently smooth, and somewhat glaucous, than pubescent; stem leafy and branched.

1. *Th. peregrinum*. Red Penny-Cress. Linn. Sp. Pl. 901. Willd. n. 1. Scop. Carn. v. 2. 17. (Th. capsula cordata, peregrinum; Bauh. Hist. v. 2. 927, badly copied in Moris. sect. 3. t. 18. f. 30.)—Pouches roundish-heartshaped. Leaves lanceolate, entire.—Native of dry hills, above Heidenchaft in Carniola. Scopoli. Of this very rare plant we have never seen a certain specimen. Scopoli says the stems are a span high, hard, branched, turning reddish, as well as the leaves, as they advance in age. The leaves grow on short stalks. Flowers small, red, with entire ovate petals, and reddish stamens. Anthers yellow, as well as the short style, and the stigma, which last is flat at the top. Seeds two in each cell, ovate, yellowish, slightly rugged, shining, attached to the falcate partition.

2. *Th. arabicum*. Purple Arabian Penny-Cress. Vahl Symb. v. 2. 76. Willd. n. 2. (Th. humile, spica purpurea; Buxb. Cent. 1. 2. t. 2. f. 1. Iberis arabica; Linn. Sp. Pl. 906. Am. Acad. v. 4. Subularia purpurea; Forst. Ægypt.-Arab. 117.)—Pouch nearly orbicular, compressed, with a notch at each extremity. Lower leaves wedge-shaped; upper oblong-heartshaped, entire, clasping the stem.—Native of Arabia and Cappadocia.—The root is tapering, fibrous, annual. Stem more or less branched, round, smooth, from three to six inches high, leafy, corymbose. Leaves an inch long, acute, entire, smooth, rather succulent, slightly stalked. Flowers small, purple or reddish. Pouch light green, with a very broad striated border, much exceeding the style, and notched at the base as well as summit.

THLASPI.

summit. *Seeds* two in each cell. This species appears nearly related to the foregoing, nor should we be greatly surpris'd if they proved one and the same. If Bauhin's delineation of the *pouch* of the former be correct, they must be distinct.

3. *Th. arvensis*. Common Penny-Creeps, or Smooth Mithridate Mustard. Linn. Sp. Pl. 901. Willd. n. 3. Fl. Brit. n. 1. Prodr. Fl. Græc. n. 1. Engl. Bot. t. 1659. Curt. Lond. fasc. 6. t. 43. Fl. Dan. t. 793. (Th. Dioscoridis; Ger. Em. 262. Th. secundum; Matth. Valgr. v. 1. 519. Camer. Epit. 337.)—*Pouch* orbicular, compressed, entire at the base. Leaves oblong, toothed, smooth.—Native of cultivated fields, in most parts of Europe, but not frequent in England. It is annual, flowering in June and July. Dr. Sibthorp met with it in the countries north of Greece. The *root* is small, and tapering. Whole *plant* smooth, about a foot high, branched; the *stem* leafy, angular upwards. *Leaves* two or three inches long, clasping the stem with their arrow-shaped base; their edges wavy and toothed. *Flowers* numerous, small, white. *Pouch* large, erect, almost perfectly orbicular. *Style* much shorter than the notch in which it stands. *Seeds* numerous. The warm pungent taste of this plant is combined with a disagreeable garlick flavour. The *seeds*, as observed in Engl. Bot. "make an ingredient in that nauseous opprobrium of pharmacy, the Mithridate Confection, the receipt for which may be found, with many excellent critical remarks, in Lewis's Dispensatory." See MITHRIDATE.

4. *Th. alliaceum*. Garlick Bastard-Creeps. Linn. Sp. Pl. 901. Willd. n. 4. Ait. n. 2. Jacq. Ic. Rar. t. 121. (Th. allium redolens; Morif. sect. 3. t. 18. f. 28.)—*Pouch* nearly obovate, tumid, with a narrow border. Leaves oblong, obtuse, smooth; somewhat toothed.—Native of the south of Europe. An annual herb, much resembling the last, but the *leaves* are blunter, and less toothed. The *pouches* are very different, having but a slight border at their upper part only, their base being wedge-shaped.

5. *Th. psychine*. Long-styled Bastard-Creeps. Willd. n. 5. (Psychine stylosa; Desfont. Atlant. v. 2. 69. t. 148. Bursa pastoris hirsuta, eruce flore, stilo prominente; Shaw Afric. n. 91. f. 91.)—*Pouch* abrupt. *Style* prominent. Leaves heart-shaped-oblong, toothed, downy, clasping the stem.—Native of the borders of fields in Barbary. *Root* annual. *Herb* larger than the foregoing, and clothed with hoary hairs. *Leaves* rounded, not acute, at the base. *Flowers* pale yellow, as large as the Common Mustard. *Pouch* wedge-shaped, or triangular, being quite abrupt at the end; the *style*, which is as long as the whole pouch, standing prominent at the summit. Willdenow is certainly correct as to the genus.

6. *Th. saxatile*. Rock Bastard-Creeps. Linn. Sp. Pl. 901. Willd. n. 6. Jacq. Austr. t. 236. (Lithothlaspi quantum, carnosu rotundo folio; Column. Ecphr. 279. t. 277. f. 2. Aethionema saxatile; Br. in Ait. Hort. Kew. v. 4. 80.)—*Pouch* nearly orbicular; concave above; convex below. Stems mostly simple. Leaves linear-lanceolate, fleshy, obtuse.—Native of dry hills, and the clefts of rocks, in Italy, Austria, Switzerland, Greece, and the south of France, flowering in April and May. The *root* is perennial, and in some degree woody, though generally marked as annual. *Stems* annual, ascending, six or eight inches high, round, leafy, rarely subdivided. *Leaves* numerous, scattered, on short stalks, glaucous, smooth, entire, three quarters of an inch long; the lower ones rather elliptical. *Flowers* small, pink, numerous, in dense terminal *corymbs*, soon elongated into lax *clusters* of glaucous *pouches*, tinged with pink, each on a slender, spreading, partial stalk; their border

broad, striated, somewhat crenate, emarginate at the top only, where the minute *style* is situated. The shrubby habit; glaucous hue, and very pretty little red *flowers* with a pale-green *calyx*, render this one of the most elegant plants of its natural order. *Iberis saxatilis*, Linn. Sp. Pl. 905, distinguished from this by the accurate Fabius Columna, and figured in the same plate of his work, is so like it, that they are hardly to be known asunder, except by the unequal *petals*, proper to *Iberis*, and the downiness of this latter plant. On a close comparison, the shapes and surfaces of their *seed-vessels* will be found essentially different.

7. *Th. montanum*. Mountain Bastard-Creeps. Linn. Sp. Pl. 902. Willd. n. 9. Ait. n. 7. Jacq. Austr. t. 237. (Th. montanum, bursa pastoris fructu; Column. Ecphr. 275. t. 276. f. 1. Th. præcox; Wulf. in Jacq. Coll. v. 2. 124. t. 9. Lepidium n. 518; Hall. Hist. v. 1. 223. β . Th. alpinum; Jacq. Austr. t. 238. Willd. n. 10. Crantz Austr. fasc. 1. 25. t. 3. f. 1. (Th. minimum; Arduin. Spec. 2. 33. t. 15. f. 2.)

Pouch inversely heart-shaped. Leaves smooth, nearly entire; radical ones obovate, stalked; the rest sessile, clasping the stem. *Petals* thrice as long as the calyx. Stems simple.—Native of stony places, on the lofty mountains of Switzerland, Austria, Dauphiny, and Italy, flowering in April or May. The *roots* are perennial, long, subdivided at the summit, each trailing shoot crowned with a tuft of obovate *leaves*, rarely a little serrated, their size, and the length of their *footstalks*, varying according to luxuriance of soil, or a more or less elevated place of growth. From the centre of each tuft arises a solitary, simple, ascending or upright *stem*, from three inches to a span long, round, smooth, clothed with numerous, alternate, sessile, cordate or arrow-shaped, very rarely toothed, *leaves*, whose base is more or less elongated and acute; their length three quarters of an inch. *Flowers* in solitary terminal *corymbs*, numerous, large, white and handsome; their broad, obovate, spreading *petals* at least thrice as long as the smooth, often purplish, *calyx*. *Pouch* tapering at the base; more or less deeply lobed at the end, with a *style* almost as long as itself, projecting far beyond the lobes. *Seeds* naturally two in each cell, as Jacquin describes them. Haller found one only. This may be accounted for from their being often abortive, as indeed are generally most of the *pouches* themselves, the plant increasing much by root. Having had occasion to study this and the neighbouring species very minutely, in our investigation of Swiss and British plants, we can with confidence maintain the correctness of our synonyms, on the authority of original specimens. Our β alone is entitled to be distinguished as a variety, and that an insignificant one, being merely rendered small in size by its very elevated or exposed situation. The faithful Jacquin himself evidently mistrusted this supposed species, though he says it retained the same habit when cultivated.

8. *Th. alpestris*. Alpine Shepherd's Purse. Linn. Sp. Pl. 903. Willd. n. 12. Fl. Brit. n. 5. Engl. Bot. t. 81. Ait. n. 6. (Th. foliis globulariæ; Raii Syn. ed. 2. 175. ed. 3. 305. Bauh. Hist. v. 2. 926. Th. montanum secundum badense; Clus. Hist. v. 2. 131. Th. albi supini varietas; Ger. Em. 268. f. 2. Lepidium n. 519; Hall. Hist. v. 1. 223, on the authority of specimens from Davall and Du Cros.)—*Pouch* obovate, abrupt, somewhat heart-shaped, with many seeds. Stem-leaves arrow-shaped. Stems simple. *Style* prominent.—Native of mountainous pastures in Switzerland and England, flowering in June and July. It abounds on limestone rocks, and about lead-mines, in Yorkshire and Derbyshire. Many authors have confounded this

this with the last, from which it differs in having a tufted root, not throwing out scyons, or runners; usually taller and more numerous stems; more glaucous herbage; much smaller flowers, whose petals are erect, and though variable in dimensions, never a quarter so large as in *montanum*; but above all, in having at least three or four seeds in each cell. The pouches moreover are always numerous, and all perfect. Their terminal lobes are variable in length or dilatation, but constantly much shorter than the style. (See the following.) We have often been inclined to remove from this species to the foregoing the synonyms of Bauhin, Clusius, and Gerarde, cited in *Fl. Brit.* on account of the large spreading petals of their figures. But this appears to be an inaccuracy on their part. The habit of their plant; several stems from the simple crown of the root; and the copious pouches in long continued clusters, all properly belong to our *alpestre*, by no means to *montanum*. We have some suspicion that the *alpestre* is rather biennial than perennial. It never remains long in gardens, but that is no proof, nor have we had an opportunity of watching the plant through a season, on its own native hills. Hudson mistook the *perfoliatum*, next described, for *alpestre*.

9. *Th. perfoliatum*. Perfoliate Shepherd's Purse. Linn. Sp. Pl. 902. Willd. n. 11. *Fl. Brit.* n. 4. *Engl. Bot.* t. 2354. Jacq. *Aultr.* t. 337; not. 237, as in Willdenow. (*Th. alterum mitius rotundifolium, burfæ pastoris fructu*; Column. *Ecphr.* 278. t. 276. f. 2. *Th. rotundifolium*; Ger. Em. 266. *Th. cordatum minus, flore albo, infipidum*; Barrel. *ic.* t. 815. *Th. tertium pumilum*; Cluf. *Hist.* v. 2. 131. *Th. minus Clusii*; Ger. Em. 268. *Nasturtium* n. 510; Hall. *Hist.* v. 1. 220. *Pilosella filiquata*; Thal. *Harcyn.* t. 7. f. C. at the end of Camer. *Hort.*)—Pouch exactly inversely heart-shaped. Stem-leaves heart-shaped, sharpest at the base, clasping the branched stem. Style very short.—Native of calcareous pastures or rocks, walls, and dry places, in Switzerland, Germany, France, Italy, Greece, and England, flowering in the spring. In the last-mentioned country it is hardly known any where but in the limestone part of Oxfordshire, about Witney and Burford. We have gathered it at Caserta, near Naples. The root is fibrous and annual. Stem branched from the bottom, except on poor ground, usually from four to six inches high, round, smooth, leafy. Leaves glaucous, smooth, various in size, entire, or now and then slightly toothed; the radical ones stalked, ovate, obtuse; the rest sessile, alternate. Flowers white, small, with narrow, erect petals. Style so short as to be scarcely discernible between the rounded lobes of the pouch. Seeds three or four, at least, in each cell. The small annual root, usually branched stem, and minute style, are quite sufficient to distinguish this species from the last, with which it has been confounded; nor is it difficult, with a moderate degree of observation, to avoid the error of those old botanists, who described its stunted and luxuriant states for distinct species. Ray suspected this, and has adverted to it in his own second edition of the *Synopsis*, by far the most exact, p. 176.

10. *Th. luteum*. Yellow Sicilian Shepherd's Purse. Bivon. Cent. 1. 78. ("Th. *montanum*, glasti folio, parvum, perfoliatum, nonnihil ferratum, filicula cordatâ; Cupan. *Panphyt.* v. 2. t. 256. Th. *montanum luteum*, glasti folio, parvum, perfoliatum, nonnihil ferratum, filiculâ cordiformi; Cupan. *Hort. Cathol.* 212.")—Pouch inversely heart-shaped, nearly orbicular. Leaves toothed, the lowermost stalked; the rest clasping the stem. Style almost equal to the lobes of the seed-vessel.—Native of dry mountainous places near Palermo, flowering in April and May, and sent us by the baron Bivona. This is a small, smooth, glaucous,

annual plant, from one to three inches high. Stem erect, either simple, or branched from the base. Leaves half an inch, more or less, in length; the lower ones spatulate; the others ovate-oblong, bluntish, with a heart-shaped base; all having one or two large teeth at each side. Flowers remarkable for being yellow. They are small, not many together, in short terminal corymbs, becoming elongated clusters of rather large, rounded, reticulated pouches, with a few seeds in each cell. The petals are emarginate, erect, longer than the calyx. Stigma large, on a level with the lobes of the pouch.

11. *Th. Bursa Pastoris*. Common Shepherd's Purse. Linn. Sp. Pl. 903. Willd. n. 13. *Fl. Brit.* n. 6. *Prodr. Fl. Græc.* n. 1499. *Engl. Bot.* t. 1485. *Curt. Lond. fasc. 1. t. 50.* (*Bursa Pastoris*; Ger. Em. 276. Matth. *Valgr.* v. 1. 521.)—Hairy. Pouch inversely heart-shaped, somewhat triangular, scarcely bordered. Radical leaves pinnatifid.—A very common weed in cultivated and waste ground, throughout Europe, as well as in North America, and in most countries where European merchandise or cultivation has reached. We have already mentioned that this species is indubitably the *βλαστis* of Dioscorides. It flowers at all times, from the beginning of spring to the end of autumn. The white tapering annual root is distinguished by a very peculiar nauseous smoke-like scent, when pulled out of the ground. Whole herb rough with starry as well as prominent hairs. Stem various in height, erect, round, with alternate spreading branches, though sometimes so starved as to be quite simple and slender, with all the leaves of the plant undivided; in which state the species is difficult to be recognized. The radical leaves are numerous, close to the ground, variously pinnatifid, mostly toothed, somewhat lyrate, about two or three inches long; the rest linear-oblong, acute, sessile, entire or toothed, embracing the stem with their elongated heart-shaped base. Flowers small, white, in dense corymbs, often tinged with purplish-brown. Pouches smooth, fatchel-shaped, whence the modern name, disposed in very long, lax, upright clusters. Style rather prominent. Seeds numerous, small, oval, a favourite food of small birds, as well as the flower-buds. The flavour of both is warm and pungent.

12. *Th. ceratocarpon*. Horned Shepherd's Purse. Murray in *Comm. Goett.* v. 5. 21. t. 1. Linn. *Suppl.* 295. Willd. n. 14. Ait. n. 3. Scop. *Infub.* v. 1. 10. t. 4.)—Very smooth. Pouch obovate, tumid, with a terminal, double horn-like, compressed border. Leaves lanceolate, somewhat toothed; arrow-shaped at the base.—Native of Siberia, from whence Pallas brought the seeds. The root is annual, tapering. Stem solitary, erect, twelve or eighteen inches high, leafy, mostly quite simple. Leaves all smooth; slightly toothed, or wavy; the radical ones obovate, on long stalks; the rest sessile. Flowers numerous, white, very small. Pouches composing a long cluster, very conspicuous for their two sharp prominent horns, between which stands the very short style. Seeds large, about two in each cell.

THLASPIDIUM, *θλασπίδιον* of Cratevas, according to Tragus; a name whose etymology has been mistaken, like THLASPI, (see that article,) from whence it is manifestly derived. Tournefort, who in his *Institutiones* 214, adopts this name, for what Linnæus more aptly termed *Biscutella*, explains it as meaning that the plants which bore it were allied to *Thlaspi*; and this, no doubt, is correct. But Ambrosini, who considers *Thlaspi* itself as applying to the beaten or flattened form of the seed-vessel, deduces the present word from *θλαω*, to bruise or beat, and *ασπίδιον*, a little shield, which is evidently applicable to the flat shield-like fruit of *Thlaspi arvense*, and is so plausible an explanation, that

that it seems to have chiefly led the modern expounders of ancient writers to take this species for *θλασσις* of Dioscorides. We have already, in its proper place, shewn our Shepherd's Purse to be what he describes; and we can understand the name, as derived from *θλαω*, in no other light, than alluding to the minute seeds, which seem as if beaten to powder. This is by no means the first instance, in which the most apparently just etymology, proves not to be the real one.

THLIBIÆ, in *Antiquity*, a kind of eunuchs. See **THLASIAS** and **CASTRATION**.

THLIPSIS, *θλιψις*, is used, by anatomists, for the compression of any vessel or aperture, by which its cavity is lessened.

THNETOPSYCHITES, composed of *θνηστος*, mortal, and *ψυχη*, soul, in *Ecclesiastical History*; a sect in the ancient church, who believed the soul of man perfectly like that of brutes; and taught that it died with the body. See **SOUL**.

We meet with no account of these heretics any where but in *J. Damascenus Hæref. 90*, unless they be the same with those Eusebius speaks of, *Hiit. Eccles. lib. ix. c. 38*, who relates, that in Origen's time, there were heretics in Arabia, who taught, that the soul of man died with the body; but that it should rise again with it at the end of the world. He adds, that Origen refuted them in a numerous council, and reclaimed them from their errors. *St. Augustine* and *Isidore* call them the Arabian heretics.

Marshall, in his tables, uses the word *Thnetopsychites* instead of *Thnetopsychites*.

THOA, in *Botany*, a Guiana name adopted by *Aublet*, and retained by *Jussieu*, and even *Schreber*; see our article **GNETUM**, to which genus this plant is there, for the first time, referred, as a second species.

THOALABIAN, in *Geography*, a town of Arabia, in the province of *Nedsjed*; 260 miles E.N.E. of *Hajar*.

THOANHOA, a town of *Cochinchina*, at the bottom of a large bay. N. lat. 16° 45'. E. long. 106° 27'.

THOARD, a town of France, in the department of the Lower Alps; 9 miles E.S.E. of *Sisteron*.

THOCO, an island in the Grecian Archipelago, near the coast of Greece, about eight miles in circumference. N. lat. 37° 20'. E. long. 23° 21'.

THOCOS, *θακος*, in *Antiquity*, the same with *Thacas*.

THOGRAI, in *Biography*, a Persian of *Ispahan*, who was grand vizier to the sultan *Malich Mashud*, is celebrated for his poetical talents, a specimen of which is given by *Pococke*; and for a commentary upon the republic of *Plato*, to whom the Saracens paid little attention. After a strange reverse of fortune, *Thograi* was put to death by order of the sultan in the year 1121.

THOIRY, in *Geography*, a town of France, in the department of the *Ain*; 6 miles S.S.W. of *Gex*.

THOKES, in our *Old Writers*, fish with broken bellies, forbid by statute to be mixed or packed with tale-fish. 22 Ed. IV. cap. 2.

THOLEN, in *Geography*. See **TOLEN**.

THOLES, in *Sea Language*, denote small pins driven perpendicularly into the upper edge of a boat. In rowing, the oar passes between the two tholes, in the space called the *row-lock*. Sometimes there is only one pin to each oar, as in the boats navigated on the Mediterranean sea: in that case the oar is hung upon the pin by means of a strop.

THOMÆANS, **THOMEANS**, **THOMITES**, or *Christians of St. Thomas*, a people of the East Indies, in *Cochin*, and upon the coast of *Malabar* and *Coromandel*, who, according to tradition, received the Gospel from the apostle *St. Thomas*.

It appears by the testimony of *Cosmas*, who wrote about

A.D. 547, and whose work is translated by *F. Montfaucon*, that Christianity was established in India in the sixth century. We also find in the subscriptions of the council of *Nice*, that of a prelate, who calls himself bishop of *Persia*. Moreover, an ancient author, cited by *Suidas*, says, that the inhabitants of Interior India, (a name which *Cosmas* gives to the coast of *Malabar*;) the Iberians and Armenians, were baptized under the reign of *Constantine*.

The princes of the country, and particularly *Serant Peroumal*, emperor of *Malabar*, the founder of the city of *Calicut*, A.D. 825, granted extraordinary privileges to these Christians.

When *Vasco de Gama*, the Portuguese admiral, arrived at *Cochin* with a fleet, in the year 1502, these Christians sent deputies to him, imploring his protection, and that of the king his master. The admiral treated them kindly, but was in no condition to afford them any effectual assistance, in relieving them from the yoke of the Pagan kings, to which they were then subject. The language they use in *sacris*, is the Syriac, or, as some say, the Chaldee; but their ordinary language is the same with that of their neighbours. The first missionaries, who attempted to proselyte them to the church of Rome, were *Cordeliers*, but their endeavours proved ineffectual. The distinguishing opinions and religious rites of these Christians are as follow.

They are charged with an invincible attachment to the doctrine of *Nestorius*, and with an obstinate refusal to acknowledge, that the *Virgin* is the mother of God: they have no images in their churches: they believe that the souls of the blessed are not admitted into the presence of God till after the day of universal judgment: they allow only of three sacraments, *viz.* baptism, orders, and the eucharist: they defer the baptism of infants for some time, as for a month, or even for seven, eight, or ten years, after they are born: they make no use of holy oil, neither in baptism, nor in the administration of the other sacraments; but after baptizing their infants, they sprinkle the oil of a species of Indian saffron all over their bodies: they allow of no auricular confession, treat purgatory as a fable, and their priests are permitted to marry: they entertain an extraordinary affection for the Nestorian patriarch of *Babylon*, but will not suffer any mention of the pope, or of the Romish churches in their assemblies. Their days of abstinence are *Wednesday* and *Friday*, and their fast is very severe in *Lent*, during which time they go to church three times a day. They also fast in the same manner during the time of *Advent*. Besides these two greater fasts, which are enjoined on pain of excommunication, they have several others of a religious nature. Their women do not enter a church for forty days after their delivery of a male child, nor for eighty days after the birth of a daughter.

These Christians are in general poorly instructed, knowing only the Lord's prayer and the angelical salutation. Their churches are mean and unadorned buildings, and constructed after the manner of the pagodas. They appear to maintain many of the religious opinions and practices received among Protestants, and reject either wholly, or in a very great measure, those of the church of Rome. They deny the supremacy of the pope, and transubstantiation, and exclude from the number of sacraments, confirmation, extreme unction, and marriage. Such are the errors proscribed by the synod of *Diamper*, held in 1599, by *Aleixo de Meneses*, archbishop of *Goa*, in order to unite the Thomæans to the Romish church. However, notwithstanding the temporary success that attended the vigorous exertions of the archbishop, for which he was recompensed after his return to Europe, with the archbishopric of *Braga*, the viceroyship

of Portugal, and the presidency of the council of state at Madrid, these Christians, oppressed and abused by the Jesuits, relapsed from the church of Rome soon after the death of the archbishop; and notwithstanding the endeavours of Alexander VII. to conciliate them by the mission of four bare-footed Carmelites, they could no more be reduced to submission. At length, when the Dutch took Cochin, in 1663, the Christians of St. Thomas recovered the liberty which they had formerly enjoyed; but they derived little advantage besides from their new masters. Encyclopédie, and Geddes's History of the Church of Malabar and Synod of Diamper, in his Tracts, vol. v. For a further account of this sect, see CHRISTIANS of St. Thomas.

THOMAR, in *Geography*, a town of Portugal, in Estremadura, containing two churches, an hospital, four convents, and about 3600 inhabitants; 63 miles N.E. of Lisbon. N. lat. 39° 34'. W. long. 8° 8'.

THOMAS, furnamed *Didymus*, or the *Twin*, in *Scripture Biography*, one of our Lord's twelve apostles, of whom the evangelist John has given a short account in the 20th chapter of his Gospel. John Chrysostom informs us, that Thomas preached the gospel to the Ethiopians, Parthians, Persians, and Medes, and even, according to tradition, to the Indians, and in the island of Taprobana; and the Christians called after his name in the East, regard him as the founder of their church. See CHRISTIANS of St. Thomas, and THOMEANS.

For an account of the spurious gospel attributed to St. Thomas, we refer to the article GOSPEL.

THOMAS, ANTONY LEONARD, in *Biography*, a distinguished French writer, was born in the diocese of Clermont, in Auvergne, in the year 1732, and designed for the profession of the law; but his attachment to literature induced him to prefer a professorship in the college of Beauvais. His reputation as a man of letters recommended him to the office of confidential secretary to the duke De Praslin, in which he conducted himself with integrity and honour. When he was advised by the duke to become a candidate for a seat in the French Academy, after having five times gained the prize for his compositions, and discovered that he was put forward as a competitor to Marmontel, who was out of favour with persons in power, he refused to be the instrument of such a design. In consequence of this circumstance, the duke dismissed him his office, but procured for him the place of secretary-interpreter for the Swiss Cantons, to which a very inconsiderable salary was annexed; and yet this was the whole benefit which he obtained from court-favour. His career as a writer commenced in 1756, by "Reflections historical and literary on Voltaire's Poem on Natural Religion;" and on all subsequent occasions he proved himself the friend of virtue, and a lover of mankind. His eulogies, particularly those on Des Cartes and Marcus Aurelius, were highly commended. His "Essai sur les Caractères, les Mœurs, et l'Esprit des Femmes," 1772, is a sprightly performance, in which fine writing and philosophical observation are combined. His "Essai sur les Eloges," in 2 vols. 1775, exhibits striking portraits with just ideas. As a poet, he appears to advantage in his "Épître au Peuple," his "Ode sur les Temps," and his "Poème de Jumonville." His epic poem, entitled "Le Pétreide," the hero of which was czar Peter, was left unfinished. He was distinguished by his singularities, and also by his sympathy with persons in distress, for whose relief he submitted to personal inconvenience and privation. His death took place at the seat of the archbishop of Lyons, in September 1785, at the age of 53. His works, in prose and verse, were published at Paris, in 7 vols. 8vo. Gen. Biog.

THOMAS, CHRISTIAN, an Eclectic philosopher of the

German schools, who deserves notice on account of the boldness with which he threw off the yoke of human authority, and the perseverance with which, against much opposition, and in many vicissitudes of fortune, he maintained and exercised the right of free inquiry. He was born at Leipzig in the year 1655, and finished his course of education in the university of his native city. Upon a perusal of Puffendorf's Apology for rejecting the scholastic principles of morals and law, he renounced implicit deference to all ancient dogmas; and engaged in reading lectures on the subject of natural law, first from the text of Grotius, and afterwards from that of Puffendorf, in the full exercise of his own judgment, with prudent caution while his father lived, but after his death, with a boldness which incurred the violent resentment of theologians and professors. In 1687 he published an "Introduction to Puffendorf," in which he deduced the obligation of morality from natural principles, and thus gave great offence. In the following year he became still more unpopular, by commencing a monthly literary journal, entitled "Free Thoughts; or, Monthly Dialogues on various Books, chiefly new," containing a severe attack upon many of his contemporaries. Complaints of the raillery of this satirical work were lodged before the ecclesiastical court of Dresden; and Thomas with difficulty escaped punishment. Some other sarcastical pieces inflamed the resentment of his enemies, and he was charged before the same court by the clergy of Leipzig with a contempt of religion. Soon after he published another satirical work "On the Divine Right of Kings," "A Defence of the Sect of the Pietists," and some other eccentric works of the same general character, for which he was threatened with imprisonment; but obtaining permission from the elector of Brandenburg to retire, he became a voluntary exile from Leipzig: and soon after was appointed public professor of jurisprudence, first in Berlin, and afterwards at Halle. In these situations he indulged his satirical humour, and his inclination for controversy, as long as he lived; persevering in his endeavours to correct and subdue the prejudices of mankind, and to improve the state of philosophy. He died at Halle, in the year 1728. Thomas was the author of several treatises on logic, morals, and jurisprudence, in which he deviates from opinions generally received; and his latter publications are, in many respects, inconsistent with the former. His principal philosophical works are, "An Introduction to Aulic Philosophy; or Outlines of the Art of Thinking and Reasoning," Leips. 1688; "Introduction to Rational Philosophy;" "A Logical Praxis," Hal. 1691; "Introduction to Moral Philosophy," 1692; "A Cure for irregular Passions, and the Doctrine of Self-knowledge," 1696; "The new Art of discovering the secret Thoughts of Men;" "Divine Jurisprudence;" "Foundations of the Law of Nature and Nations;" "Dissertation on the Crime of Magic;" "Essay on the Nature and Essence of Spirit, or Principles of Natural and Moral Science," 1699; and "History of Wisdom and Folly."

As a specimen of the peculiar tenets and maxims of this eccentric philosopher, we shall subjoin the following.

"Thought arises from images impressed upon the brain; and the action of thinking is performed in the whole brain. Brutes are destitute of sensation. Man is a corporeal substance, capable of thinking and moving, or endued with intellect and will. Man does not always think. Truth is the agreement of thought with the nature of things. The senses are not deceitful, but all fallacy is the effect of precipitation and prejudice. From perceptions arise ideas, and their relations; and from these, reasonings. It is impossible

to discover truth by the syllogistic art. No other rule is necessary in reasoning, than that of following the natural order of investigation; beginning from those things which are best known; and proceeding, by easy steps, to those which are more difficult.

“Perception is a passive affection, produced by some external object, either in the intellectual sense, or in the inclination of the will. Essence is that without which a thing cannot be perceived. God is not perceived by the intellectual sense, but by the inclination of the will: for creatures affect the brain; but God, the heart. All creatures are in God: nothing is exterior to him. Creation is extension produced from nothing by the divine power. Creatures are of two kinds, passive and active; the former is matter; the latter, spirit. Matter is dark and cold, and capable of being acted upon by spirit, which is light, warm, and active. Spirit may subsist without matter, but desires a union with it. All bodies consist of matter and spirit, and have therefore some kind of life. Spirit attracts spirit, and thus sensibly operates upon matter united to spirit. This attraction in man is called love; in other bodies, sympathy. A finite spirit may be considered as a limited sphere in which rays, luminous, warm, and active, flow from a centre. Spirit is the region of the body to which it is united. The region of finite spirits is God. The human soul is a ray from the divine nature; whence it desires union with God, who is love. Since the essence of spirit consists in action, and of body in passion, spirit may exist without thought: of this kind are light, ether, and other active principles in nature.

“Good consists in the harmony of other things with man and his several powers. The highest felicity of man consists in tranquil delight. The fountain of this delight is the rational love of man and of God. Internal love and reverence are all the homage which nature teaches us to pay to God. With respect to God, the two capital errors are atheism and superstition. Superstition is worse than atheism. The love of God is a supernatural affection, which prepares the soul for future felicity. The rational love of man comprehends all social virtues. Rational self-love includes self-preservation, temperance, purity, industry, fortitude. To wise men, virtue is its own reward. Laws are appointed for the sake of fools, to conduct them to internal tranquillity, and external peace. Of fools, there are three classes; those who disturb external peace; those who do nothing to promote it; and those who do not enjoy internal peace. The first have need of authority; the second of authority and counsel; the third of counsel alone. The obligation of authority and law extends only to external actions, which are just when they are conformable to law: justice is therefore to be distinguished from virtue, which respects the internal man, and requires a conformity to the law of nature.” Brucker by Enfield, vol. ii.

THOMAS. *Christians of St. Thomas.* See THOMÉANS.

THOMAS'S *Hospital.* See HOSPITAL.

THOMAS, *St.*, in *Geography*, an island of the Atlantic, near the coast of Guinea, situated on the equinoctial line, of a circular form, about ten leagues in circumference, discovered by the Portuguese in the year 1640. The climate is insalubrious, and at some seasons of the year the sky is even darkened by thick fogs, which are dispersed by the winds that blow in the months of July and August. In this island the inhabitants have two winters, like those of other places that are under the same parallel, but without the cold that distinguishes that season in Europe. The rains continue from December to February; and spring begins with our summer, in the month of May. During the first three months of this period, the

heat is insupportable, and the first settlers gradually inured themselves to the climate. The soil on this island is viscous and clayey, and mixed with chalk; but it is rendered fertile by the heavy night dews. The plants and shrubs, which it rapidly produces, are burnt to ashes, and applied as the most beneficial manure to sugar-canes; which were first planted here by the Portuguese: in their endeavours to cultivate which they have been disappointed. Rice and millet succeed, and vines of the richest kind, as well as melons, cucumbers, figs, ginger, and all sorts of roots, pulse, and pot-herbs, are cheaply reared, and they arrive at the utmost perfection. Yams are in this island a very wholesome and delicious diet. The land of this island is well watered, and much fertilized by its rivers and streams. In the centre is a high mountain, covered with wood and fruit-trees, whose summit is nevertheless always covered with snow. Its quadrupeds, birds, and fishes, are very various, and abundant; and St. Thomas would be equal to any spot in the globe, if its temperature corresponded to its other qualities. The inhabitants are the descendants of the Portuguese first settlers and the negroes, who are retained in the service of Europeans, and such as prefer a residence here to Angola. They are for the most part Roman Catholics, and extremely ignorant, superstitious, and bigotted. The ecclesiastical government is under the direction of the bishop, who is a suffragan of the archbishop of Lisbon. E. long. 8° 6'.—Also, a town of Hindoostan, on the coast of Coromandel. Here was formerly a powerful city, called “Meliapour,” or “Meilabour,” the capital of the kingdom of Coromandel; but on the ruins of this city the Portuguese erected the stately city of St. Thomas. This is inhabited chiefly by weavers and dyers, who manufacture the best coloured stuffs in India. The Portuguese, who rebuilt this place in 1545, have raised it from a state of desolation to a flourishing state, both with regard to its buildings and inhabitants. Whilst the Portuguese retained it, it was a bishopric under the archbishop of Goa; and they had several churches, besides monasteries, and a college for the instruction of the Portuguese and Malabar children. Here is also the famous church of St. Thomas the Apostle, where it is pretended that he was buried. (See THOMÉANS, and CHRISTIANS of *St. Thomas.*) The city had seven gates, and was, on account of its situation, guarded by the sea on one side, and a chain of mountains on the other, very strong: nevertheless it was taken by the Moors after a long siege, and retained in their possession.—Also, a town of Germany, in the archduchy of Austria; 6 miles N.W. of Grejn.—Also, a town of Savoy, in the county of Maurienne; 3 miles N. of Montier.—Also, the principal of the Virgin Islands, in the West Indies, about six leagues in circumference, belonging to the Danes. It abounds with potatoes, millet, manioc, and most sorts of fruits and herbage, and especially sugar and tobacco, but is much exposed to the attacks of mosquitos and other vermin. The English had formerly a spacious settlement in this island; and here is a safe and commodious harbour, with two natural mounds upon it, fitted for the reception of two batteries to guard its entrance. Nearly in the centre of the harbour is a small fort; and about 50 or 60 paces W. of it is the town, consisting chiefly of one long street, at the end of which is the Danish factory, with convenient warehouses. On the right side of this factory is the Brandenburg quarter, containing two small streets, full of French refugees from Europe and the islands. Most of the houses are built of brick, and one story high. The trade of this small island is considerable, particularly in time of peace; as it is the staple for such articles of traffic as the French, English, Dutch, and Spaniards are not allowed to deal in publicly in their own islands; and

in war, their privateers bring their prizes hither for sale. N. lat. $18^{\circ} 22'$. W. long. $64^{\circ} 50'$.—Also, the capital of Spanish Guiana, called “San Tomé,” which is situated at the foot of a small mountain on the right bank of the Oronoko. For its defence, a fort is placed opposite to the city and on the left bank of the river; it is surrounded by a number of houses, dependent, like the fort, on the province of Guiana. They call this place Port Raphael; and it is here the communication between Guiana and the provinces of Venezuela and Comana is found. Between Port Raphael and the city is seen the island called “Del Medio,” or the Middle, because it is in the middle of the river. It is a rock, which, in its southern part, discovers itself in summer, and is under water in floods. The principal channel is between the city and this island: when the water is low it has 200 feet, and on the increase of the river 50 or 60 more.—Also, a town of the United States of America, in South Carolina; 21 miles N. of Charlestown.—Also, a town of the island of Cuba; 130 miles W.S.W. of Havannah.

THOMAS *de Castile, St.*, a town of North America, in the government of Mexico, and province of Guatemala.

THOMAS'S Bay, a bay on the W. coast of Antigua.

THOMAS'S Creek, a river of South Carolina, which runs into the Great Pedee.

THOMAS'S Gulf, *St.*, a bay of the Atlantic, on the W. coast of Africa. S. lat. $24^{\circ} 50'$.

THOMAS'S Head, *St.*, a cape of England, on the N.W. coast of the county of Somerset, at the mouth of the Severn. N. lat. $51^{\circ} 20'$. W. long. $73^{\circ} 35'$.

THOMAS'S Hospital. See HOSPITAL.

THOMASBRUCK, in *Geography*. See THAMSBRUCK.

THOMASIUS, JACOBUS, in *Biography*, a writer in history and philosophy, professor of eloquence in the university of Leipzig, and chiefly distinguished as the preceptor of the illustrious Leibnitz, was born at Leipzig in the year 1622. Having obtained distinction by his lectures and public theses in his native city, he was advanced to the office of co-rector, first of the college of St. Nicholas, and afterwards of that of St. Thomas. His erudition was extensive, nor was he less distinguished by his modesty and by his disinclination to controversy. Among his numerous works, the principal are “Antiquities of Philosophical and Ecclesiastical History;” “Dissertations on the Stoical Philosophy;” and on other Subjects relating to the History of Philosophy;” and “A Dissertation on Literary Plagiarism, with a List of 100 Plagiarists,” all in Latin. He died in the year 1684. Brucker. Moreri.

THOMASIUS, CHRISTIAN, son of the preceding, an eminent jurist, was born at Leipzig in 1655. Having studied the law at Francfort on the Oder, he was made a doctor in that faculty in 1679; and returning to his native city, he attended the bar, and wrote some treatises on the law. He was the friend of Puffendorf. By opposing the scholastic philosophy in a German journal, commenced in 1688, he excited opposition, and raised against himself many enemies. Many circumstances occurred which increased the number of his adversaries, and at length he was denounced to the court of Dresden as a heretic and Calvinist. The dread of persecution induced him to withdraw to Berlin, and the king of Prussia offered him an asylum at Halle, where he intended to found an university. In this institution he occupied the second chair of law, and on the death of Stryckius, in 1710, he was advanced to the first chair. In 1713 he defended concubinage, and being denounced for this opinion by the theological faculty of Halle, orders were issued for proceeding against him criminally. But upon the examination of his

theses, by commissioners, the proceedings against him were stopped. The dispute, however, continued; nevertheless he rose to the post of privy-counsellor to the king, and director of the university of Halle, and died in 1728. Mosheim has given this character of Thomafius. “His views were vast; he aimed at the reformation of philosophy in general, and of the Peripatetic system in particular; and he assiduously employed both the power of exhortation and the influence of example, in order to persuade the Saxons to reject the Aristotelian system, which he had never read, and which most certainly he did not understand. The scheme of philosophy which he substituted in its place was received with little applause, and soon sunk into oblivion; but his attempt to overturn the system of the Peripatetics, and to restore the freedom of philosophical inquiry, was attended with remarkable success, made in a little time the most rapid progress, and produced such admirable effects, that Thomafius is looked upon, to this day, as the chief of those bold spirits who pulled down philosophical tyranny from its throne in Germany, and gave a mortal blow to what was called the Sectarian philosophy in that country.” Mosheim’s *Ecl. Hist.* Moreri.

THOMASSIN, LOUIS, an ecclesiastical writer, was born at Aix, in Provence, in 1619, and was admitted into the congregation of the Oratory in the fourteenth year of his age. He afterwards became professor of theology at Saumur, and laying aside scholastic subtleties, adopted the method of teaching by the scriptures, fathers, and councils: and in 1654 he was called to the seminary of St. Magloire at Paris. His “Latin Dissertations on the Councils,” were published by the desire of the archbishop of Paris, of which the first and only volume appeared in 1667, 4to. In the following year he published “Memoires sur la Grace,” 3 vols, 8vo., in which work he attempts to conciliate the Greek fathers with St. Augustine. This was reprinted in 1682, with the addition of two memoirs. In 1678 he published the first volume of a work, entitled “De la Discipline Ecclesiastique,” which was followed by a second volume in 1679, and a third in 1681. This work was translated into Latin, in 3 vols. fol. from respect to pope Innocent XI. and for the advantage of more unlimited circulation. His other works, which we can merely enumerate, were “Dogmata Theologica,” 3 vols. 1680–89; “The Discipline of the Church and Christian Morality;” “On the Divine Service;” “On Festivals;” “On Fasts;” “On Truth and Falshood;” “On the Unity of the Church;” “On Alms, Trade, and Usury;” “Methode d’enseigner chretienement la Grammaire, ou les Langues par rapport a l’Ecriture Sainte,” 2 vols. 8vo.; and “Glossaire universelle Hebraique,” which latter appeared after his death in 1697, folio.

Thomassin died in the year 1695, having for some time enjoyed a pension of 1000 livres granted to him by the French clergy, and of which he gave one half to the poor. One of his biographers characterises him as “humble, modest, and mild, fond of study and retirement, and shunning disputes.”—Although his reading was extensive, his erudition was not of the highest class, and it is said that his work on Discipline contains many mistakes where Greek authors are cited. Moreri. *Gen. Biog.*

THOMASTOWN, in *Geography*, a post-town of the county of Kilkenny, Ireland, situate on the river Nore, over which it has a fine bridge. The castle was built about 1180, by Thomas Fitzanthonny, from whom the town takes its Irish name of *Bally-mac-Andan*; i. e. town of Anthony. It was a borough, and sent two members to parliament, but lost that privilege by the Union. The Nore is navigable to this town

for small vessels. It is 59 miles S.S.W. from Dublin, and 15½ N. from Waterford.

THOMASTOWN, a post-town of the United States, in the district of Maine, and county of Lincoln, containing 2100 inhabitants.

THOMISM, or THOMAISM, the doctrine of St. Thomas Aquinas, and his followers the Thomists, chiefly with regard to predestination and grace. See his biographical article.

There is some doubt what the true, genuine Thomism is: the Dominicans pretend to hold pure Thomism; but there are other authors who distinguish the Thomism of St. Thomas from that of the Dominicans.

Others, again, make Thomism no other than a kind of Jansenism disguised; but Jansenism, we know, has been condemned by the popes, which pure Thomism never was.

In effect, the writings of Alvarez and Lemos, who were appointed, by their order, to lay down and defend before the holy see, the dogmata of their school, have since been reputed the rule of pure Thomism.

Those two authors distinguish four classes of Thomists: the first, which they reject, destroys or takes away liberty; the second and third do not differ from Molina. The last, which Alvarez embraces, admits a physical premotion, or predetermination, which is a complement of the active power, by which it passes from the first act to the second; that is, from complete and next power to action.

This premotion, they hold, is offered in sufficient grace: sufficient grace is given to all men; and that they have a complete, independent, next power not to act, and even to reject the most efficacious grace.

THOMISTS, a sect of school divines, who maintain Thomism.

The avowed antagonists of the Thomists are the Scotists.

THOMITES. See THOMEANS.

THOMMDAMM, in *Geography*, a town of the duchy of Saxe Lauenburg, on the Elbe; 25 miles S.E. of Lauenburg.

THOMPSON, Sir BENJAMIN, *Count of Rumford*, in *Biography*, distinguished by his assiduity and zeal in the promotion of science, and in devising and executing schemes of public utility, was born at the village of Rumford, in New England, in the year 1752; and with the assistance afforded him by a professor of natural philosophy in the American university of Cambridge, acquired in early life such a degree of knowledge as enabled him to give instruction to others. By an advantageous marriage, while he was young, his advancement was accelerated, so that he obtained the rank of a major in the militia of his native district. When the war broke out between the mother-country and her colonies, he took part with the former, and by means of his local knowledge, he rendered himself useful to the British generals in America. In process of time he repaired to England, and recommending himself to lord George Germaine, the chief minister in the American department, he obtained a place in his office. Towards the close of the war, the same nobleman, with a view of securing for him a permanent provision, sent him to New York, where he raised a regiment of dragoons, and by being appointed lieutenant-colonel, became entitled to half-pay. Upon his return to England, his majesty, in 1784, conferred upon him the honour of knighthood; and for some time he occupied the post of one of the under-secretaries of state. Soon after he made a tour to the continent, and being warmly recommended by the prince of Deux-Ponts, afterward king of Bavaria, to his relation the reigning elector-palatine, and duke of Bavaria, he was admitted into his service, and occupied an eminent station. He had thus an opportunity of effecting many important and

useful reforms in the departments of the state, both civil and military. His attention was at this time particularly directed to the suppression of mendicity, which prevailed not only at Munich, the capital, but through the whole country, to an extent that rendered the restraint and abolition of it a very difficult and hazardous undertaking. With this view he formed a plan for employing all mendicants; and having provided a building for their reception, and materials for their labour, he sallied forth into the streets of the city on the 1st of January 1790 (New-year's day being set apart for giving alms in Bavaria), accompanied by the field-officers of the garrison and the magistrates of the city; and arresting with his own hand the first beggar that came in his way, his attendants followed his example, so that before night not a single beggar was to be seen in the whole metropolis. Those that were arrested were conducted to the town-hall, where their names were inscribed, and then ordered to repair to the work-house, where they would find employment, and a sufficiency of wholesome food. In consequence of these prompt and vigorous measures, the evil was redressed, and the mendicants were led by habit to prefer industry to idleness, and decency to the filth, rags, and squalid wretchedness attendant on beggary. He also introduced into Bavaria the culture and use of potatoes. For all these services sir Benjamin was decorated by the Bavarian sovereign with several orders, promoted to the rank of lieutenant-general, and created a count by the title of his native place, Rumford. During his abode at Munich, he commenced his experiments upon the improvement of fire-places, with respect to the economy of fuel, and the convenience of cooking; and also his plans for a cheaper and more nutritive mode of feeding the poor, which gave him peculiar celebrity. Having quitted Bavaria in 1799, he resided for some time in this country, pursuing a variety of experiments on the nature and application of heat, and the construction of chimneys, grates, and fire-places. He also promoted science both by his own researches and experiments, and by liberally exciting emulation in others, upon a more enlarged plan. For the latter purpose, he transferred, on an occasional visit to this country in 1796, to the Royal Society of London, of which he was a member, 1000*l.* 3*per cent.* stock, the interest of which was to be applied every second year as a premium to the author of the most important discovery on the subjects of heat and light in any part of Europe during the two preceding years; the preference to be always given to such discoveries as, in the opinion of the president and council, tend most to the benefit of mankind; which indeed was the leading object of all his researches. He also suggested the plan, and assisted in the formation of the Royal Institution, which has produced several other establishments of a similar nature.

In the year 1802 he left England for Paris, which became his fixed residence, and where he married the widow of the celebrated chemist, Lavoisier; but this connection proving unhappy, it was soon terminated by a separation. The count afterwards retired to a country-house at Auteuil, about four miles from Paris, which he rendered a delightful habitation. Besides the improvement of his grounds, in which he took great pleasure, he pursued a variety of philosophical and mechanical researches. With his superior talents he combined certain peculiarities, and a tenaciousness, not to call it obstinacy, of temper, which prevented his enjoying the pleasures of social intercourse. Although he disapproved both the character and politics of the French, he preferred their climate to every other; and he obtained permission from the king of Bavaria to continue in France, and to enjoy his pension of 1200*l.* a-year. He lived in a state of retirement, and also in a course of abstemiousness,

which debilitated his constitution, and rendered it incapable of resisting an attack of low fever, by which he was carried off in August 1814, in his 63d year. By his first wife he had one daughter, now resident at Boston.

Although count Rumford was not a learned man, he acquired by his knowledge of the French and German languages, and by his extensive acquaintance, and frequent conversation with literary men, a large stock of literature and science. His peculiar talent was that of contriving instruments, and devising experiments for facilitating his researches in those branches of economics and scientific philosophy to which his attention was directed. He was also distinguished by a steadiness and perseverance of pursuit, which were favourable to his attainment of the objects which he had in view. As to his person, his stature was above the middle size, his countenance was dignified and pleasing, and his manner and tone of voice mild and gentle. He was, nevertheless, ambitious of distinction, and too prone to dictate in transactions with regard to which other persons were jointly concerned with himself. The papers which he communicated both to the Royal Society and French Institute, and which are published in their Transactions and Memoirs, are numerous. The only separate publication of count Rumford was a series of "Essays, Experimental, Political, Economical, and Philosophical," commencing with the year 1796, and continued to 18 in number, and occupying 4 vols. 8vo. Gent. Mag. for October 1814.

THOMPSON, in *Geography*, a town of America, in the state of New York, the capital of Sullivan county; bounded N. by Wawarsing and Neverfink, E. by Mamakating, S. by Deerpark in Orange county, and W. by the Mongaup, which separates it from Lumberland, Bethel, and Liberty. Its length N. and S. is about 34 miles, and breadth 12. The principal settlements are Thompson, Monticello, Bridgeville, and Concord. The whole area of Thompson is 139,500 acres; and the population by the census of 1810, consisted of 1290 persons. The principal streams are the Neverfink, Mongaup, and Sheldrake.—Also, a township of Connecticut, in the county of Windham; 20 miles N.N.E. of Windham: the place contains 2467 inhabitants.

THOMPSON'S Creek, a river of South Carolina, which runs into the Atlantic, N. lat. 34° 44'. W. long. 79° 46'.—Also, a river of West Florida, which runs into the Mississippi, N. lat. 30° 59'. W. long. 91° 30'.

THOMPSON'S Harbour, a harbour in Hudson's Bay. N. lat. 60° 20'. W. long. 78°.

THOMPSON'S Island, a small island of Upper Canada, at the entrance of the river St. Claire.

THOMPSONSBOROUGH, a town of America, in the district of Maine; 30 miles N.E. of Portland.

THOMSI, a town of Hungary; 11 miles S.W. of Canischa.

THOMSON, JAMES, in *Biography*, a popular English poet, was born at Ednam, near Kelso, in Scotland, in the year 1700, being one of the nine children of the minister of that place. Whilst he was at school at Jedburgh, he manifested no powers superior to those of other boys, except in a taste for poetry, which he betimes indulged, and which introduced him, during his vacations, to the society of some neighbouring gentlemen. Of his productions, however, he thought so humbly, that on New-year's day he committed to the flames those of each preceding year. From Jedburgh he was removed to the university of Edinburgh, where he persevered in the cultivation and exercise of his poetical talents; but upon the death of his father, he complied with the wishes of his friends by entering on a course of divinity. His probationary exercise was the explanation

of a psalm, which was written in a style so splendid, as to incur reproof from the theological professor, as being altogether unsuitable to the audience which might probably attend his future ministry. Having no great inclination for the office, this admonition induced him to devote himself entirely to poetry: and after spending some time as private tutor in the family of lord Binning, he determined, at the suggestion of a lady, who was his mother's friend, to try his fortune in London. In 1725 he came to London, and meeting with his college acquaintance Mallet, he shewed him his poem of "Winter," in an imperfect state; who advised him to finish and publish it. Mr. Millar, a well-known London bookseller, bought it for a small sum, and published it in 1726. At first it attracted little attention; but Mr. Whateley, a gentleman of acknowledged taste, giving a favourable account of it, brought the poem and its author into notice. The author was introduced to Pope, and recommended by bishop Rundle to lord chancellor Talbot. In 1727 he published his "Summer," and in the same year "A Poem sacred to the Memory of Sir Isaac Newton," just deceased, and also his "Britannia." His "Spring" was published in 1728; and in 1730 the Seasons were completed by "Autumn," and published collectively. In 1728 Thomson, aspiring to the popularity and emolument of dramatic composition, succeeded in introducing upon the stage of Drury-lane his tragedy of "Sophoniba." Its reception, however, was not very flattering. Soon after he was appointed, by the recommendation of Dr. Rundle, travelling companion to the Hon. Mr. Talbot, the eldest son of the chancellor, and had an opportunity of visiting most of the courts and countries of the European continent. During this tour, the idea of his poem on "Liberty" was suggested to him, and he employed two years in completing it. In consequence of this excursion, he obtained, by the interest of Mr. Talbot, the place of secretary of the briefs, which, being almost a sinecure, afforded him leisure for his private literary pursuits. His poem on "Liberty" was more coolly received than the nature of the subject led him to expect. When lord Hardwick succeeded the lord chancellor Talbot, Thomson lost his place; but upon being questioned by the prince of Wales, to whom he was introduced, by Mr. (afterwards lord) Lyttelton, as to his circumstances, a pension of 100*l.* a year was granted to him.

Upon the introduction of his second tragedy, "Agamemnon," to Drury-lane, in 1738, he was so anxious concerning its success, that he is said to have been thrown into a copious perspiration. His "Edward and Eleonora" was prevented from appearing by the interference of the lord chamberlain. The "Masque of Alfred," performed before the prince at Cliefden-house, in 1740, was the joint production of himself and Mallet; and in this piece was introduced the famous song of "Rule Britannia," the production of one or other of these two persons. The most successful of Thomson's dramatic pieces was his "Tancred and Sigismunda," which appeared at Drury-lane in 1745; but his "crowning performance," as one of his biographers calls it, was "The Castle of Indolence," published in 1746. Our poet was now rendered independent by the interest of Mr. Lyttelton, who obtained for him the office of surveyor-general of the Leeward islands, which, after payment of a deputy, yielded him about 300*l.* a year. Death, however, in consequence of a fever occasioned by a cold, deprived him, in August 1748, of the comparative affluence derived from this appointment. His remains were interred in Richmond church, without any memorial; but in 1762 a monument was erected in Westminster Abbey, the expence of which was defrayed out of the profits of an edition of his works, published by

Mr. Millar. His "Coriolanus" was brought on the stage by his executors, in 1749, for the benefit of the surviving branches of his family. The prologue, composed by Lyttelton, was very feelingly delivered by Quin, the intimate friend of Thomson.

Thomson's person was large and awkward, and his countenance unanimated; nor did his appearance or manners indicate genius or refinement. With select friends, however, he was easy and cheerful, and universally beloved for the kindness of his heart, and freedom from those passions that sometimes disgrace men of literary character. He was indolent and self-indulgent in his habits; although "no poet," as his biographer says, "has deserved more praise for the moral tenor of his writings. Unbounded philanthropy, enlarged ideas of the dignity of man, and of his rights, love of virtue, public and private, and a devotional spirit, narrowed by no views of sect or party, give soul to his verse when not merely descriptive; but no one can rise from the perusal of his pages without melioration of his principles or feelings." His poetical merit is most conspicuous in his "Seasons," and though Dr. Johnson charges it with a defect of method, yet as a history of the year through its changes, depending upon the vicissitude of the seasons, it adheres sufficiently to its general plan for preserving a continuity of subject, with due allowances for the moral and philosophical digressions by which it is varied. Its diction, though somewhat laboured, is energetic and expressive. Its verification, though it does not indicate a nice ear, is seldom unpleasantly harsh. Upon the whole, continues the biographer now cited, "scarcely any poem has been more, and more deservedly, popular; and it has exerted a powerful influence upon public taste, not only in this country, but throughout Europe. Thomson's other pieces in blank verse display a vivid imagination, a comprehensive understanding, and exalted sentiments, but are not marked with any peculiar character. The addition to his fame as a poet has principally arisen from his "Castle of Indolence," an allegorical composition in the manner of Spenser." Of his tragedies, the best that can be said is that they maintain a respectable rank among the productions of the modern school of the drama, which, when they disappear from the stage, are seldom taken up in the closet. Murdoch's *Life of Thomson*. Johnson's *Lives of the Poets*. Gen. Biog.

THONE, in *Geography*. See TONE.

THONE, in *Agriculture*, a term signifying somewhat damp and cold, not thoroughly dry. Also flaxid or limber, as undried hay, corn, or straw in a moist state.

THONGTONG, in *Geography*, a town of the Birman empire; 10 miles N.W. of Raynaangong.

THONNA, a town of Saxony, in the principality of Gotha; 12 miles from Gotha.

THONNAUSTAUFF, a town of Bavaria, near the Danube; 3 miles from Ratibon.

THONNES, or THONNEX, a town of France, in the department of the Lemane; 9 miles S.E. of Annecy.

THONON, or TONON, a town of France, in the department of the Lemane, late capital of the duchy of Chablais, on the lake of Geneva, situated on a plain a little elevated. It is not environed with walls, but was formerly defended by a strong castle, surrounded with lofty towers, where Amadeus VIII. and IX. and Louis, dukes of Savoy, resided for some time. The castle was burned and demolished, in the 16th century, by the Bernois. It has one parish church and several convents; 18 miles N.E. of Geneva. N. lat. 46° 18'. E. long. 6° 32'.

THOPH. See MACHUL and SISTRUM.

THOPHAIL, ABU GIAFAR, in *Biography*, a cele-

brated Peripatetic philosopher and physician, was a native of Seville in Spain, and preceptor to Maimonides and Averröes. This philosopher employed the Aristotelian doctrine to the purposes of enthusiasm, in the elegant tale still extant of "Hai Ebr Yockdan;" a youth who, having been exposed when an infant on the sea-coast, was nourished by a hind, and grew up in the woods, without any intercourse with human beings; and who, by the unaided exertions of his own powers, attained to the knowledge of things natural and supernatural, and arrived at the felicity of an intuitive intercourse with the divine mind. This piece is written with such elegance of language and vigour of imagination, that, notwithstanding the improbability of the story, it has been universally admired. It exhibits a favourable specimen of Peripatetic philosophy, as it was taught among the Saracens; and, at the same time, affords a memorable example of the unnatural alliance, which was now so generally established between philosophy and fanaticism. This work was translated by Edward Pococke, jun. from the Arabic into Latin, under the title of "Philosophus Autodidactus," and printed in 4to. at Oxford, in 1700. It was also translated into English by S. Hoadley, professor of Arabic in Cambridge, ed. Lond. 1711, 8vo., and also into Dutch. Thophaïl is said to have written several other works, and died at Seville in 1175. Brucker by Enfield. Gen. Biog.

THOR, in *Mythology*, a deity worshipped by the ancient inhabitants of the northern nations; particularly by the ancient Scandinavians and Celts. Julius Cæsar (Com. lib. vi. c. 17.) speaks of a god of the Gauls, who was charged with the conduct of the atmosphere, and presided over the winds and tempests, under the name of Jupiter: but Lucan gives him a name, which bears a greater resemblance to that of Thor, viz. *Taranis*, a word which, to this day, in the Welsh language, signifies *thunder*. The authority of this deity extended over the winds and seasons, and particularly over thunder and lightning. In the system of the primitive religion, the god Thor was probably one of those genii, or subaltern deities, sprung from the union of Odin, or the Supreme Being, and the Earth. The Edda calls him the most valiant of the sons of Odin; and in the Icelandic mythology, he is considered as the defender and avenger of the gods. He always carried a mace, or club, which as often as he discharged it returned to his hand of itself; he grasped it with gauntlets of iron, and was possessed of a girdle which had the virtue to renew his strength as often as was needful. With these formidable arms he overthrew the monsters and giants, when the gods sent him to oppose their enemies. Thor, Friga, or Freya, and Odin, composed the court or supreme council of the gods, and were the principal objects of the worship and veneration of all the Scandinavians. The Danes seem to have paid the highest honour to Odin. The inhabitants of Norway and Iceland appear to have been under the immediate protection of Thor: and the Swedes chose for their tutelary deity Freya, or Frey, an inferior divinity, who, according to the Edda, presided over the seasons of the year, and bestowed peace, fertility, and riches.

There was a day consecrated to Thor, which still retains his name in the Danish, Swedish, English, and Low Dutch languages, viz. *Thursday*. This word has been rendered into Latin by *dies Jovis*, or *Jupiter's day*; for this deity, according to the ideas of the Romans, was the god of thunder. Mallet's North. Ant. vol. i. p. 95.

THOR, *Le*, in *Geography*, a town of France, in the department of the Mouths of the Rhone; 9 miles E. of Avignon.

THORA, a town of Hindoostan, in the circar of Rantampour; 45 miles S. of Rantampour.

THORA,

THORA, in *Botany*. See ACONITUM.

THORACIC, in *Anatomy*, an epithet applied to various parts in and about the chest, as to the aorta above the diaphragm, and to some branches of the axillary artery (see ARTERY); to some branches of the axillary plexus of nerves (see NERVE); to the trunk of the absorbing system of vessels. See ABSORBENTS.

THORACICI, in the *Linnæan System of Ichthyology*, the name of the third order of bony fishes, respiring by means of gills only: the character of which is, that the bronchia are ossiculated, and the ventral fins are placed underneath the thorax. This order in Gmelin's edition of the Linnæan system, includes nineteen genera, and a good number of species. The genera are, the *cepola*, *echencis*, *coryphæna*, *gobius*, *cottus*, *scorpena*, *zeus*, *pleuronectes*, *chatodon*, *sparus*, *scarus*, *labrus*, *sciæna*, *perca*, *gasterosteus*, *scomber*, *centrogaster*, *nullus*, and *trigla*.

THORÆ RADIX, in the *Materia Medica*, the name of a root which keeps its place in the catalogues of officinal simples, but is seldom used. See ACONITUM and ANTHORA.

The plant which produces it is the *thora valdensis* of Gerarde. It is kept in the gardens of the curious, but grows wild in the mountainous parts of Germany. The root is composed of a number of granules or small lumps, like that of the common ranunculus; the leaves are roundish, and stand on small pedicles, and the stalks are about six inches high, and the flowers yellow, and like those of our common wild ranunculuses.

The root is acrid and corrosive, and the juice of the leaves is said to poison animals, and to have been used by the ancients for that purpose.

THORAME, in *Geography*, a town of France, in the department of the Lower Alps; 13 miles E. of Digne.

THORAX, in *Anatomy*, that division of the skeleton which contains the bones forming the cavity of the chest; or it is used to denote the cavity of the chest. See LUNG, where the bones and their articulations are described, as well as the cavity they form, and its contents.

THORAX. For an account of the operation of tapping, refer to EMPYEMA, PARACENTESIS, and WOUNDS of the Thorax.

The subject of wounds of the chest will be found in the article WOUNDS.

THORDO, DIACONUS or LEGIFER, in *Biography*, descended from an ancient family, was provincial judge in North Jutland, and flourished in the time of Waldemar III., or about the year 1350. He was the author of the following work; "Constitutio Voldemari Regis, per Thordonem Legiferum, &c." Ripis, 1504, et Havn. 1508, 4to.; translated into Latin together with Waldemar's Jutland Laws, and afterwards published in Ludewig's "Reliquiæ MSS." tom. xii. and also in German by Eric Krabbe, in "Westphal's Monuments." Gen. Biog.

THORDSEN, or THEODORISTURLA, called also *Frode* or *Polyhistor*, was born in Iceland, about the beginning of the 13th century. His father was Thordur Sturleson, brother to the celebrated Snorro. (See STURLESON.) He is represented to be one of the greatest Icelandic poets of his time, as well as an eminent lawyer and historian. His talents excited enemies, so that he was forcibly carried away from the island in 1263, and conveyed to Norway, where he was favourably received by the king Magnus Lagebæter, admitted into his council, and appointed his historian and dappifer, one of the highest offices at the Norwegian court. Afterwards, however, he returned to Iceland, and having been chief justice of the country for many years, died in

1284. His works are "Landnama Saga," or "Liber Originum Islandiæ," published entire by bishop Thordur Thorlakfen, Skalholt, 1688, 4to., and by J. Finnæus, Havn. 1774, 4to.:—A continuation of "Sturlunga Saga," or the history of the Sturla family, and almost the whole of Iceland, during his time, which was begun by the learned bishop Brand:—"The History of King Haager Haagenfen," published at the expence of the crown-prince Frederic:—"The History of King Magnus Lagebæter," compiled from the public records of the kingdom, the greater part of which has been lost. Gen. Biog.

THORESBY, RALPH, an eminent antiquary, the son of a considerable merchant of an ancient family at Leeds, where he was born in the year 1658. His father belonged to the body of Presbyterians, and being addicted to antiquarian studies, founded the collection entitled "Museum Thoresbium." The subject of this article was intended for a mercantile profession, and in order to complete his education, begun at Leeds, and prosecuted in London, he was sent, in his twentieth year, to Rotterdam, to acquire the Dutch and French languages. But his father dying in 1679, he succeeded him in business, married, and settled in his native town. To antiquarian researches, for which his father's example had given him an early taste, he devoted much time and attention. In the earlier period of his life he had been an occasional conformist, in common with many of those who were called Dissenters, and disgusted by the indiscreet zeal of his pastor in maturer life, as well as probably influenced by his diocesan, archbishop Sharp, he joined in full communion with the established church. His connection and correspondence with persons engaged in similar pursuits with his own were gradually enlarged: and upon communicating, by Dr. Martin Lister, an account of some Roman antiquities discovered in Yorkshire, to the Royal Society, he was admitted a member of that learned body in 1697. In 1714 he published a work in which he had been long engaged, containing a history of his native town, and entitled "Ducatus Leodensis; or the Topography of Leedes, and Parts adjacent," together with a catalogue of the antiquities, &c. contained in the Museum Thoresbium. An historical part, to which he often refers, and comprehending a view of the state of the northern districts of this kingdom in remote ages, was left in MS. continued to the sixth century; which MS. being communicated to the editors of the Biographia Britannica, was by them printed entire in the article "Thoresby." He published also "Vicaria Leodensis, or the History of the Church of Leedes," Lond. 1724, comprehending observations on the origin of parochial churches, and the ancient manner of building them, together with biographical memoirs of several clergymen. In the following year he was seized with a paralytic affection, which terminated his life at the age of sixty-eight years. Possessing an extensive acquaintance with the history of his country, genealogy and heraldry, and ancient coins and medals, he always manifested a disposition to assist those who were engaged in works of the antiquarian and biographical description. The sentiments of Mr. Thoresby were liberal and Catholic; his manners regular, and his discharge of social and religious duties exemplary. Biog. Brit.

THORIGNY, in *Geography*, a town of France, in the department of the Channel; 6 miles S.S.E. of St. Lo.—Also, a town of France, in the department of the Yonne; 18 miles S.S.E. of Provins.

THORLASKEN GUDBRAND, in *Biography*, an Icelandic writer and prelate, was born at Stadarbakke, in the district of Holum, in 1542. In 1561 he was sent to the university of Copenhagen; in 1564 he became rector of the school

school of Holum; and in 1570 he was appointed bishop of that diocese. With a view of diffusing knowledge, he established a printing-press, first at Ruputel, and afterwards at Holum, which he personally superintended. He was one of the most learned of the Icelandic bishops, but too arbitrary in the exercise of his episcopal functions. He died in 1629, in the 85th year of his age. Many considerable works, partly his own, and partly those of others, issued from his press. He also constructed a map of Iceland, which was engraved by Ortelius. Gen. Biog.

THORN, in *Geography*, a city of Prussia, situated on the Vistula, formerly the chief city of Polish Prussia. It was founded by Herman Balck, first grand-master of the Teutonic order, who built the castle of Thorn in 1231. In the following year, the foundation of the town was laid; but the building was discontinued in 1235, on account of the inconvenient situation, and Thorn was built about a German mile farther up the river, on the spot where it now stands. It is supposed to have been called Thorn, because the knights of the Teutonic order, by building this city, opened themselves a *thor* or door into Prussia. When the knights of the Teutonic order enormously abused their power throughout all Prussia, Thorn was the first city which formed the noble scheme of shaking off their oppressive yoke. The inhabitants then put themselves under the protection of Casimir the Great, king of Poland, upon advantageous conditions, as a free city. Thorn has ten gates, and is divided into the Old and the New Town, each of which had formerly its respective council, magistracy, and police. But, in 1454, they were incorporated into one city. They are, however, separated from each other by a wall and moat within the town; and without, they are defended in common by a fine double wall and moats. Thorn was formerly strongly fortified; and it gradually improved its advantageous situation, so as to become a place of very considerable trade, and one of the principal of the Hanse towns. It likewise carried on an extensive commerce in the Baltic, independently of the other cities of that confederacy; for before the river widened so much, and consequently became shallower, ships of burden could come up to the very city. From various causes, in little more than half a century, Thorn greatly declined from its flourishing condition; for it surrendered by capitulation, in 1655, to Charles Gustavus, king of Sweden; and, in 1658, after a vigorous siege, it was taken by the Poles and Brandenburgers. In 1703, it was bombarded and taken by Charles XII. king of Sweden, who not only exhausted it by the heaviest contribution, but also demolished all the fortifications, contrary to the articles of capitulation. Between the years 1708 and 1710, great numbers of its inhabitants were swept away by the plague. In the following years, the revenues of the city suffered considerably by the confederations in Poland, and no less by the commotions occasioned by the competitors for the crown of that kingdom. In 1793, some Prussian troops entered this town, and from that time it has formed part of the dominions of that king; the king of Prussia taking possession of Thorn and Dantzic, together with the palatinates of Posenania, Kalish, &c. agreeably to a proclamation, published on the 25th of March. The soap, ginger-bread, &c. of Thorn, are every where in great request; and, accordingly, great quantities of them are exported. The asparagus that grows wild on some of the city lands, is not inferior to that which is cultivated with so much care in other countries; 70 miles S. of Dantzic. N. lat. 52° 55'. E. long. 18° 30'.

THORN, or *Thoren*, a town of France, in the department of the Lower Meuse. It had a noble abbey, whose superior

was a princefs. This abbey was assessed in the matricula at one horse or twelve florins; 7 miles S.W. of Ruremond.

THORN, in *Botany*, a name generally given to all trees, or the larger kinds of shrubs, which are armed with spines or prickles, but more particularly applied to the Linnæan genus *CRATÆGUS*, now sunk in *MESPILUS*. (See those articles.) Otherwise this name is almost as vaguely applied as its Greek and Latin synonyms, *ακανθα* and *spina*, neither of which is strictly appropriated to any one plant, or family of plants. *Ακανθα*, in Dioscorides, is the name of that well-known herb, whose leaves compose the ornamental part of a Corinthian capital, and which is the Brank-ursine, or *Acanthus* of modern botanists, as well as of the generality of writers. But he applies the same likewise to a kind of thistle. The *Acanthus* of Virgil can scarcely be any thing else than the Common Holly, *Ilex Aquifolium*, though we do not find that this idea has occurred to his critics or illustrators. This shrub, so abundant in Italy, cannot be traced, under any other name or allusion, in the poet; while the bright aspect, the saffron or scarlet colour, the pliant twigs of his *Acanthus*; but, above all, its being evergreen and bearing berries, *Georg.* 2. 119, and subjected in winter to the shears of the gardener, *ibid.* 4. 137, are circumstances strikingly appropriate to the Holly, not to the Brank-ursine; though the name may allude to the prickly foliage of either.

THORN-Apple. See *DATURA*, and *DATURA Stramonium*.

THORN, Black, or *Sloe-tree*, a species of the *prunus*, called *prunus sylvestris*. See *PRUNUS* and *SLOE*.

THORN, Box. See *LYCIUM*.

THORN, Buck. See *RHAMNUS*, and *RHAMNUS Catharticus*.

THORN, Christ's. See *PALIURUS* and *RHAMNUS*.

THORN, Cockspur. See *CRATÆGUS*, *MESPILUS*, and *PYRUS*.

THORN, Egyptian, a name sometimes applied to a plant which is armed with strong thorns or prickles, and which is said to have been lately found to make a good hedge-plant when kept low by being well cut in. It is also a very ornamental shrubby tree-plant for pleasure-grounds. See *ACACIA*.

THORN, Evergreen. See *MESPILUS* and *PYRUS*.

THORN, Glasstonbury, a variety of the hawthorn. See *CRATÆGUS* and *MESPILUS*.

THORN, Goat's, a species of *Astragalus*; which see. See also *TRAGACANTHA*.

THORN, Haw. The fruit of this thorn has been found useful by farmers in feeding team and other horses. See *CRATÆGUS* and *MESPILUS*.

THORN, Lily. See *CATESBÆA*.

THORN, Purging. See *RHAMNUS*.

THORN, Scorpion's, a species of *Ulex*; which see.

THORN, Spanish Hedge-hog, a species of *Anthyllis*; which see.

THORN, White, a species of *Cratægus*; which see. See also *MESPILUS*.

THORN, in *Vegetable Physiology*. See *SPINA* and *FULCRA*.

THORN-Hedges, in *Agriculture*, a term often applied to such as are made of that plant, whether of the white or black kind. They in most cases form the best fences. See *FENCE*, *QUICKSET*, *QUICKSET-Hedge*, &c.

THORNBAC, in *Ichthyology*, the English name of a species of ray-fish, the *raia clavata* of Linnæus, prickly on the back, and with tuberculose teeth, and a transverse cartilage in the belly: the young fish have very few spines on them, and their backs are often spotted with white, and each spot encircled with black. (See *RAIA*.) This species

frequents our sandy shores, is very voracious; and feeds on all sorts of flat fish, and is particularly fond of herrings and sand-eels, and sometimes eats crustaceous animals, such as crabs. The thornbacks begin to generate in June, and bring forth their young in July and August, which (as well as those of the skate) before they are old enough to breed, are called *maids*. They begin to be in season in November, and continue so later than skate; but the young of both are good at all times of the year. Pennant.

THORNBURGH, in *Geography*, a town of Virginia; 74 miles S. of Washington.

THORNBURY, an ancient market-town in the lower division of the hundred of the same name, in the county of Gloucester, England; is situated 24 miles S.W. from the city of Gloucester, and 122 miles W. by N. from London. The town consists principally of three streets, in the form of the Roman Y, "having first," says Leland, "one longe strete, and two hornes goyne owt of it." The corporation is composed of a mayor, twelve aldermen, and a town-clerk; but the power of these officers is become much limited by disuse. A weekly market is held on Saturdays, but is not much frequented: here are three annual fairs. The church is spacious and handsome: the tower is lofty, and ornamented with rich open-worked battlements, and eight pinnacles. The population, as returned under the act of the year 1811, amounted to 1083; the number of houses to 216. At the north end of the town are the remains of an unfinished castle, which was commenced by Edward Stafford, duke of Buckingham, but stopped when he was beheaded in 1522. This castle may be considered as particularly deserving notice, from its affording some interesting specimens of the last gradation of castellated architecture. The former splendour of Richmond and Nonfuch, which were contemporary with it, are known only by description and engravings; and Hampton Court, though it rose under the hands of Wolsey at the same period, is certainly less rich in the minute and capricious ornaments peculiar to the buildings of Henry VII. and his successor. A small part most resembling Thornbury, is seen at Windsor Castle, in an addition made by the first-mentioned sovereign. It is evident, from a survey made in the year 1582, that the whole southern side was habitable, and that it consisted of several chambers, of magnificent dimensions. The tower, the walls of which are perfect, was divided into four rooms, the duke's own apartments: this stands at the south-west angle of the castle. The duke was meditating the completion of the quadrangle which would have inclosed an area of two acres and a half, when his fatal attainder closed his views for ever. Within the circuit walls twelve acres were inclosed: annexed to them are small rooms, intended as barracks for soldiers. In the reign of Elizabeth, the principal timbers were taken away; and time has forwarded the dilapidation. A singular coincidence has been remarked between the front of Thornbury castle and that of Christchurch, Oxford; and it appears as if the rivalry of the duke and cardinal Wolsey was exerted even in their architecture. — *Beauties of England and Wales*, vol. v. Gloucestershire; by J. Britton and E. W. Brayley. Lysons's "Gloucestershire Antiquities," folio.

THORNE, a market-town in the lower division of the wapentake of Stralford and Tickhill, in the West Riding of the county of York, England; is situated near the south bank of the river Don, at the distance of 10 miles N.E. from Doncaster, 29 miles S. by E. from York, and 167 N. by W. from London. The town appears to be in a progressive state of improvement: it carries on a considerable commerce by the Don; and vessels trade regularly to

London. Ships of a size sufficiently large for the coasting trade, are built at the suburb called Hangman Hill, on the banks of the river, which is also the landing-place for all the merchandize. A canal cut from the Don to the Trent passes within a furlong on the west side of the town. A weekly market is held on Wednesdays; and two fairs annually, each of three days continuance, for horned cattle, woollen cloth, &c. According to the population returns of the year 1811, Thorne contained 637 houses, the number of inhabitants being 2713. The country about Thorne is for the most part fertile; but low, flat, and totally unpicturesque. On the east side of the town is a field of rich sandy loam, and more elevated than the other lands in the vicinity. Beyond this are vast moors, which however are mostly drained and inclosed.

At the distance of about three miles westward from Thorne, and on the Doncaster road, is Hatfield, a large village, famous in the annals of history for the battle fought there A.D. 633, by Edwin, the first Christian king of Northumbria, against Cadwallo, king of Wales, and Penda, the Pagan king of Mercia. This conflict, which was extremely sanguinary, terminated fatally for the Northumbrians: their monarch, and his eldest son Offrid, were slain, their kingdom subdued, and their country laid waste. This village was the birth-place of William de Hatfield, the second son of king Edward III. The extensive level of Hatfield Chase is said to contain within its limits 180,000 acres, of which nearly one-half was formerly a great part of the year under water. It was sold by Charles I. to Cornelius Vermuiden, a naturalized Dutchman, without the consent of the commissioners and tenants, to drain and cultivate; which he effected at the expence of about 400,000*l.*, but the affair involved him in ruinous law-suits. In the year 1811, an act was obtained for inclosing between eight and nine thousand acres of rich common in this neighbourhood, which must be ultimately productive of great public and private advantage. — *Beauties of England and Wales*, vol. xvi. Yorkshire; by J. Bigland.

THORNE, a small island of Denmark, in the Little Belt, near the island of Funen. N. lat. 59° 15'. E. long. 9° 53'.

THORNESS BAY, a bay on the N.W. coast of the Isle of Wight, between Newtown and Cowes.

THORNEY, a market-town in the north part of the hundred of Witchford, and county of Cambridge, England; is situated in the north-west side of the county bordering on Northamptonshire, 10 miles W. from March, 5 miles S.E. from Crowland, and 84 miles N. from London. It is surrounded by low and fertile grounds, which are now in a very complete state of drainage, the expence of which is defrayed by an annual tax of about a shilling *per acre*. Its ancient appellation was Ankeridge, which it obtained from the anchorites who dwelt in a monastery, or rather an assemblage of hermitages, founded here about the year 662, by Saxulphus, the first abbot of Peterborough. The Danes destroyed these hermitages in 870, and the place lay waste till 972, when Ethelwold, bishop of Winchester, founded on the site an abbey for Benedictine monks, which became an opulent establishment, and ranked among the mitred abbeys. In the year 1085, the ancient church was taken down, and a new one commenced by the abbot Gunter, but it was not completed till 1128. This structure possessed considerable magnificence, and was, according to Brown Willis, "at least five times as large as at present." When the abbey was dissolved by Henry VIII. great part of the church was destroyed; but the remainder escaped by being made parochial. The west front, which is the entrance to the church,

church, is the most perfect part of the ancient building. The revenues of the abbey were estimated, at the dissolution, at 411*l.* 12*s.* 11*d.* clear yearly value. Great part of its possessions, with the scite, was granted in 1549 to John, lord Russell, ancestor to the duke of Bedford, who is lord of the manor, and owner, not only of the town, but also of 19,000 acres of the surrounding lands. This extensive property is divided into farms from 2*l.* to 400*l.* per annum, generally in a very improved state of cultivation. A market is held on Thursdays, and two annual fairs were granted for Thorney to Francis, earl of Bedford, in the 13th year of Charles I. by the charter of incorporation for the government of the Bedford Level. The inhabitants of the parish, who are chiefly the descendants of French Protestants, are stated in the population return of the year 1811, to amount to 1675: the number of houses being 251.—Lysons's *Magna Britannia*, vol. ii. part 1. Cambridgeshire. Beauties of England and Wales, vol. ii. Cambridgeshire; by J. Britton and E. W. Brayley.

THORNEY Island, a small island, in a bay of the English Channel, near the coast of Sussex, about four miles in circumference, with a village of the same name, at the mouth of the Lavant; 7 miles S.W. of Chichester.

THORNHILL, Sir JAMES, in *Biography*, may be called the father of historic painting in England. He was the son of a gentleman of an ancient family in Dorsetshire, and was born at Weymouth in 1676. His family having fallen in fortune, he was obliged to resort to some profession for support, and guided by an early taste for painting, fixed upon that art as a base on which to raise a fortune and a name. He came to London, and was assisted by the celebrated physician Sydenham, who placed him under the tuition of an artist of little note, whose name is not known, and to whom, from the state of the art at the time, he must have been far less indebted for the progress he made, than to his own ingenuity and industry. After having practised for a while with some celebrity, he travelled to Holland and to Flanders; and thence visited France, but did not proceed to Italy. Most probably his object in this journey was only to acquire a knowledge of colouring; and he might have satisfied his mind on composition and form, by having spent three years in copying the cartoons of Raphael, which he was permitted to do by the favour of the earl of Halifax. These copies are in oil, and were bought after his death by the then duke of Bedford; and by his grace's successor, the late duke, were presented to the Royal Academy. They are wrought with care, but lack the delicacy of character and feeling observable in the originals. On his return to England, his reputation was increased, and honour and employment accompanied it. Queen Anne commissioned him to paint the interior of the cupola of St. Paul's, which he did in eight compartments. The subject assigned him was the history of St. Paul; and he treated it with considerable grandeur of style, both as to composition and execution; but his design wanted chastity and simplicity, and the heads of his figures have not sufficient refinement of expression. It was, however, the first attempt by an Englishman of the kind, and fully justified the preference given to him over La Guerre and La Fosse, who were then painting the halls and staircases of our nobility. He was afterwards employed to decorate an apartment at Hampton Court, with emblematical allusions to the history of the queen, and her union with her consort, George, prince of Denmark. But his grand work is the great hall at Greenwich Hospital, where he has painted naval trophies and allegorical figures in great profusion; and if much praise cannot be given to the purity of the design, it ought not to

be withheld from the brilliancy and vigour of the execution. Altogether, it is a work unrivalled in its kind here, and well entitled him to the honour of knighthood, which George I. soon after conferred upon him. This was some compensation to him for the mortification of having his demand for these paintings contested, and being in the end paid only at the labourer's rate of so much per square yard, (4*os.*)

He had the honour of so far re-establishing his family influence as could be effected by being chosen to represent his native town in parliament; but he did not enjoy his honours long, as he died at the early age of 57, leaving a son, named also James, for whom he had procured the appointment of serjeant-painter to the king, and a daughter married to Hogarth.

THORNY TREFOIL, in *Botany*. See FAGONIA.

THORNY Rest-Harrow, in *Agriculture*, a frequent weed in poor barren pasture land, which is not removed without difficulty, in consequence of its perennial nature.

THOROE, in *Geography*, a small island of Denmark, in the Little Belt, near the island of Funen. N. lat. 55° 15'. E. long. 9° 53'.

THOROLD, a township of Upper Canada.

THOROUGH, the common name of an inter-furrow between two ridges. They should always be clean and well-drawn.

THOROUGH-Base, or accompaniment to a continued base by figures.

Thorough-base is but an awkward translation of the Italian terms *basso continuo*, by which accompaniment by figures, without any other guide for the right-hand on keyed instruments, was at first called.

The French term *accompagnement* is the shortest and most comprehensive title for the harmony expressed by figures over the base; if, as Rameau has done in his "Code de Musique," we add "for the harpsichord or organ," as there are several other kinds of accompaniment besides that on keyed-instruments.

Rameau defines accompaniment or thorough-base in the following manner. "Accompaniment on the harpsichord or organ, consists in the execution of a complete and regular harmony, by seeing only the notes of one part of that harmony; and this part is called the base, being in reality the basis or foundation of the whole composition. This base is played with the left-hand, and its harmony with the right."

We shall endeavour to assist our musical reader, who has every thing to learn in the art of accompaniment, more by example than precept, and shall give him a series of progressive lessons in the musical plates, which will explain the whole mystery of musical combinations from the common chord, to the most extraneous harmony.

We take it for granted that he is perfectly acquainted with the musical scale or gammut, in the base and treble clefs at least, as well as with the time-table; and that the accidents of flat, sharp, and natural, are familiar to him.

The first thing, therefore, that we shall recommend to his study, is a table of intervals, both in notes and figures. See *Plate II.*

N^o 1. presents a scale in half notes, in which all the flats occur, from the unison to the 9th; another scale expressed by sharps.

2. Number of semitones above the base in each interval.

3. Common chords, major and minor, to all the twelve semitones, modulating by 5ths.

4. Modulation in common chords, major and minor alternately, the base falling a 3d at each change. And in

order to familiarize the student to these chords in every part of the instrument, he is advised to make three voyages round the harmonical world: beginning with the 8th uppermost, then the 5th, and lastly the 3d; and if no mistake is made, the last chord in each of these circumnavigations will be an octave above the first. But all difficulty in these exercises will be removed, if it be remembered that, in going from chord to chord, only one note is to be changed by the right-hand, which note is always the octave of the new base.

5. Exercise of common chords in accompanying the hexachords in all the keys, major and minor, to their fundamental bases: in the practice of which, dots are placed on the notes in the treble, which are to be played with the little finger. And though only the first hexachord, or six notes, is written backwards, each of them is intended to be played backwards as well as forwards.

Many years ago, we tried to reduce all the rules of thorough-bass to the compass of a *message-card*, and almost all the combinations expressed by figures to common chords. And now, if the preceding exercises of the hand in common chords have done their duty, the student will perceive, from an engraving of the two sides of this *thorough-bass card*, that what has been explained in words and figures on one side, is illustrated with notes on the other.

The second card goes somewhat deeper into harmonical mysteries, by what the French call *la regle de l'octave*, or rule for accompanying with a specific chord every note of the key, ascending and descending; which, if practised well in all the 24 keys, and impressed on the memory, will enable the student to figure a base himself, or to play without figures; and by a seeming divination, without a treble part, to know the harmony that belongs to each base of a regular composition, in a diatonic ascent and descent.

After these chords are literally at the *fingers' ends* of the student, the following eight rules and exceptions in playing without figures must be observed.

1. An accidental *sharp* note in the base is generally accompanied with a \sharp , and changes the key to the half note above such sharp.

2. An accidental *flat* note in the base is generally accompanied with a \flat , and changes the key to the 4th below such flat.

3. To the 5th of a key, if repeated at a close, two chords are generally played in modern music; the $\frac{6}{4}$ and $\frac{5}{3}$; in old music, the $\frac{5}{3}$, and sometimes the 7th with the common chord.

4. When the base moves *per saltum*, a 3d, 4th, 5th, or 6th, common chords will do.

5. When the base rises a 4th, and falls a 5th alternately, and the contrary, each note may be accompanied by a 7th.

6. In syncopated or binding notes the $\frac{4}{2}$ are played to the last part of the ligature, by *anticipation*.

7. Slow notes in the base, in old music, are generally accompanied, as on the plate, by a \sharp and \flat alternately.

8. *Suspensions* of a whole chord, or part of a chord, are expressed by a dash (—) preceding the resolution.

The reverse of the second card contains explanations of these eight rules in notation.

It must be remembered, that whoever is ambitious of playing thorough-bass *without figures*, must previously possess the art of accompanying readily *with figures*. See COMPOSITION and COUNTERPOINT, to which thorough-bass is the best introduction: as what is good in playing, would be good, as far as *harmony* is concerned, in writing. In-

vention, fancy, and good taste, are necessary to break these chords into *melody*.

THOROUGH-Wax, in *Botany*. See BUPLEURUM.

THORP ARCH, in *Geography*, a village of England, in the county of York, where is a medicinal spring, impregnated with sulphur and steel; 3 miles S.E. of Wetherby.

THORP, *Bishop's*, a village of England, in the county of York, where the archbishop has a palace, built by archbishop Gray in 1241; 3 miles S. of York.

THORPNESS, a cape on the east coast of England, in the county of Suffolk, forming the southern part of Solebay.

THORSAKER, a town of Sweden, in Gestricia; 21 miles S.W. of Gefle.

THORSBERG, a mountain of Norway, in the province of Aggerhuus; 18 miles W. of Tonsberg.

THORSHAVEN, a sea-port town of the island of Stromoe, and capital of all the Faroer islands, as well as the common market, and residence of the laudvogt, and king's counsel.

THORSTORP, a town of Sweden, in West Gothland; 28 miles S.E. of Gotheborg.

THOS, THOUS, $\Theta\omega\tau$, in *Zoology*, a name given to an animal of the wolf-kind, but larger than the common wolf, common in Surinam. It is a species of the canis, with a light bent tail, and white belly. It never touches men or cattle, and rather provides its food by cunning than open force; preying chiefly on poultry and water-fowl.

THOTCHI, or THATCHI HOTUN, in *Geography*, a town of Chinese Tartary; 368 miles W. Tourfan. N. lat. $42^{\circ} 52'$. E. long. $83^{\circ} 24'$.

THOTRA, a town of Hindoostan, in the circle of Rantampour; 40 miles S.S.W. of Rantampour.

THOU, JAMES AUGUSTUS DE, (THUANUS,) in *Bio-geography*, an eminent magistrate and historian, was the son of Christopher de Thou, president of the parliament of Paris, distinguished for integrity and patriotism, and born at Paris in the year 1553. In the college of Burgundy, where he was placed at the age of ten years, his education was interrupted by a fever, which seemed for some time to have proved fatal to him; but upon his recovery he studied the civil law, first at Orleans, and afterwards at Valence, under the celebrated Cujacius, in which latter place he commenced an intimate acquaintance with Joseph Scaliger, which was continued through life. Upon his return to Paris in 1572, he witnessed the horrors of the massacre of St. Bartholomew, and this scene impressed him with an eternal detestation of bigotry and intolerance. He was originally destined for the church, with the prospect of valuable preferments, which his uncle, the bishop of Chartres, intended to resign to him. In the mean while he travelled to Italy, the Low Countries, and Germany; but upon the death of his brother, his views were changed, and the law became his destined profession. After the death of his father, whose memory he held in high veneration, he was made master of requests in 1584; and in 1587, he married Marie Barbanfon, a lady of a noble family. Upon the revolt of Paris, on occasion of the league, in 1586, he repaired to Henry III. at Chartres, and was deputed by him to confirm the province of Normandy in its allegiance. On the assassination of the duke of Guise, his family at Paris received public insults, which made it necessary for his wife to make her escape in disguise, and he went to the king at Blois, who was almost deserted, and induced him to form a coalition with Henry, king of Navarre. Being at Venice, he was informed of the assassination of Henry III., after which he immediately joined the legitimate successor to the crown,

crown, Henry IV., at Chateaudun. The king, fully apprized of his excellent qualities, reposed confidence in him, and employed him in many interesting negotiations. On the death of Amyot, the king's principal librarian, De Thou was nominated his successor; and in 1594 he succeeded his uncle as "president á mortier." He officiated as one of the Catholic commissioners at the theological conference of Fontainebleau between Du Perron and Du Plessis Mornai; and in the regency of Mary de Medicis, he was one of the directors-general of the finances. At the conference of Loudun, he acquired distinguished reputation by his virtue and ability; and he was joined with cardinal Du Perron in a commission for the reform of the university of Paris, and the construction of the college-royal, the edifice of which was begun under his superintendance. Although De Thou was occupied in a variety of public transactions, he reserved time for the cultivation of literature, and particularly for that of Latin verse, in which latter department he published, in 1584, a didactic and descriptive poem, "De Re Accipitraria," (on Hawking,) which was well received by the learned. He also gave to the public other pieces of Latin poetry, some of which were on scriptural subjects. But his "Opus majus," as we may call it, which has established his permanent fame, was "The History of his own Times," the first part of which appeared in 1604. The condemnation of this interesting work reflects indelible discredit on Henry IV. and his court: the ground of their enmity seems to have been the freedom with which he spoke of the popes, clergy, and the house of Guise, and the disposition he manifested to extenuate the offences charged upon the Huguenots, and to extol the virtues and abilities of that sect. Our author's History, when completed, consisted of 138 books, comprehending the events from 1545 to 1607. No person could be better qualified for undertaking such a work; and when we consider his native candour and love of truth, no one was more likely to execute it with impartiality. Mr. Hayley, in his "Essay on History," has with equal justice and eloquence characterized this illustrious writer in the following lines:

"There, in the dignity of virtuous pride,
Thro' painful scenes of public service try'd,
And keenly conscious of his country's woes,
The liberal spirit of Thuanus rose:
O'er earth's wide stage a curious eye he cast,
And caught the living pageant as it past:
With patriot care most eager to advance
The rights of nature, and the weal of France!
His language noble, and his temper clear
From faction's rage, and superstitious fear!
In wealth laborious! amid wrongs sedate!
His virtue lovely, as his genius great!
Ting'd with some marks that from his climate spring,
He priz'd his country, but ador'd his king;
Yet with a zeal from slavish awe refin'd,
Shone the clear model of a Gallic mind."

To this work De Thou has annexed "Commentaries or Memoirs of his own Life."

Having lost his first wife in 1601, whose virtues he celebrated in a Latin poem; and having no issue, he married, in 1603, a second wife, of a noble family, by whom he had three sons and three daughters, and she died in 1616. This loss, and the calamities that befel his country on the murder of Henry IV., are supposed to have hastened his own death, which happened in 1617, at the age of 64 years. His library, which was very valuable, and which by his will was to have been kept undivided in his family, was nevertheless sold

after the death of one of his sons. The most complete edition of De Thou's History is that published at London in 1733, by Buckley, in 7 vols fol. with memoirs of his life, and other pieces not before published. Dr. Mead, always distinguished as the munificent patron of letters, contributed to render this edition peculiarly valuable, by the purchase of Carte's papers, which he had collected during his residence in France.—Mem. of De Thou, by himself. Moreri. *Nouv. Dict. Hist. Gen. Biog.*

The eldest son of De Thou, viz. *Francis Augustus de Thou*, born in 1607, inherited the virtue and talents of his father, and became a master of requests, and afterwards grand-master of the royal library, and acquired, by the gentleness of his manners and profound learning, general esteem. But falling under the displeasure of cardinal Richelieu, he was kept out of all confidential employments; and by this slight he was induced to join the party of the favourite Cinquars, who entered into a secret negotiation with Spain. De Thou was implicated in the conspiracy, and capitally condemned. He was beheaded at Lyons, in 1642, at the age of 35, dying with great resolution, and universally lamented; a victim to the vindictive feeling of Richelieu, because his father, in his History, had spoken in opprobrious terms of one of his family.

THOUARCE', in *Geography*, a town of France, in the department of the Mayne and Loire; 12 miles S. of Angers.

THOUARE', a town of France, in the department of the Lower Loire; 5 miles N.E. of Nantes.

THOUARS, a town of France, and principal place of a district, in the department of the Two Sevres, near the river Thoue. The place contains 2035, and the canton 13,950 inhabitants, on a territory of 317½ kilometres, in 24 communes; 31 miles W. of Poitiers. N. lat. 46° 58'. E. long. 0° 8'.

THOUE, a river of France, which runs into the Loire, a little below St. Florent.

THOUGHT, SENTIMENT, a general name for all the ideas consequent on the operations of the mind, and even for the operations themselves.

As, in the idea of thought, there is nothing included of what we include in the idea of an extended substance; and that whatever belongs to body, may be denied to belong to thought; we may conclude, that thought is not a mode of extended substance, it being the nature of a mode not to be conceived, if the thing, of which it is the mode, be denied. Hence we infer, that thought, not being a mode of extended substance, must be the attribute of some other substance very different.

F. Malebranche, with the spirit of a Cartesian, denies that a man who thinks seriously on the matter, can doubt but that the essence of the mind consists altogether in thought, as that of matter does in extension; and that, according to the various modifications of thought, the mind sometimes wills, sometimes imagines, &c.; as, according to the various modifications of extension, matter is sometimes water, sometimes wood, fire, &c. By the way, by thought he does not mean the particular modifications of the soul, *i. e.* such or such a thought, but thought, or thinking in the general, considered as capable of all kinds of modifications, or ideas; as by extension he does not mean such or such an extension, as a square, oval, or the like, but extension in the abstract, considered as susceptible of all kinds of modifications or figures.

He adds, that he takes it to be impossible to conceive a mind which does not think, though it be easy to conceive one which does not feel, or imagine, or will; in like manner

as it is impossible to conceive a matter which is not extended, though it be easy to conceive one that is neither earth nor metal, nor square, nor round, nor that is even in motion.

Hence it may be concluded, that as it is possible there may be matter which is neither earth nor metal; nor square, nor round, nor even in motion; it is also possible, that a mind may neither perceive heat nor cold, nor joy nor grief, nor imagine any thing, nor will any thing; so that these modifications are not essential to it. Thinking alone, therefore, according to this author, is the essence of the mind, as extension alone is the essence of matter.

But this doctrine is not now generally received. The followers of Sir Isaac Newton, and the new philosophy, deny extension to be the essence of matter; and the followers of Mr. Locke deny thought to be the essence of the mind.

THOUGHTS, or *Thoughts*, in a *Boat*, a name given by seamen to the benches on which the men sit down to row.

THOUINIA, in *Botany*, a noble genus, though consisting of only one known species, so named by the writer of this, in grateful remembrance of his distinguished friend M. André Thouin, member of the Institute, and at present Professor of Agriculture at Paris. This gentleman is one of the original foreign members of the Linnæan Society, and ranks among the best and most philosophical cultivators, as well as botanists, of this or any age. The present plant was selected out of the large and fine collection of new and rare specimens, given by himself to the younger Linnæus, chiefly from the herbarium of Commerçon. We were not aware of its having been named *Humbertia* by its discoverer, or *ENDRACHIUM* by Lamarck (see the latter article); where we have remarked that the name is barbarous; we should therefore not have adopted it, if known. *Humbertia* is not accounted for, there being no botanist on record of the name of Humbert, nor has any body explained or defended this appellation. The younger Linnæus had indeed established a *Thouinia*, *Suppl.* 9, after Thunberg; neither of them suspecting their plant to be a real *Chionanthus*, the *zeylanica* of Linn. *Sp. Pl.* 11. Swartz moreover, in his *Prodr.* 14, added a second species to this supposed genus, which he afterwards distinguished from it, by the name of *LINOCLERA*, under which head our doubts respecting even that matter are recorded. Considering therefore our original name no more justly superfluous than our genus, we cannot allow it to give place to M. Poiteau's *Thouinia*, *Ann. du Muséum fasc.* 13, though De Theis has decided otherwise.—*Sm. Plant. Ic.* 7. Schreb. 793. Willd. *Sp. Pl.* v. 1. 935. Mart. *Mill. Dict.* v. 4. (*Endrachium*; *Juss.* 133. *Humbertia*; Lamarck *Dict.* v. 1. 356. *Illustr.* t. 103.)—Class and order, *Pentandria Monogynia*. *Nat. Ord.* *Convolvuli*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, permanent, of five rounded, coriaceous, concave leaves; the three outer ones most thick and rugged, naked; two inner membranous at the margin, silky at the back. *Cor.* of one petal, twice the length of the calyx, bell-shaped, plaited, externally bristly; its margin in five triangular blunt segments. *Stam.* Filaments five, awl-shaped, smooth, declining, twice the length of the corolla, and inserted into its base; anthers incumbent, heart-shaped, of two lobes. *Pist.* Germen superior, ovate, very hairy; style of the length, figure, and situation of the stamens, a little swelling upward; stigma obtuse, notched. *Peric.* Berry globose, coriaceous, standing on the permanent calyx, of two cells. *Seeds* two in each cell, triangular, somewhat ovate.

Ess. Ch. Calyx inferior, of five unequal leaves; permanent. Corolla of one petal, bell-shaped; externally

bristly. Style simple. Berry coriaceous, of two cells. Seeds two in each cell.

Obs. We see no reason to adopt Jussieu's or Lamarck's idea of this fruit. They call it a coriaceous, or woody, capsule, which does not burst. Commerçon, who alone has examined it fresh, denominates it a *drupa*, which term we would restrain to pulpy fruits with a single nut, and therefore we judge the present to be a *bacca*, however tough or dry its substance may appear when dry.

1. *T. spectabilis*. Beautiful *Thouinia*. *Sm. Pl. Ic.* t. 7. Willd. n. 1. (*Humbertia madagascariensis*; Lamarck n. 1. "H. ævitermia; Commerçon. MSS. et Ic. *Endrach-Endrach*; Flac. *Hist. Madagasc.* 137. f. 100. *Arbre immortel*.)—Native of Madagascar; unknown in the gardens of Europe. A tall and large tree, whose wood is yellowish, compact, heavy, as hard as iron, and almost incorruptible even under ground. Lamarck. The branches are round, scarred, silky towards the ends, where they bear tufts of leaves, intermixed with axillary flowers. The leaves are scattered, two or three inches long, obovato-lanceolate, obtuse, entire, smooth and shining, with a strong mid-rib, on channelled silky footstalks, without stipulas. Flowers on solitary, axillary, simple stalks, rather shorter than the leaves, each with a pair of small bracts about the middle. Of the colour of the corolla we have no account; its length is about an inch; and the silky hairs on the outside, in a dry state, are of a shining brown. Fruit the size of a small plum.

THOUN, in *Geography*, a town of Persia, in the province of Khorassan; 75 miles W. of Herat.

THOURY, a town of France, in the department of the Eure and Loire; 3 miles E. of Janville.

THOUSAND. See NUMERATION.

THOUSAND Years' Reign. See MILLENNIUM.

THOUSAND Islands, in *Geography*, a cluster of small islands in the Straits of Sunda. S. lat. 5° 33'. E. long. 106° 33'.—Also, a number of small islands in the river St. Laurence, a little below lake Ontario; the part of the river being called Thousand Island Lake.

THOUSAND Lakes, a name given to a number of small lakes in America, near the river Mississippi; 60 miles above St. Anthony's Falls.

THOUSAND Rocks, rocks in the river St. Laurence; 72 miles S.W. of Montreal.

THOWLES, in a *Boat*. See THOLES.

THOYNARD, NICHOLAS, in *Biography*, a native of Orleans, was born in 1629, and at an early age a proficient in the learned languages, and in medallic science. His own original works were few, but he was liberal in the assistance he afforded to other writers. He published two short Latin dissertations on particular medals, and notes upon "Lactantius de Mortibus Persecutorum," and also a Critique on R. Simon's translation of the New Testament; but his principal performance was "A Concord of the Four Evangelists," in Greek and Latin, which was printing at the time of his death at Paris in 1706, and appeared in 1707, with learned notes, chronological and historical. In this work he maintains that St. Matthew, of all the evangelists, paid the least regard in his narrative to the order of time. This work was printed at considerable expence, and is now rare. Moreri.

THOYT. See THAUT.

THRACE, in *Ancient Geography*, an extensive country of Europe, situated in the S.E. Its natural boundaries are, on the S. the Ægean sea, the Propontis, and the Bosphorus of Thrace; on the E. the Euxine sea. Its limits to the N. and W. are not so determinately ascertained.

A penin-

A peninsula to the S., between the Melanic gulf and the Hellespont, made part of the continent of Thrace, but it assumed the name of the Chersonesus of Thrace.

The continent may be considered as divided into six parts: *viz.* 1. The part bounded to the W. by the river Melas, which discharged itself into a gulf of the same name. To the S. it had the Chersonesus and the Propontide, and to the E. the Bosphorus of Thrace and the Euxine sea. The chief towns of this part were, on the borders of the Propontide, Ganos, Bisanthe or Rœdestus, Perinthus called also Heraclea, Selymbria, Byzantium; and on the Euxine sea, Dercon, Salmydessus.

2. The second part of Thrace extended from Melas to the Hebrus. It had several towns on the banks of the Hebrus, of which, the principal were Philipopolis and Adrianopolis, called also Orestes, and Trajanopolis. The Hebrus took its rise in mount Hæmus, and discharged itself into the Melanic gulf, near the town of Enos.

3. The third part lay between the Hebrus and the lake Bittonis to the W., consisting, according to some authors, of two subdivisions, *viz.* from the Hebrus to Lissus, and from Lissus to the lake Bittonis. On the sea-coast was situated Maronea, and in the interior of the country Scaptahyla, enriched by its mines.

4. The fourth part was narrow, and lay between the lake Bittonis and the Nestus to the W. The Nestus had its source to the N.W. of mount Rhodope, and near it were the towns of Jamphorinum and of Nicopolis ad Nestum.

5. The fifth part was situated N. of the Tæarus, a river which had its source in the mountains S. of Delnetum, and not far from the Euxine sea, and which ran into the Hebrus on the left side of it.

6. The sixth part lay N. of that part of the Hebrus which ran from Bessa towards the S.E. to Orestis. In this part were the towns of Berœa and that of Cabyla, S. of the Hæmus.

The Chersonesus of Thrace had for its boundaries to the S.E. the Hellespont and a small portion of the Propontide; to the N. the continent of Thrace; to the N.W. the Cardiac or Melanic gulf; this is the peninsula of Romania; and a wall separated it from the continent.

Those who seek the origin of the Thracians in the Old Testament, trace them to Tiras, one of the first descendants of Japhet. But whatever was the origin of these ancient people, it is certain that they were warlike and ferocious, and lived very much like savages. They were divided into different hordes, like the ancient Scythians or modern Tartars. This country, on account of the coldness of its climate, attributed to its mountains, was regarded by the Greeks with a kind of horror.

Thrace, in the Notitia Imperii, is divided into six provinces, *viz.* Europe, Rhodope, Thrace, Heminont, the second Mœsia, and Scythia. According to the Notitia of Hierocles, these six provinces contain 53 cities, of which the Thrace of Europe contained 14.

Thrace was anciently governed by kings; of these, the first who gave them laws for regulating and civilizing their manners was Zamolxis, a disciple of Pythagoras. Our limits will not allow us to trace its subsequent history, as far as it is known. The whole, or various parts of this country were possessed by Philip of Macedon, by the Athenians, by the Lacedæmonians, and by Alexander, who made a conquest of the whole country, nor did they recover their liberty till after his death. Lyfimachus, one of the successors of Alexander, was vanquished by a descendant of one of the ancient sovereigns of Thrace. But the tranquillity of the country was of short duration; for a party of Gauls,

under Brennus, ravaged Greece, and took possession of Thrace. The Thracians afterwards exterminated the Gauls, and restored the race of their ancient kings. This prince, whose name was Seuthes, and his descendants, reigned without interruption till the time of Vespasian, who reduced Thrace into a Roman province. It afterwards became subject to the Turks, who now possess it. See ROMANIA.

THRACES, or THRACIANS, in *Antiquity*, were an order of gladiators, reputed to be the most fierce and cruel of all. They were so called, either because they were natives of Thrace, or wore armour after the manner of that country. The particular weapon they used was the *fica*, or faulchion, and their defence consisted in a *parma*, or a little round shield, proper to their country.

THRACIA GEMMA, a stone mentioned by Pliny, and described by him to be of three kinds: the one of a plain green, but a considerably deep and strong colour; the other of a paler green, without variegation; and the third spotted with blood-coloured spots. This is a short description, but the stone seems to have been a jasper, of the nature of our green Oriental jasper and heliotrope.

THRACIUS LAPIS, in the *Natural History of the Ancients*, a stone often mentioned, and first called *Bene lapis*, from the place where it was first found, which was in the neighbourhood of Bina, or Bena, a town in Thrace. It has been by some authors allowed a place in the catalogues of the materia medica; but it is impossible for us to say, with any certainty, which, of several substances now known (which all answer in some degree to the accounts left us of it) is the real body they meant by that name.

It was an inflammable body, found in mines, and in the beds of rivers; and, in burning, afforded a very offensive smell.

Some of the late authors have supposed it was our common pit-coal the ancients expressed by this name; others, that it was jet; and others, the common cannel coal. Hill's *Theophrastus*, p. 34.

THRANITÆ, in the *Roman Trireme-gallies*, or those which had three rows of rowers; those of the upper row were called by this name, the second the *zygite*, and the lowest *thalamite*.

The *zygite*, or middle row of men, in these vessels, took up but very little room, having a conveniency of moving their hands and oars under the seats of those who sat next before them. See ENNERIS and POLYCROTA.

THRAPSTON, in *Geography*, a small market-town in the hundred of Navisford, and county of Northampton, England; is situated on the southern banks of the river Nen, 22 miles N.E. by E. from the town of Northampton, and 75 miles N.N.W. from London. The town, in general, is well-built; and at the west end is a handsome stone bridge crossing the Nen. By this river a considerable trade is carried on with Lynn, Northampton, and various other towns in its course. The country round Thrapston is open, and affords extensive prospects: from an eminence, half a mile to the south-east, may be seen at one view thirty-six church towers and spires. An annual court-leet and court-baron is held here; at which are appointed the governing officers, a constable, and a thirdborough; and also bread-weighers, whose office is to see that the bread, butter, and every other marketable commodity, is good and of just weight. A well-supplied market is held on Thursdays; it is the largest mart for hogs in the country: that branch alone returns every market-day, on an average, about 500*l.* Here are also two annual fairs, besides a large market, equal to either of the fairs, which is held yearly at Michaelmas. The population
return

return of the year 1811, states the number of houses in this town to be 133, occupied by 708 persons. It appears from Leland, that there was formerly a monastic establishment here. He says, "At the very end of Thrapeston bridge stand ruins of a very large hermitage, and principally well buildid, but a late discoverid and suppressid."—*Beauties of England and Wales*, vol. xi. Northamptonshire; by J. Evans and J. Britton.

THRASEA PÆTUS, in *Biography*, a Roman senator, who deserves to be recorded for his integrity and patriotism, was a native of Padua; educated in Stoical tenets, and a great admirer of Cato of Utica, whose life he composed. As a senator, he was a strenuous assertor of the liberty that remained under imperial despotism, and on this account he exposed himself to the obloquy of all the sycophants of power. His integrity commanded the acknowledgment of Nero, the execrable tyrant who put him to death, and many instances occur of his undaunted fortitude in maintaining it. We can only select the following: After Nero had committed the detestable crime of matricide, when the servile senate was decreeing solemn thanksgiving and annual festivals to commemorate the event, Thrasea, who, we are told, had been accustomed to suffer other adulations to pass in silence, or with a slight assent, marked the profligacy of these motions by walking out of the senate-house; thus openly exposing his life to a danger which he contemned; for, conformably to the Stoical principles, he was used to say, 'Nero may kill me, but he cannot hurt me.' But though Thrasea often escaped the brutal vengeance of this imperial tyrant, his fate was at length decreed. In the year 66, the 13th of Nero, this monster having imbrued his hands in the blood of many of the most illustrious Romans, now resolved, says Tacitus, to extirpate virtue itself, by the destruction of Thrasea Pætus and Barcas Soranus. The amount of the charges against Thrasea only evinced his contempt of the base adulation of the senate, and his displeasure with the vices and enormities of the reign. No defence could be of any avail, and therefore Thrasea prepared in silence to submit to his fate. When the determination of the senate was announced to him, he was in his garden surrounded by a number of illustrious persons of both sexes, and attentively listening to Demetrius, a Cynic philosopher, who was discoursing on the nature of the soul, and its separation from the body. Having received the decree of the senate, he retired into his bed-chamber, and laid bare the veins of both arms, and then bled to death. Tacit. Annal. Suetonius. Dion Cass. Plin. Epist.

THRASHING, &c. in *Agriculture*. See **THRESHING**.

THRASOS, a term used by Hippocrates, to express a wildness and fierceness in the eyes of persons who approach to a delirium.

THRASYBULUS, in *Biography*, an eminent Athenian, was the son of Lycus, and the restorer of liberty to his country. When the government of the 400 succeeded the overthrow of the democracy in the year B.C. 411, he was commander of a galley; and in connection with Thrasyllus, he destroyed the aristocracy in the camp at Samos, and re-established democracy there, and then proposed the recall of Alcibiades, in exile at Magnesia, and restored him to his country. Thrasybulus and Thrasyllus, having pursued the Peloponnesian fleet, brought it to an action in the straits between Sestos and Abydos, in which the Athenians captured 20 ships of the enemy, with the loss of 15 of their own. Another engagement soon after occurred, and the result of the arrival of Alcibiades's squadron was a complete victory on the part of the Athenians. When Alcibiades was made general of the Athenian forces both by sea and land, he nominated Thrasybulus for one of his colleagues;

but a misunderstanding afterwards taking place between them, Thrasybulus impeached Alcibiades before an assembly of the Athenians, and procured his disgrace. On occasion of the establishment of the thirty tyrants at Athens by the influence of the Lacedæmonians, Thrasybulus was one of several other citizens who took refuge in the Theban territory; and zealous for the emancipation of his country from servitude, he engaged a small body of fugitives to join him in an expedition to Attica, and took possession of the important fortress of Phyla, on the frontiers of Bœotia. Besieged by the Greeks, Thrasybulus by his activity repulsed them, and even followed them in disorder to Athens. Having also surprised a post which they occupied near Phyla, the thirty tyrants removed from Athens to Eleufis, and Thrasybulus seized this opportunity of attacking the Piræus, and his enterprise succeeded. He then issued a proclamation, animating the Athenians to resist their tyrants, and to restore a free government. Having done this, he established himself in the Piræus. The constitution of Athens was then changed, by substituting instead of the thirty tyrants, ten magistrates, one from each tribe. The Lacedæmonians still retained their influence over these magistrates, who fell to Sparta soliciting assistance against Thrasybulus. At length, however, this resolute commander prevailed so as to open a negotiation between the Athenians and the Spartan government, which terminated in the withdrawing of the Spartan garrison, and the re-establishment of a popular constitution at Athens. This happy close of the contest was followed by the union of citizens of both parties, in a solemn thanksgiving to Minerva at her temple in the citadel, when Thrasybulus exhorted them to future concord. The remaining tyrants at Eleufis endeavoured to foment dissensions in Athens; but the business terminated in an act of amnesty or oblivion, which was passed by the influence of Thrasybulus in the assembly of the people, and ratified by an oath. This revolution happened in the year B.C. 401. In accomplishing this event, Thrasybulus acted with the most disinterested patriotism; for the thirty tyrants, when he seized the castle of Phyla, had offered to make him one of their number, and to pardon any twelve of the exiles whom he might name; to which offer he replied, that exile was much more honourable than any civil authority purchased on such conditions. Thrasybulus remained for some time in unmoletted retirement, enjoying the honour accompanying the olive wreath, which, according to the simple manners of the age, was bestowed upon him for his services. But in the year B.C. 390, after the death of Conon, the foreign possessions and influence of the Athenians were in danger of being lost; and therefore a fleet of forty ships was placed under the command of Thrasybulus, with which he failed to the Hellespont. On this occasion he induced two Thracian princes to become allies to Athens, and compelled the Byzantines and the inhabitants of some other cities to abolish their aristocratical governments, and accept of the Athenian model and alliance. He next proceeded against the isle of Lesbos, in the Lacedæmonian interest, and reduced the whole island to obedience. Thence he failed for Rhodes, having previously raised supplies from the maritime towns of Asia, and the capital of Pamphylia. He also indulged his men in private pillage; and thus so much provoked the inhabitants, that they made an attack in the night on the tents, and put a number of the Athenians to the sword, among whom was Thrasybulus himself. Such was the inglorious termination of a life that had been devoted to the benefit of his native country. Corn. Nepos. Un. Hist. Gen. Biog.

THRAVE, or **THREAVE**, of *Corn*, in most parts of England, is twenty-four sheaves, or four shocks of six sheaves to

to the shock: though, in some counties, they only reckon twelve shocks to the thrave.

King Athelstan, anno 923, gave by charter, to St. John of Beverley, four thraves of corn for every plough-land in the East Riding of Yorkshire.

“ Ya fou *threve* be heaven king,
Of ilka plough of est riding.”

THRAUPIS, in *Ornithology*, a name given by many authors to the bird more commonly called citrinella.

THRAUSMA, a name given by the ancients to a kind of gum ammoniacum, which was drier than the common, and more easily crumbled to pieces.

THRAUSTOMICTHES, in *Natural History*, the name of a genus of compound earths. The word is derived from the Greek *θραυστος*, brittle, and *μικθεις*, mist.

The bodies of this genus are loams composed of sand and a less viscid clay, and are therefore of a friable or crumbly texture.

The earths of this genus are generally used to make bricks; and there are several species of them. Hill.

THREAD, in the *Linen Manufacture*, a small line or twist of flax, the weaving of which composes cloth. There is a stronger kind made use of to sew the seams of linen garments, or to mend them. The same term is applicable to cotton or wool. See **SPINNING**.

Thread, says an eminent French writer (Pajot des Charmes), bleached by the oxygenated muriatic acid, may be used by the sempstresses with much greater speed and briskness than thread of the same quality bleached in the field: it is less brittle, and may be struck much more effectually home to its place in weaving, and does not move afterwards. This information, he says, was received by him from impartial and unprejudiced manufacturers.

The thread of the Laplanders is very fine, white, and strong, but it is of a very different nature from our's; they know nothing of flax or hemp, nor of any other plant whose stalks might supply the place of these in making thread, but their's is made of the sinews of the rein-deer.

They kill of these animals a very great number continually, partly for food, partly for the skins, which they use in clothing themselves, covering their huts, and on many other occasions; the sinews of all they kill are very carefully preserved, and delivered to the women, whose province it is to prepare this necessary matter. They beat the sinews very well, after having steeped them a long time in water, and then they spin them out.

The thread they thus make is of any degree of fineness they please; but it is never any longer than the sinew from which it is made. They use this in sewing their clothes, shoes, gloves, &c. and the trappings of their rein-deer. The threads of the same sinew are laid up together, and are all of a length; and as the different sinews afford them very different lengths, they accordingly pick out such as the present use requires, both in regard to length and fineness. This sort of thread is made with much more labour than our's; but it is greatly superior to it on many occasions, where strength is rather required than beauty.

These people have, besides this, a way of making a sort of yarn of sheep's wool, which they weave into garters and a sort of ribbands, used by way of ornament; but they place no value on it, because of its want of strength. Scheffer's Hist. Lapland.

THREAD, in *Botany*, is understood of those capillaments usually found in the middle of flowers, as in the lily, tulip,

rose, &c. There are two kinds; those which support apices, are particularly called *stamina*; and those which have none, *pybilla*.

THREAD, *Gold*. See **GOLD**.

THREAD, *Virgin's*. See **VIRGIN**.

THREADS, *Air*, a term used by some to express those fine long white filaments, or thready substances, which we meet with in vast numbers floating about in the air in August and September.

The world has been much perplexed about the generation of these, till it was known that they were the work of spiders, and that they served those creatures to move from place to place by. They are long, downy, and very soft, and though they hold together when untouched, they stick to the fingers in handling, and easily break with a light touch.

The general method of these creatures spinning and weaving the webs, is by letting down the thread, then drawing it after them, and so disposing it as they think proper; but in the midst of their work of this sort, if they are closely observed, they will be sometimes found to desert, and turning the tail to the contrary way of the wind, they will emit a thread with great violence, no less than that with which a jet of water is discharged from a cock. In this manner they continue darting forth the thread, which the wind takes, and carrying it forwards, it soon becomes many yards long. Soon after this the creature will throw herself off from the web, and trusting herself to the air with this long tail, will ascend swiftly, and to a great height with it. The fragments of these lines, or the whole lines, and the spiders attached to them, though unobserved, make these air-threads, and the use nature designs them for, is evidently the wafting of the creature along the air, and giving it an opportunity of preying on gnats, and many other insects that inhabit the air, out of the reach of these creatures by any other means.

When the threads are newly spun, they are always single, and are generally seen ascending higher and higher in the air; but when they are seen coming down, they are found sometimes composed of three or four others, and either without any spider at the ends, or with two or three, or more. It is plain that this happens from the meeting of these threads one with another in the air, and their tangling together; and this incommodes the creatures, and brings them down.

These are what fill the air with the loose threads we see in autumn; and as these soon entangle together, and bring one another down, it is no wonder that they are more frequent in the lower regions of the air, than those with the spiders adhering to them, which usually rise to great heights, and sustain themselves there. And hence the origin of the threads was much perplexed among the enquirers, because they were found without any mark of the animal to which they owed their existence. The business of feeding is not all the use of these threads, but the creatures evidently sport and amuse themselves by means of them, floating about in the air, and changing height and place at pleasure.

When a spider has once raised itself from the earth in this manner, it does not descend always on the same thread it arose by, but draws that up at times, and winds it up into a hank with its fore-feet, and darts out another by way of support; and the new thread is made more or less long, as it is intended for a higher or lower flight. Philos. Transl. N^o 50.

THREAD of Glass may be obtained of indefinite minuteness by means of the blow-pipe. When no thicker than

fine hair, it is extremely flexible and elastic; and if still finer, it may be wound almost like common thread without breaking. The way of doing it is very simple. A piece of glass tube is heated in the lamp, and the end drawn out into a thread by means of another piece of glass cemented to it. When a fine thread is once drawn, the end is carried round a reel or wheel two or three feet in diameter, and by turning the wheel and continuing to heat the tube, an endless thread is drawn out, winding round it as long as the artist pleases or the glass lasts. The quicker the wheel revolves, and the hotter the glass is kept, the firmer is the thread, which may thus be made as delicate as a single silk-worm's thread, with extreme flexibility. Different coloured threads are made in this way by using very deeply coloured glasses instead of common glass.

THREADS, in *Glass*. See **GLASS**.

THREAF, in *Agriculture*, a term signifying a handful, a bundle, or a pottle, in different districts of the country.

THREATENING LETTERS, in *Law*. By statute 9 Geo. I. c. 22. amended by stat. 27 Geo. II. c. 15. knowingly to send any letter without a name, or with a fictitious name, demanding money, venison, or any other valuable thing, or threatening (without any demand) to kill any of the king's subjects, or to fire their houses, out-houses, barns or ricks, is made felony without benefit of clergy. This offence was formerly high treason, by 8 Hen. V. c. 6.

The offence of sending letters, threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort from him any money or other valuable chattels, is punishable by stat. 30 Geo. II. c. 24. at the discretion of the court, with fine, imprisonment, pillory, whipping or transportation for seven years. Blackst. Com. book iv.

THREATS, a species of personal injury. Threats and menaces of bodily hurt, through fear of which a man's business is interrupted, are comprehended under this description. A menace alone, without a consequent inconvenience, does not constitute the injury; but, to complete the wrong, there must be both of them together. The remedy for this is in pecuniary damages, to be recovered by action of trespass, *vi et armis*; this being an inchoate, though not an absolute violence. Blackst. Com. book iii.

THREAVE. See **THRAVE**.

THREE Chapters. See **CHAPTER**.

THREE Legs, Compasses of. See **COMPASSES**.

THREE, Ombre by. See **OMBRE**.

THREE, Rule of. See **RULE**.

THREE-legged Staff, an instrument consisting of three wooden legs, made with joints, so as to shut all together, and to take off in the middle, for the better carriage; and usually having on the top a ball or socket: its use is to support and adjust instruments for astronomy, surveying, &c.

THREE-pointed Pick, in *Agriculture and Rural Economy*, a tool of the pick-kind, having the broad end formed in a three-toothed manner, about six inches in length, of great strength, and having the width, from the outsides of the teeth or prongs, of about six inches. The other end is formed in the gently curving ordinary one-pointed manner. When complete, it is provided with a handle of the strong wooden kind, inserted into the eye or socket of the head-part.

THREE-pronged Fork, a name sometimes applied to the common fork which is employed for various purposes on farms. See **PRONG** and **SPUD**.

THREE-share Horse-hoe, a light three-shared tool of the

horse-hoe kind, for one horse, which is often found very convenient and useful in working the intervals of ridged turnip crops, and those of similar kinds, as well as for different other purposes of tillage husbandry.

It is constructed and wrought somewhat in the form and manner of the common plough, the hoe parts being so contrived and set as to pare and clean the sides and bottom of each of the ridges in the same operation. See *Horse-Hoe*.

THREE Brethren Hill, in *Geography*, a town of Scotland, in the county of Selkirk; 5 miles N.W. of Selkirk.

THREE Brothers, three islands in the Indian ocean. S. lat. 3° 44'. E. long. 62° 25'.—Also, three islands in the East Indian sea. N. lat. 10° 42'. E. long. 108°.—Also, three small islands on the coast of Guiana, in the mouth of the Essequibo.—Also, three small islands in the Indian sea, near the E. coast of Madagascar. S. lat. 13° 20'. E. long. 51° 10'.—Also, three small islands in the East Indian sea. S. lat. 5° 30'. E. long. 132° 15'.—Also, three small islands in the Atlantic, near Prince's island. N. lat. 1° 32'. E. long. 7°.—Also, three small islands in the East Indian sea, near the W. coast of Amboyna. S. lat. 3° 39'. E. long. 128° 18'.—Also, small islands in the East Indian sea, near the S.W. coast of Celebes. S. lat. 5° 25'. E. long. 119° 38'.—Also, small islands in the bay of Gunong Tellu, on the coast of Celebes. S. lat. 1°. E. long. 120° 27'.—Also, small islands in the Indian sea. S. lat. 6°. E. long. 71° 36'.—Also, three hills on the N.E. coast of Terra del Fuego; 9 miles W. of Cape St. Diego.—Also, three hills on the E. coast of New Holland, so called by captain Cook. S. lat. 31° 40'.—Also, three islands on the Spanish Main, near the Mosquito shore. N. lat. 11°. W. long. 82° 52'.

THREE Creek Run, a river of Virginia, which runs into the Nottoway, N. lat. 36° 36'. W. long. 77° 12'.

THREE Hill Island, a small island in the Mergui Archipelago. N. lat. 10° 13'.

THREE Hills Island, one of the New Hebrides, in the South Pacific ocean, about 12 miles in circumference. S. lat. 17° 7'. E. long. 168° 35'. See **HEBRIDES**.

THREE Island Harbour, a bay on the coast of Patagonia, in the Straits of Magellan; 8 miles N.N.W. of Bachelor's river.

THREE Islands, small islands in the East Indian sea, near the E. coast of Bintang. S. lat. 1° 10'. E. long. 105° 2'.—Also, small islands in the Indian sea, near the coast of Africa. S. lat. 4° 50'.

THREE Islands Bay, or Harbour, a bay on the E. coast of the island of St. Lucia.

THREE Kings, an island in the South Pacific ocean, near the N. coast of New Zealand, discovered by Tasman. S. lat. 34° 12'. E. long. 172° 12'.

THREE Rivers. See **TROIS Rivières**.

THREE Rivers Harbour, a bay on the E. coast of the island of St. John, in the gulf of St. Laurence. N. lat. 46° 8'. W. long. 62° 10'.

THREE Sisters, three small islands on the W. side of Chesapeake bay.—Also, small islands in the East Indian sea. S. lat. 5° 42'. E. long. 105° 41' 36'.

THREE Stone Oar, a rock near the W. coast of Cornwall. N. lat. 50° 11'. W. long. 5° 32'.

THREE Sugar Loaves, small islands in the Mergui Archipelago. N. lat. 9° 13'.

THRELKELDIA, in *Botany*, has been so named by Mr. R. Brown, in memory of Dr. Caleb Threlkeld, a Dublin physician, who published a *Synopsis Stirpium Hibernicarum*.

rum in 1727. This is an alphabetical catalogue, principally founded on the papers of Dr. Thomas Molyneux, or the communications of other people; nor does it, according to our judgment, entitle its editor to any scientific rank.—Brown Prodr. Nov. Holl. v. 1. 409.—Clafs and order, *Twiandria Digynia*. Nat. Ord. *Holeracea*, Linn. *Atriplices*, Juff. *Chenopodea*, De Candolle, Brown.

Eff. Ch. Calyx pitcher-shaped, with an abrupt inner margin. Petals three, membranous. Stamens oppofite to the petals, inferted into the receptacle. Capsule membranous, imbedded in the pulpy permanent calyx. Seed folitary, ovate.

1. *T. diffusa*. Spreading Threlkeldia.—Gathered by Mr. Brown on the fouth coast of New Holland, and in Van Diemen's ifland, growing on the beach. This is a fmall, diffufe, fmooth *frub*. *Leaves* alternate, femicylindrical. *Flowers* axillary, folitary, feffile, without *bractes*. *Seed* furnifhed with albumen, which is embraced by the circularly inverted embryo. *Brown*. We have prefumed to take for *petals*, though by no means pertinaciously, what Mr. Brown, led by the analogy of the natural order of the plant, confiders as mere fcales belonging to the *calyx*.

THRENGI, or THRENGES, in our *Ancient Customs*, a denomination given to vaffals, but not thofe of the loweft degree, but fuch as held lands of the chief lord; otherwife called *drenge*, or *drenches*.

“Quia vero non erant adhuc tempore regis Willielmi milites in Anglia, fed threnges; præcipit rex, ut de eis milites fierent ad defendendam ferram: fecit autem Lanfrancus threngos fuo milites, &c.” *Somm. Gavelk.*

The name was impofed by the Conqueror: for when one Edward Sharnbourn, of Norfolk, and others, were ejected out of their lands, they complained to the Conqueror, infifting that they were always on his fide, and never oppofed him; which, upon inquiry, he found to be true; and therefore he commanded that every one fhould be refored to their lands, and be for ever after called *drenches*, or *ibrenches*. *Spelm. Du-Cange.*

THRENODY, THRENODIA, formed of *ἄπνος*, *mournful*, and *ὄδρ*, *fong*, a mournful or funeral fong.

THRESHER, in *Ichthyology*, a name fometimes given to the fea-fox.

THRESHER, in *Agriculture*, a perfon employed in threshing out grain and other feed crops by means of the flail. See *THRESHING*, and *THRESHING-Machine*.

THRESHING, the act of beating out the corn or other produce from grain or other crops. The flail was the implement formerly ufed for threshing of corn, and which feparated the grain from the ftraw and hulks effectually and expeditiously; but which is now become mach too tedious and expenfive, as well as liable to many other objections, and always bruises a great many feeds, befides leaving many in the ears. It has been attempted to avoid thefe inconveniencies by proper machines provided with a number of flails, or other parts anfwering the fame purpofe, made to move by the power of water, wind, fteam, or horfes. Of thefe, various forts have been lately invented, and brought to very great perfection. See *THRESHING-Machine*.

Although there are many different methods made ufe of in feparating the grain from the ear of the corn, that by the flail is the moft general and common.

Sometimes two perfons thresh together; and where more than two are employed together, which is fometimes the cafe, there muft be frequent interruptions, and a confequent lofs of time. It is fuggelted alfo, that the tool by which this fort of bufinefs is performed, fhould be well adapted to

the fize and ftrength of the perfon who ufes it, for preventing prejudicial fatigue. The beft method of attaching the different parts of the implement together, is probably, it is thought, by means of caps and thongs of good tough leather. Iron is, however, fometimes employed. In the execution of the work, when the corn is bound into fheaves, it is ufual for the threshers to begin at the ear-ends, and proceed regularly to the others; then turning the fheaves in a quick manner by means of the flail, to proceed in the fame way with the other fide, thus finishing the work in a quick eafy manner by their becoming loofe and open.

It is, however, obferved by the author of the “*Experienced Farmer*,” that threshing with the flail is uncertain when moft carefully performed, for the thresher may beat a long time and not meet with every head, which with the machine it is hardly poffible to mifs; and that the grain wafed by the ufe of the flail is certainly great. In fhort, he is of opinion that the corn loft by threshing with the flail, is more than would pay for threshing it by the machine all over the kingdom.

In fome places it is the practice to thresh by the meafure of grain, as the bufhel, quarter, &c. while in others it is done by the threave of twenty-four fheaves, and in fome by the day.

In whatever way the farmer has this fort of bufinefs performed, there is always much neceffity for his conftant infpection, in order to prevent the frauds and impofitions that are too frequently practifed upon him by the perfons engaged in the execution of it.

The flail practice, however, from its being fo extremely flow, tedious, and expenfive, and at the fame time requiring a great number of labourers, is perhaps only capable of being had recourse to with advantage on the fmall kinds of grain-farms, that are cheaply fituated in regard to the command of workmen, and where the expence of having large machines would be much too great for the quantity of grain which they produce. But even in thefe cafes, if the fmall horfe or hand threshing engines that are conftituted on cheap fimple principles, and which occupy but little room, fhould be brought to perform the bufinefs in an eafy, expeditious, and effectual manner, which feems not improbable from the improvements that have been recently made in this fort of machinery, it will moft probably be to the advantage of fuch farmers to abandon it, as the faving in various ways muft foon repay them the expence of the machine, and at the fame time afford them a confiderable profit.

It is moreover ftated, that where threshing is performed by the flail, expenfive barn-floors, either of the fixed or moveable kind, will conftantly be neceffary; but that the latter fort may fometimes be capable of being converted to other purpofes, which may render it ufeful in other views and intentions, and thereby leffen the heavy charge of providing them. See *THRESHING-Floor*.

It is ftated by the author of “*Practical Agriculture*,” that the fuperiority of the method by machinery over that of the flail is very confiderable in many other refpects, befides thofe of its executing the work in a much more clean and perfect manner, more cheaply, and with much greater difpatch, fo as to admit of the farmer being prefent during the procefs in moft cafes.

It has been further faid, that the flail is a tool which is only fit for the rude or favage ftate of a people; while the threshing by the machine can be performed at any feafon, as when the weather is wet, and when no other fort of work can be done, efpecially of the out-door kinds; and it will employ women and children, or boys, as well as other

THRESHING.

sorts of labourers. By the use of it, the farmer is enabled to get the advantage of markets, as he has thereby the power of felling and delivering almost any quantity within a little time; and by threshing out and placing the corn in a secure store room or granary, the great loss often occasioned by vermin may be wholly prevented and removed. Numerous other beneficial consequences may likewise result from the practice of threshing by means of machinery, but particularly that of saving the heavy expence of raising and upholding many different large buildings of the barn kind, on extensive farms of the arable description.

It may be stated, that the writer of the Account of the State of Agriculture in the County of Kent, found, on having different parcels of wheat-straw, of thirty-six pounds each, threshed out clean by the flail, by different farmers, and the same weight of straw threshed after it came from the machine, the average produce of corn left in the straw by the common mode of threshing was half a pint in every thirty-six pounds of straw, more than that left in by the machine method. And that, besides, sufficient supplies of both corn and straw may at any time be almost immediately provided, either for the purposes of feed, the market, or the feeding of animals, without the other operations of the farm being in any degree interrupted. It is likewise obtained with much less waste of the grain, and with less danger of its being injured by being bruised. Likewise, that from the then increasing scarcity of labourers, the great advance in the price of labour in all the well-cultivated districts, and the impossibility of having this sort of work performed in a clean and exact manner by the flail, the necessity as well as utility of the machine are established. And it is further contended, that the principal obstacles to machines of this nature being more generally made use of, are those of expence in their construction and erection, and the littering slovenly practice which prevails in some of the more southern districts of harvesting or securing the grain crops in a loose uneven manner. But the first of these objections may probably, it is supposed, be obviated by the construction and introduction of hand, or one-horse, or ox-threshing machines; and the latter by the daily discoveries that are making in the improvement of this sort of machinery.

It is conceived, that the opposition that has been raised against this practice, on the ground of its being calculated to deprive and prevent the labourers of employment during the winter season, is scarcely deserving of notice, as experience has fully shewn that no injurious consequences can result from it, as there must always be work enough of other kinds at such periods, where farms are under a judicious mode of cultivation.

It is on the whole supposed, however, that the saving of expence in this mode of threshing over that of the flail, must differ much according to the nature and manner of constructing the machinery, the power by which it is wrought, and also on the state and condition of the grain at the time of performing the operation, as well as the full manner and regularity with which it is supplied and managed. By some farmers it is considered as nearly, if not quite, one half, while others make it much less than that proportion. But with the best constructed machinery, there can be little doubt but that it will be performed on an average of different sorts of grain, and different states of them, at less than one-third the expence of the flail method, without taking into the account any thing for the vast saving in grain, in which some reckon a profit of at least 5 per cent.; others, as equal to the seed and prices of threshing, which is somewhat more than half the price in the flail method; or either of the other operations that may

be performed at the same time with the same machinery, such as those of winnowing or cleaning the corn, cutting straw into chaff, bruising and grinding the grain for cattle food, breaking bones for manure, and various other purposes and works.

In addition to the advantages that have been chiefly considered in respect to these machines, there is another which, in the then scarcity of procuring labourers, and indeed at all seasons and times, must be of great importance to the farmer, which is that of their enabling him to perform his work with greater certainty and convenience, and at much less expence of labour. It has indeed been stated by a writer, in a late periodical work on farming, that with a machine, two labourers on a farm will be equal to four without it; as they are left at liberty, during the winter months, for performing various other sorts of farm labour.

It has already been noticed, that the charge of this sort of work with these machines will vary considerably, according to the manner in which they are constructed. In the Agricultural Survey of the County of Kent, the expences and produce of threshing *per day*, in different sorts of corn, with an engine of the common construction, without the late improvements, are stated in the manner following:

Estimate of Threshing Expences, &c. by the Machine.

<i>For Wheat.</i>		£	s.	d.
Eight men, at 1s. 4d. each	-	0	13	4
Four boys, at 1s. each	-	0	4	0
Four horses, at 2s. 6d. each	-	0	10	0
Cleaning and measuring 24 qrs. at 3d. each	-	0	6	0
		1	13	4

This is about 1s. 4d. *per quarter*, or nearly half the price of the flail method.

<i>For Barley.</i>		£	s.	d.
Cleaning and measuring 32 qrs. at 3d. each	-	0	8	0
Other expences, as above	-	1	7	4
		1	15	4

This is somewhat more than half the price of the flail method, this sort of grain having of late been usually threshed at about 1s. 6d. the quarter.

<i>For Oats.</i>		£	s.	d.
Cleaning and measuring 40 qrs. at 1d. each	-	0	3	4
Other expences, as before	-	1	7	4
		1	10	8

This is a little more than half the price of that by the flail; this sort of grain being commonly threshed at about 1s. 3d. *per quarter*.

The expences are here, however, calculated considerably too low for the succeeding times, as the men would *since* require 2s. or 2s. 6d. and the horses 5s. or 6s. each at least for the day.

But in the improved machinery of this kind fewer hands are required, and a number of other operations are performed

THRESHING.

formed at the same time, which greatly lessens the expences of executing the work.

In threshing with a powerful improved machine belonging to Mr. Harbottle, on the Riminham farm in Berkshire, according to the writer of the Agricultural Report of that district, the comparative calculations of expence and saving stand as below.

Estimate for Wheat.

	£	s.	d.
A man to feed the machine with sheaves, at per day	}	0	2 6
A woman to throw up the sheaves into the sheaf-helf, at per day			
A girl or boy to hand and unbind the sheaves to the man who feeds, at the same	}	0	0 8
A man to riddle or sift the corn from cockles, or small chaff, at			
A woman to assist him	}	0	0 8
Two men to remove the straw, and to make it up into bundles, at 2s. 6d.			
A boy to drive the horses, and attend to their paces, at	}	0	1 6
In all eight persons			
Four horses, at 7s. 6d. per day, a liberal allowance	}	1	10 0
Expence of threshing 20 qrs. which is done in the day of 12 hours			
Ditto by the flail, at 3s. 6d. per quarter, supposing a man can thresh a quarter in the day, which is too much	}	3	10 0
Saving by the machine in 20 qrs.			
Or by the quarter	}	0	1 4

Estimate for Barley.

Two men to feed and loose bands, at 2s. 6d.	}	0	5 0
Two women to pitch up and supply machine, at 8d. each			
Two women to riddle, at 8d.	}	0	1 4
Two men to remove straw, at 2s. 6d., and one boy ditto, at 1s. 6d.			
One boy to drive	}	0	1 6
In all nine persons			
Four horses, at 7s. 6d. each	}	1	10 0
Usual price by the flail, 2s. 2d. per quarter, 30 qrs. the quantity done in the day of 12 hours			
Saving on the above quantity	}	0	19 4
Or by the quarter			

Estimate for Oats.

Nine persons employed, as for barley, and the same number of horses	}	2	5 8
Usual price by the flail 2s. per quarter, on 40 qrs., the quantity done in the day of 12 hours			
Saving on the above quantity	}	1	14 4
Or by the quarter			

It should be noticed, that these calculations are made fully to the highest, which is so much the more in favour of the machine.

In some of the northern districts, the execution of this sort of business by the machine is sometimes undertaken by

labourers, the farmer finding horses. By this method, in Yorkshire, the work costs for wheat 1s. the quarter, and oats 6d. And in Northumberland they make use of a machine, which threshes at the rate of 33 bushels per hour, or 264 in the day of eight hours. In this machine, the expences in the attendance of the threshing and dressing parts of it being merely that of three women; one to feed in, another to hand the sheaves to the feeder, and a third to take away and riddle the corn after it is winnowed; consequently the threshing and dressing the above number of bushels only costs 1s. 6d., while the threshing the same quantity by the flail would be $\frac{7}{12}$ th part, or $10\frac{1}{2}$ bushels, which at 2s. the bushel is 21s.; to which must be added 2s. for the expence of a man and two women to assist in winnowing, which makes in all 23s.

But in the Agricultural Survey of the County of Norfolk, there is an account of the expence of threshing with the machine in comparison with that of the flail, which furnishes a very different result. The machine was built by a person from Leith in Scotland, for Mr. Bevan, and cost 100l.; and strongly shews, it is thought, that bad machines are worse than the old method of the flail.

Threshing by Means of the Flail.

	£	s.	d.
Forty coombs of barley, at 7d. come to	}	1	3 4
To dressing of ditto			
Fifty coombs of oats, at 6d.	}	1	5 0
Dressing ditto, at 1s. per score			
Forty coombs of rye, at 9d.	}	1	10 0
Dressing ditto, at 1s. per score			
Forty coombs of wheat, at 1s.	}	2	0 0
Dressing ditto			
	}	2	2 0

Threshing by the Machine.

Forty coombs of barley take eight horses, at 2s. 6d.	}	1	0 0
Ten men, at 1s. 6d. each			
To dressing ditto, five men one day	}	0	7 6
Thus barley costs more by 17s. 2d.			
Fifty coombs of oats take eight horses, at 2s. 6d.	}	1	0 0
Ten men, at 1s. 6d. each			
To dressing ditto	}	0	7 6
Thus oats cost more by 15s.			
Forty coombs of rye take eight horses, at 2s. 6d.	}	1	0 0
Ten men, at 1s. 6d. each			
To five ditto, at 1s. 6d. one day dressing	}	0	7 6
Thus rye costs more by 10s. 6d.			

THRESHING.

	£	s.	d.
Forty coombs of wheat take eight horses, at } 2s. 6d. - - - - - }	1	0	0
Ten men, at 1s. 6d. each - - - - -	0	15	0
Five ditto to dressing - - - - -	0	7	6
	2	2	6

And wheat costs more by 6d.

The calculations of the expences are here made greatly under the rate of wages and hire of horses which has since taken place.

The above should lead the farmer to be careful in putting up these machines; and to be certain of their being constructed in such a way, as to answer the purpose in a perfect manner before he begins the work.

It is well observed by Mr. Somerville, in the Agricultural Report of East Lothian, in calling the attention of the public to the unrewarded merits of Mr. Mickle, in bringing the threshing machine to a state of perfection, that it is computed, by those who have paid every possible attention to the subject, that in Britain about 7,500,000 acres are annually employed in raising grain, the produce of which, if averaged at three quarters *per* acre, amounts to 22,500,000 qrs.; and, as it is admitted that the surplus quantity gained by the use of threshing machines is at least a twentieth part more than when the flail is used, it will appear that 1,112,500 qrs. would be saved annually, were the whole of the grain in the kingdom threshed in that way; the value of which, if only calculated at 3s. *per* quarter, would be 1,781,250*l.*; to which adding the savings of expence, at 1s. *per* quarter, upon 22,500,000 acres, *viz.* 1,125,000*l.*, it would make the enormous sum of 2,906,250*l.* sterling; a fact almost incredible to any but those who have turned their attention to the subject, and are well acquainted with the great difference between the threshing-machine and the flail.

All sorts of grain should be in a proper, hard, dry condition, when it is to be threshed out, otherwise the work cannot be performed in a clean and perfect manner, whether it is to be executed by the flail or the machine.

It is a remark of the time of Lisle, founded on his own extensive experience, that wheat threshed in damp weather generally yields but little flour, with a great deal of bran, when it is ground; and that if it be put into sacks, it will grow muffy in less than three weeks, let the weather be ever so dry afterwards: but if, on the contrary, it be threshed when the air is perfectly clear and dry, it will keep well in sacks for a long time, especially if these are laid upon tressels high enough to secure them from the dampness of the ground or floor.

But for keeping of the meal or flour, in general, there is no better way than first to bolt and clean it from the bran or husks, which is apt to make it muffy, and then to tread it down as hard as possible, and head it up closely in clean, dry, tight, and well-bound casks, which must be laid in a cool dry place.

It may be noticed, that the beards of barley come off best, in threshing, when the sheaves or swarths of this corn have taken the dew before their being housed. It will keep well in the mow unthreshed for one year; but for making it into malt, which must be done before the heat of the summer comes on, it should not be kept above a year and a half, or at most two years: otherwise it will be filled with weevils or insects; unless it has been previously cured in a stove or kiln.

But oats, from their being defended with a double husk, are the grain least subject to harbour vermin. The best way to keep them after they are threshed, which should be done

when dry, is to dry them well on a kiln, and then to barrel them up in clean close casks.

As for beans and peas, they always thresh best after they have sweated in the mow, which they are very apt to do; as the whole crop of either of them never ripens altogether, the green parts heat, and communicate their ferment to the whole heap. The danger to be guarded against is, that they do not heat too much. For this reason, farmers generally choose to stack them without doors, rather than to house them; that they may be the more thoroughly dried by the sun and air. As beans are a very large seed, and consequently full of moisture, it is found best to let those that are intended for keeping, sweat and season in the mow until March, when they may be threshed without danger, for beans never give again, after they have once been thoroughly dried and hardened.

And vetches, when wanted for sowing immediately after they are cut, may be threshed very well on a hurdle, with a cloth; though they then be too soft, notwithstanding their being ripe, to be threshed on a floor, where the flail and the thresher's feet would bruise and break them.

In general, in the business of threshing, as the work proceeds, it will from time to time be necessary to remove all the long straw from the corn beaten out of it, which last always lies underneath, with a prong or fork, and then the pieces of straw, broken ears, &c. with a wooden rake. The remaining grain should then be shovelled up on one side of the floor, and the work be repeated till enough be threshed out to make what is commonly called a clearing. The heap should then be wholly passed through a wide sieve, which retains only the bits of straw, and such fragments or ends of the ears as have escaped the flail. These frequently contain some good corn, and form an useful fodder for most sorts of animals, being what are commonly called *cavings*, as seen below.

Much labour may often be saved in the use of the sieve by fastening a loop to its rim, and resting it thereby on a hook suspended by a rope. This will sustain half the weight of the corn, and the necessary circular motion may more easily be given to it.

After much threshed grain has thus accumulated on the threshing-floor, and the short straw and chaffy matter have been separated from it, as just noticed, by passing it through a wide riddle or sieve for the purpose, which should always be done before too much grain has been collected, as in that way the bruising of it is more effectually prevented; it must be put by to afford more room. The short chaffy substance thus separated from the grain is in some districts denominated *cavings*, or *caving-chaff*, and is capable of being employed with advantage, as seen above, in the feeding of horses, or neat cattle and sheep. When this has been done, the loose grain should be thrown into a chamber or other place conveniently formed for receiving it, where it should remain till a sufficient quantity has been collected to render the clearing and cleaning of it by some kind of machine for the purpose, requisite. But the improved threshing machines render this unnecessary, as they dress or clean it at the same time it is threshing out. See *WINNOWER Machine*.

Furze tops in their young states of growth are in some northern situations beat or threshed by the flail, and in that way bruised as horse-food, where proper machinery for this purpose is not at hand. The work-horses during their use have little other food, it is said, though performing great labour.

From the whole of what has been said, it is evident that the farmer should always consider well before he decides on the mode of threshing which may be the most proper and
advan.

THRESHING.

advantageous, as well as the most suitable, to the sort of farm which he holds.

THRESHING-Floor, the floor on which grain is threshed out in the barn or other place. All floors of this sort should be well formed and constructed, of whatever sort of materials they are made, as without it they give way and fall to pieces. When the material employed in this intention is wood, the timber should always be of the best kind, and well seasoned, being put together in a careful and firm manner; and when of the earthy kind, the different matters be well reduced, wrought together, and laid up for some length of time before the floor is formed, being then laid down in a smooth even manner, and made firm and solid by frequent ramming with a proper tool for the purpose, until the flooring substance, whatever it may be, becomes quite dry.

It has been observed, that as grain is threshed out by machinery, from the circumstance of its being separated from the straw immediately, and not permitted to remain upon the floor for above an hour or two, when brought to market, is always much drier, looks better, and brings a higher price than that which is threshed by the hand, and suffered to remain upon the floor for weeks, where it becomes musty, loses its colour, and is so raw, that much of it is bruised and rendered useless in the working. Therefore, if the flail-mode of threshing is still pursued, it is supposed that the inconveniences above-mentioned may, in some degree, be remedied, by paying proper attention to the materials of which the floor is made, and raising it sufficiently above the reach of moisture. Where the barns are very extensive, and the price of wood uncommonly high, as is the case at present, a very good and durable threshing-floor may sometimes be made by laying an uniform stratum of round gravel, covering it with a coat of well-tempered clay; above which, a mixture of clay, brick-dust, forge-ashes, and a small proportion of lime, will make it a hard uniform floor, proper and suitable for the purpose of threshing upon. It is observed that the brick-dust and forge-ashes should previously be beaten very small, and well incorporated with the clay, using a sufficiency of water to bring the whole to the consistence of mortar; in that state the lime, having been previously slaked, should be incorporated with the other ingredients; the whole smoothed over with the back of the spade, and allowed to remain in a round heap for two or three weeks, at the end of which time it should be turned over in the same manner as plaster lime, and after being rendered sufficiently soft with water, it may be spread upon the floor, an operation that will require some pains on the part of the workman. The floor, in the first instance, should have the coat of clay, that is laid above the gravel, rendered perfectly smooth and uniform, by rolling, beating, or otherwise; the finishing coat, composed of the mixture above-mentioned, may then be applied, taking care to break the surface of the clay with shallow lines, in the way practised by plaiters, for the purpose of making one coat adhere to another in a firm and perfect manner.

Many other sorts of materials, somewhat of this nature, are made use of for threshing-floors in different districts of the kingdom.

The following plan has been suggested as the means of excluding rats and mice from the barn and threshing-floors. First, that when the floor is entirely of wood, the space between the sleepers, upon which the boards are laid, should be entirely filled with washed gravel, well beat down, an operation which, when properly done, will effectually prevent the entrance of either rats or mice; where this precaution is not taken, when the floor is laid, openings should be

made at the bottom of the wall large enough to admit cats, a contrivance that will have the two-fold effect of destroying the vermin, and affording a free circulation of air. Secondly, that when the floor is of clay, the vermin generally burrow under the foundation, and have the entry to their retreats at the bottom of the wall: in such cases, their access into the barn will be, in some measure, if not entirely, prevented, by mixing a considerable quantity of broken glass with the materials with which the threshing-floor is made. It does not appear necessary to mix the glass with the clay over the whole floor; perhaps two feet from the wall quite round will be sufficient. And thirdly, that the top of the wall, as furnishing a temporary retreat for vermin, deserves also to be noticed: in every instance it is customary for the mason to level the top of the wall previous to the roof being put on, which, when the building is finished, is left in that state, by which a considerable space remains for the shelter of rats and other vermin: to prevent this, as soon as the roof is finished, the building of the wall on the inside should be continued upwards till it joins the roof, to which it should be closely united by hard plastering. It is supposed, by these precautions, and smooth plastering, the walls of barns as well as the threshing-floors may be preserved free from vermin.

THRESHING-Machine, an engine of the mill kind, contrived for the purpose of threshing grain, seeds, and pulse out of the straw or the ear.

This is a sort of mill or machine that has been chiefly constructed on the same principles as those of the flax-mill, and which is capable of being wrought by different powers, as those of horses, oxen, wind, water, and steam; but those of water and animals are the most proper and convenient in most instances: in some cases, the grain being beaten or swung out of the ears by means of beaters attached to a cylinder that has much velocity, while in others it is rubbed out by suitable means against confined cylinders, as will be more fully seen and explained in what is said below.

There is some reason to suppose, that the original hint or notion of these mills or machines, was derived a long time ago from Holland or the Low Countries, and thence brought into the northern parts of this country, where the different parts of the machinery of them have since been gradually undergoing much modification and improvement, to render them more suitable and efficient for the purpose; so that they have now attained a considerable state of perfection in most parts of the kingdom. The first of these improved machines was, as Mr. Somerville says, invented by a Mr. Menzies, brother to the then sheriff depute of the county: the machinery was driven by a water-wheel, which put in motion a number of flails of the same kind with those used in threshing by the hand. Trials made with these machines were so far satisfactory, that a great deal of work was done in a given time, but owing to the velocity required to do the work perfectly, they soon broke, and the invention fell into disgrace.

Some time in the year 1758, another attempt was made by a farmer in the parish of Dumblane, in Perthshire. His machine was constructed upon principles similar to the flax-mill, having an upright shaft with four arms inclosed in a cylinder, three feet and a half in height and eight in diameter, within which the shaft and its arms were turned with considerable velocity by a water-wheel. The sheaves, being presented by the hand, were let down from the top upon the arms, by which the grain was beat out, and together with the straw descended through an opening in the floor, where they were separated by riddles and fanners, also turned by the water-wheel.

And

THRESHING-MACHINE.

And it is added, that, about twenty years after this, a third attempt was made by a Mr. Elderton, near Alnwick, and a Mr. Smart, at Wark, both nearly about the same time. Their machines were so constructed as to act by rubbing, in place of beating out the grain. The sheaves were carried between an indented drum, about six feet in diameter, and a number of rollers of the same description ranged round the drum, towards which they were pressed by springs, in such a way as to rub out the grain when the drum was turned round. Upon trial, this method of construction in these machines was also found defective, as along with its doing very little work in a given time, it bruised the grain, and so materially hurt its appearance, as to lessen its value considerably in the markets.
